versity centered in areas of varied topography—the Andes, Guayana, and south-central Brazil. The neotropical Memecylaceae, on the other hand, are centered in the Amazonian lowlands, where they appear adapted to different soil types (pers. obs.). The very early shift from anemochory to zoochory in the Melastomataceae was probably one of the reasons for their success in the understory of closed forests, where animal dispersal is more advantageous than wind dispersal. (The capsular-fruited tribes are much more diverse in open habitats and have relatively few species in forests.) The crucial points in the radiation of large groups within the Melastomataceae, besides their different seed-dispersal strategies, have been the acquisition of particular plant architectural, indument, and leaf venation characters. Because adaptations to different pollinator types played such a limited role in the radiation within the two families, the floral biological data cannot be used to support either of the two suggested phylogenies for the Melastomataceae (Wurdack in Welle & Koek-Noorman, 1981; Vliet et al., 1981).

FLORAL NECTARIES IN MELASTOMATACEAE AND THEIR SYSTEMATIC AND EVOLUTIONARY IMPLICATIONS[1]

Bruce A. Stein[2] *and Hiroshi Tobe*[3]

ABSTRACT

The vast majority of the 4,500–5,000 species in the primarily tropical family Melastomataceae do not produce floral nectar, instead relying on pollen as the pollinator reward. To determine the anatomical basis for nectar production in the relatively few nectar-producing taxa, we examined 40 species in 17 genera representing known nectar producers and genera and species not reported to secrete nectar. Our anatomical investigations included six species in three genera of Memecylaceae, a family traditionally placed within Melastomataceae. We also conducted field observations to clarify the site of nectar secretion in several genera. No structural nectaries (derived from differentiated parenchyma) were detected in any of the species examined. Rather, most nectar-secreting species appear to produce the nectar from a thickened staminal vascular bundle. Within the order Myrtales, this type of nonstructural androecial nectary is limited to Melastomataceae and is apparently very rare among angiosperms as a whole. Two additional methods of nectar production in Melastomataceae were revealed: secretion from the petal tips in *Medinilla*, and, although field confirmation is still required, from the stigma in *Miconia*. Given the ancestral myrtalean nectary type, it seems clear that structural nectaries were lost in the evolutionary lineage ancestral to Melastomataceae and Memecylaceae. In most nectar-producing Melastomataceae the re-evolution of nectaries appears to be related to a shift in pollinator interactions, specifically from vibratile-pollination bees at lower elevations to vertebrates at higher elevation. We consider the independent development of nectaries in several lineages of Melastomataceae to be the most parsimonious explanation for the diversity of nectary types within the family and for the scattered phylogenetic positions of nectar-producing taxa.

The family Melastomataceae, with ca. 200 genera and 4,500–5,000 species, is the largest in the order Myrtales. This primarily tropical family is distributed worldwide but particularly well represented in tropical and subtropical areas of the New World. Most members of the family produce no floral nectar, relying instead on pollen as the principal pollinator reward (for review see Renner, this volume). Species in at least two genera, *Tibouchina* (= *Purpurella*) (Ule, 1896) and *Brachyotum* (Lagerheim, 1899), however, have long been known to produce nectar. Additional observations of nectar production, or presumed production, have been made more recently on these and several other melastome genera, including *Blakea* (Lumer, 1980; Lumer & Schoer, 1986), *Huilaea* (Snow & Snow, 1980), and *Miconia* (Mori & Pipoly, 1984). Most reports that note the location of nectar secretion within the flower generally found the nectar to emanate from the stamens. This strongly contrasts with the situation in most myrtalean families in which floral nectaries are located either on the floral tube, the gynoecium, or at the floral tube–gynoecium junction.

Floral nectaries of Melastomataceae have been little studied, and nothing has been reported pre-

[1] Our special thanks to Peter H. Raven for his continued help and encouragement in this study. For contributing fixed flower material for anatomical observations, we express gratitude to Frank Almeda, Paul E. Berry, Dennis E. Breedlove, Barbara G. Briggs, H. Churchill, Enrique Forero, Michael H. Grayum, William A. Haber, Barry Hammel, Blas F. Hernaez, Peter C. Hoch, A. H. M. Jayasuriya, J. F. Maxwell, Gordon McPherson, Bruce W. Nelson, Juan V. Pancho, Ching-I Peng, Barry Prigge, George Schatz, James Solomon, Kenneth Sytsma, and Elsa Zardini. We also thank William H. Haber, Cecile Lumer, Michael H. Grayum, and Susanne Renner for their field observations and comments on nectar secretion, and John J. Wurdack for identification of field-collected plants. We are grateful to Susanne S. Renner, John J. Wurdack, and Frank Almeda for comments on earlier drafts of this paper. This study was supported by National Science Foundation Grant BSR 85-18906 to Peter H. Raven and National Science Foundation Doctoral Dissertation Improvement Grant BSR 84-13912 to Bruce A. Stein.

viously about their anatomical structure. The primary purpose of this study is to elucidate the structure of Melastomataceae nectaries through anatomical examination and to confirm the unusual location of nectar secretion through field observations. Our investigation of floral nectary structure extends to representative genera of Memecylaceae, a family traditionally included in Melastomataceae as a tribe or subfamily. The anther connective of Memecylaceae contains a distinctive depressed gland structure that had previously been described as a nectary (Burck, 1891; Subramanyam, 1949). In *Mouriri*, however, these glands have recently been found to secrete a lipid-rich substance, suggesting that they are elaiophores (Buchmann & Buchmann, 1981).

Materials and Methods

We examined anatomically flowers of 40 species in 17 genera of Melastomataceae, representing known nectar producers and genera and species not reported to secrete nectar. In addition, six species of Memecylaceae in three genera were investigated. FAA-fixed collections were made by the authors and by numerous collaborators worldwide (Table 1).

After dehydration through a t-butyl alcohol series and embedding in Paraplast with MP 57–58 C°, flowers (and sometimes stamens alone) were sectioned transversely and longitudinally at 8–10 μm thickness; the sections were stained with hematoxylin, safranin, and fastgreen FCF and were mounted with Entellan. Dark staining by hematoxylin represents a concentration of cytoplasm in cells, indicating high metabolic activity such as seen in active nectaries. In other families of the Myrtales, this staining method has fully demonstrated the location and size of nectariferous tissue (Tobe, pers. obs.); if present, nectaries are thus easily distinguished from other tissue by their dense staining.

We noticed that certain species, particularly those known to secrete nectar, have a conspicuously thickened staminal vascular bundle. Thus, for comparative purposes, the thickness of the staminal vascular bundle is presented as a relative value (Table 1). The "relative thickness" of stamen vascular bundles is calculated as: radial thickness of the vascular bundle (t)/radial thickness of the filament (T). Calculations were made on the basis of two or three stamens. Relative thickness values are presented as a range, since the thickness of the filament and the vascular bundle can differ at varying points along the same filament.

Field observations of nectar secretion in *Brachyotum*, *Chalybea*, and *Tibouchina* were conducted while field collecting floral material for this study. Fresh flowers were examined for evidence of nectar, and the location of nectar secretion within the flower was noted. Nectar quantity and sugar concentration were measured using microcapillary tubes and a Reichert temperature-compensated hand refractometer (model 10431). Nectar sugar concentration measurements (% brix) were subsequently converted to sucrose-equivalents (weight by total weight).

Results

We did not detect densely staining structural nectaries in the flowers of any of the species examined of Melastomataceae and Memecylaceae. Three significant features were noted, however. First, stamens of some melastomes, particularly those known to secrete nectar, have a markedly thickened vascular bundle in relation to the filament or anther connective. Relative thickness of staminal vascular bundles of nectar-producing and non-nectar-producing species are presented in Table 1. The relative thickness values of staminal vascular bundles in nectar-producers normally exceed 0.3 (mean 0.34), whereas most other melastomes examined range between 0.1 and 0.3 (mean 0.23), a statistically significant difference ($P < 0.001$). Second, although no densely staining structural nectaries were found, many of these thickened vascular bundles showed relatively dark-staining phloem cells, indicating that they are cytoplasm rich and may be fulfilling a nectary function. Third, many of the nectar-secreting species have external slits that develop on or near the geniculum of the filament and that may represent a nectar emission pathway.

Information on the site of nectar secretion and on known or putative pollination vectors for nectar-producing Melastomataceae is summarized in Table 2. Examined genera that are known or strongly suspected to produce nectar are discussed individually below. Members of several other genera may also secrete nectar but were not examined. These include two additional Andean genera that hummingbirds have recently been observed visiting, *Centronia excelsa* (Bonpl.) DC. (Neill, pers. comm., 1987) and *Meriania tomentosa* (Cogn.) Wurdack (van der Werff, pers. comm., 1987).

MELASTOMATACEAE

Blakea. Three species of *Blakea* were examined anatomically, with *B. chlorantha* Almeda known

to produce nectar. Two additional nectar-producing species have recently been reported, *B. austin-smithii* Standl. and *B. penduliflora* Almeda (Lumer & Schoer, 1986). There is some disagreement concerning the site from which nectar is secreted in this genus. Lumer (1980, and pers. comm., 1985) stated that in *B. chlorantha* nectar appears to be secreted in the area at the base of the stamens, either at the junction of the filament and floral tube or at the base of the filaments. According to Haber (pers. comm., 1985), however, nectar is secreted on the abaxial surface of the filaments (the side facing the corolla wall), with the nectar forming thick droplets between the filament and the corolla.

Anatomical sections of *Blakea chlorantha* flowers do not show a densely staining nectary anywhere on the floral tube wall (Fig. 1), nor do stamens have an externally or internally differentiated nectariferous structure (Figs. 2, 3). Stamens are folded inward in bud, with a geniculum present just above the midpoint. Slitlike structures are present on the adaxial surface of the geniculum (arrows in Figs. 1–3). The relative thickness value of the vascular bundles is fairly low (0.21–0.27) compared with other nectar producers (Fig. 5). These vascular bundles, however, are relatively densely staining, particularly in the upper part of the filament and at the connective (Figs. 3–5). A major part of the staminal vascular bundle appears to consist of small, cytoplasm-rich phloem cells. Parenchyma cells surrounding the staminal vascular bundle are not specialized (Figs. 4, 5), suggesting that they are not nectariferous.

Stamens of *Blakea* sp. nov. (fide F. Almeda) and *B. foliacea* are folded inward in bud at the anther–filament junction, and filament slits are not present. Although, like *Blakea chlorantha*, they have a thin more or less densely staining vascular bundle, they differ in that the staminal vascular bundle is surrounded by a thick-walled tanniferous epidermis and by some underlying tanniferous cell layers. *Blakea* sp. nov. and *B. foliacea* stamens are unlikely to secrete nectar through such tanniferous tissue, and nectar production has never been reported in either of these two species.

Brachyotum. All *Brachyotum* species investigated in the field were found to produce nectar,

TABLE 2. Summary of data on nectar secretion and pollinators in nectar-producing Melastomataceae.

Species	Nectar Secretion Site	Time of Secretion	Pollinators	References

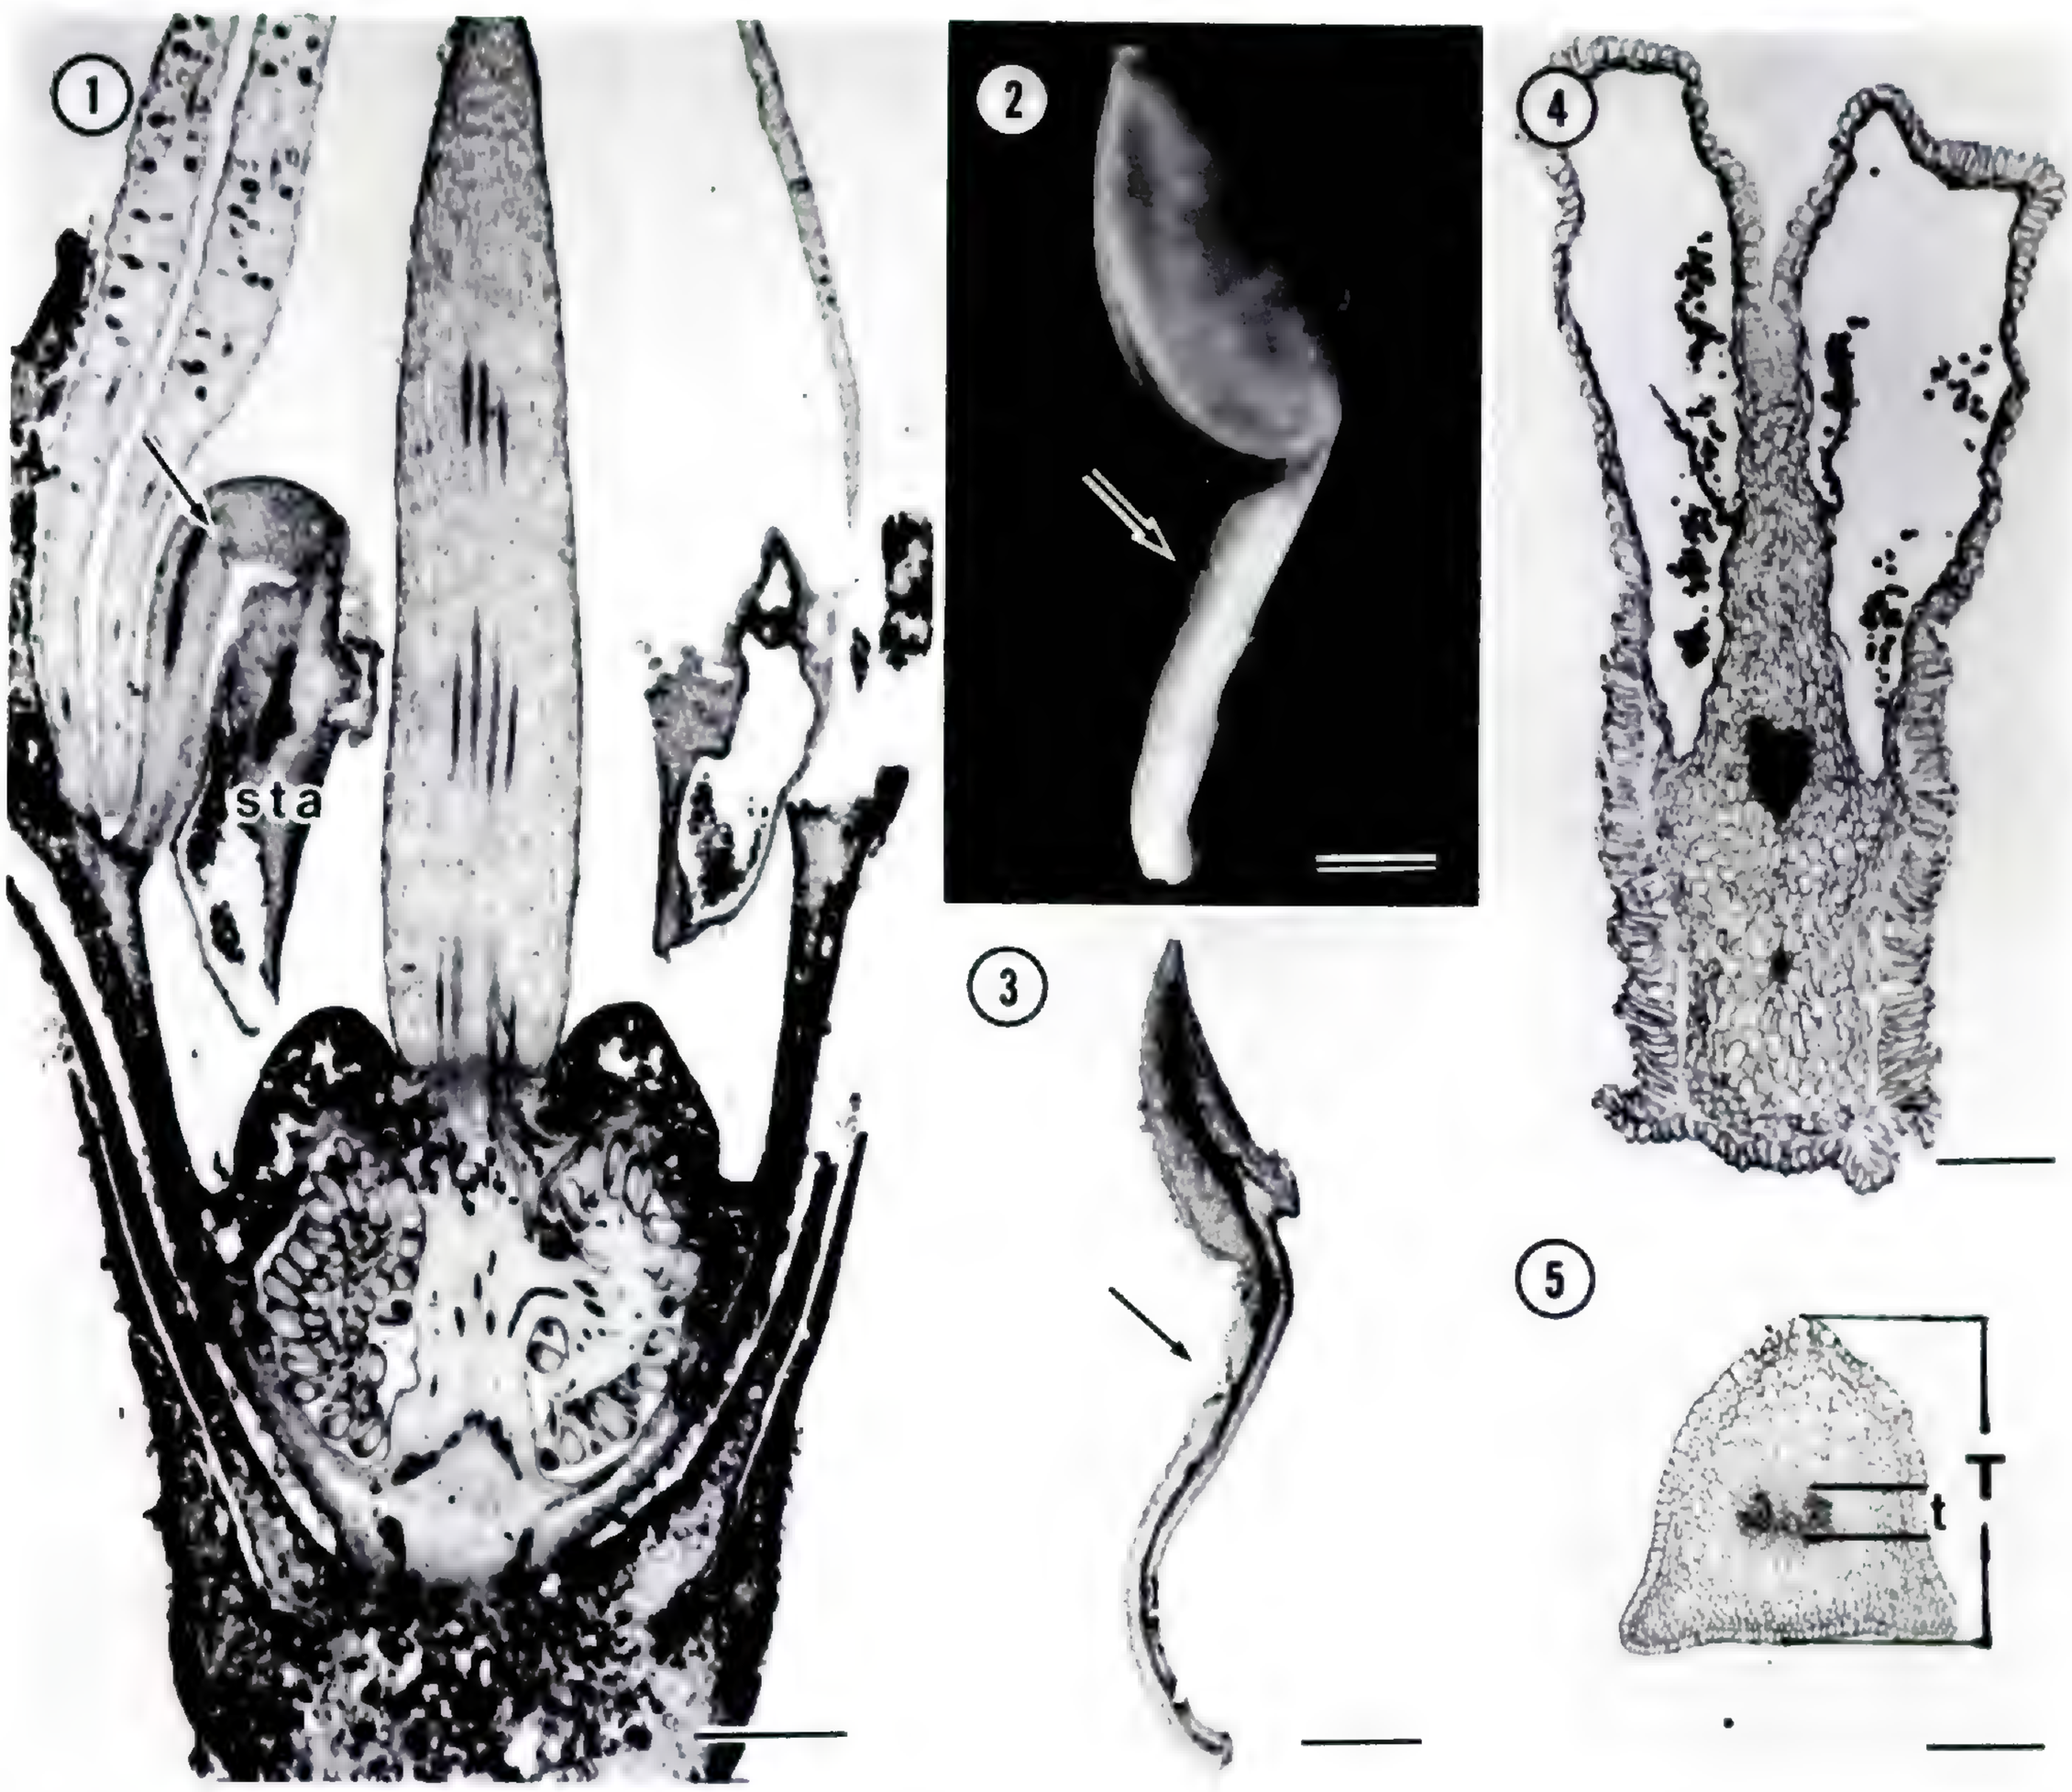
confirming previous reports (Lagerheim, 1899; Vogel, 1957; Wurdack, 1965), and it is likely that this entire Andean genus is nectariferous. From field observations, the nectar appears to be secreted by the filament at the slitlike structure located on or just below the geniculum on the adaxial filament face (Fig. 6) and forms large droplets suspended between adjacent pairs of filaments. Nectar concentration ranged from a high of 20–22% sucrose-equivalents in *B. ledifolium* (Desr.) Triana to a low of 15–16.5% in *B. campanulare* (Bonpl.) Triana, values consistent with most hummingbird-pollinated flowers (Baker, 1975).

Anatomical sections of stamens do not show any differentiated nectariferous structure in the filaments. Stamens of *Brachyotum ledifolium* have a thick vascular bundle running the length of the filament (Fig. 7) to the connective (Fig. 8). The staminal vascular bundle is densely staining and contrasts with the surrounding nonspecialized parenchyma cells. All other examined species of *Brachyotum* contain a similar thick, densely staining staminal vascular bundle: *B. campanulare* (Fig. 10), *B. lindenii* Cogn., *B. microdon* (Naud.) Triana, and *B. sanguinolentum* (Naud.) Triana (Fig. 9). This similarity in staminal anatomy suggests that all these species exude nectar from the filament.

Chalybea. *Chalybea* is a monotypic genus of the Colombian Andes closely related to, if not congeneric with, the nectar-producing genus *Huilaea*. Poorly known and consisting only of *C. corymbifera* Naud. (= *Pachyanthus corymbiferus* [Naud.] Cogn.), *Chalybea* recently has been resurrected on the basis of material newly collected for this study (Wurdack, 1988). We have observed nectar secretion from *C. corymbifera* and measured the nectar sugar concentration at 16.5% sucrose-equivalents. Pinpointing the site of secretion is problematic. Nectar was collected from the summit of the inferior ovary; however, the nectar was observed and measured several hours after the normally pendulous flowers were collected and could have migrated to this location. Stamens are bent inward in bud and have neither a pronounced geniculum nor filament slits (Figs. 11, 12). Anatomical sections do not show a differentiated nectariferous structure at the ovary summit (Fig. 11). While stamens do not have either externally differentiated structures or densely staining nectariferous tissue (Figs. 11, 12), they do contain a thick vascular bundle running through the filament (Fig. 14) to the connective (Fig. 13), suggesting staminal secretion. Tanniferous parenchyma cells surrounding the staminal vascular bundle appear unfavorable



FIGURES 1–5. *Blakea chlorantha*.—1. Longitudinal section (LS) of flower. –2. Stamen.—3. LS of stamen. —4,5. Transverse sections (TS) of anther and of filament. Arrows in Figures 1–3 indicate a depression or break formed at the inner side of the bend. Abbreviation: sta, stamen. T and t in Figure 5 are thickness of filament and of vascular bundle respectively, which are measured for calculation of relative thickness of staminal vascular bundles (see text for explanation). Scale bars = 1 mm in Figures 1–3; 0.2 mm in Figures 4, 5.

for secretion of nectar. These tanniferous cells, however, are much less conspicuous in the lower part of the filament, and nectar thus may exude from the filament in this location, perhaps accounting for its observed presence on the ovary summit.

Huilaea. Snow & Snow (1980) reported nectar production by *Huilaea macrocarpa* Uribe and measured the nectar sugar concentration to range from 12 to 16% with a mean of 13.4%. No information was provided as to the precise location of nectar secretion in these pendulous flowers.

Tibouchina. Nine species of *Tibouchina* were examined, including the Andean *T. grossa*, which is known to produce nectar. Brazilian *Tibouchina* species reported to secrete nectar include *T. cleistoflora* Ule, *T. hospita* (DC.) Cogn., and *T. itatiaiae* (Wawra) Cogn. (Ule, 1896). Our observations of nectar secretion in *T. grossa* differ somewhat from those of Vogel (1957), who considered the nectar to exude from the inner wall of the floral tube below the insertion of the stamens. *Tibouchina grossa* flowers are open-campanulate and oriented horizontally with all stamens arranged in a half-circle in the lower side of the corolla. We observed nectar droplets forming on the adaxial surfaces of the filaments near the geniculum. The drops are at first suspended between adjacent filaments and occasionally between the filaments and style. The rather copious nectar then flows down the filaments to collect either in the floral tube or on the convex lower petals. We measured sugar concentration of *T. grossa* nectar at 14.5% sucrose-equivalents.

No densely staining differentiated structure was found in the filaments of *Tibouchina grossa* (Fig.

15). Instead, stamens of *T. grossa* have a thick, densely staining vascular bundle surrounded by nonspecialized parenchyma cells (Figs. 16, 17). Relatively thick staminal vascular bundles are observed in all *Tibouchina* species investigated (see Table 1), although nectar production has so far not been reported in those other species.

Medinilla. The Old World genus *Medinilla* includes certain species that morphologically appear to be good candidates for bird pollination. We examined anatomically one such species, *Medinilla fuchsioides* Gardn., but found the staminal vasculature to be unexceptional. Subsequent to this, however, we found cultivated material of *M. magnifica* Lindl. at the Berlin Botanical Garden to secrete nectar from the petal tips. Anatomical investigations of this very unique nectar secretion method are currently under way (Tobe et al., in prep).

Miconia. In discussing a mass flowering episode of *Miconia minutiflora* (Bonpl.) DC, Mori & Pipoly (1984) reported the presence of nectar as a pollinator reward in this species. In other localities, however, this lowland species has not been found to secrete nectar (Renner, 1983).

Only young buds of *Miconia minutiflora* were

available for the present study. Anatomical sections of this material indicate no structure likely to produce nectar in either the stamens or around the floral tube–gynoecium junction (Fig. 18). Flowers are very small, with the filaments supplied by a relatively thin vascular bundle (Fig. 19). Anatomical sections show, however, that *M. minutiflora* has a remarkably conspicuous stigma supplied by ample, densely staining vascular tissue (Fig. 18).

Hummingbirds have been observed visiting *Miconia melanotricha* (Triana) Gleason (Almeda, pers. comm., 1986), and this species may produce nectar. The flowers appear morphologically well suited for hummingbird pollination, given their large size (10–15 mm in diameter and 23–25 mm long) and red petals. This species also has longitudinally dehiscent anthers rather than the apically poricidal anthers typical of bee-pollinated melastomes. Anatomical sections do not show densely staining structures or tissue, and the stamens have a thin vascular bundle (Fig. 21). As in *M. minutiflora*, however, the stigma and supporting vascular tissue are unusually densely staining (Fig. 20).

Miconia robinsoniana Cogn. was reported to produce nectar in a survey of the foraging ecology of the Galápagos Islands carpenter bee, *Xylocopa darwinii* (Linsley et al., 1966). Subsequent observations of this species have not reconfirmed the presence of nectar (McMullen, pers. comm. in Renner, this volume). During our own field investigations of this species, no suitable material could be located to resolve this question. An additional, as yet unidentified, *Miconia* species from lowland Amazonia has recently been reported to produce nectar (Roubik, pers. comm. in Renner, this volume).

MEMECYLACEAE

Memecylon and *Mouriri* have a peculiar depressed gland on the backside of the anther connective (Figs. 22, 24). This structure was early described as a nectary (Burck, 1891; Subramanyam, 1949; Venkatesh, 1955) but recently has been hypothesized to be an elaiophore, or oil-producing gland (Buchmann & Buchmann, 1981). Anatomical sections reveal this gland to be composed of more or less radially enlarged epidermal cells, which are clearly distinguishable from other cells of the connective (Figs. 23, 25).

Pternandra is variously included in or excluded from the Memecylaceae. Its uncertain status is based largely on the absence of the anther connective glands found in other members of Memecylaceae. The two species examined in this study, *P. caerulescens* Jack. and *P. echinata* Jack., lack these gland structures on the surface (Figs. 26, 27) and in section (Fig. 28).

Discussion

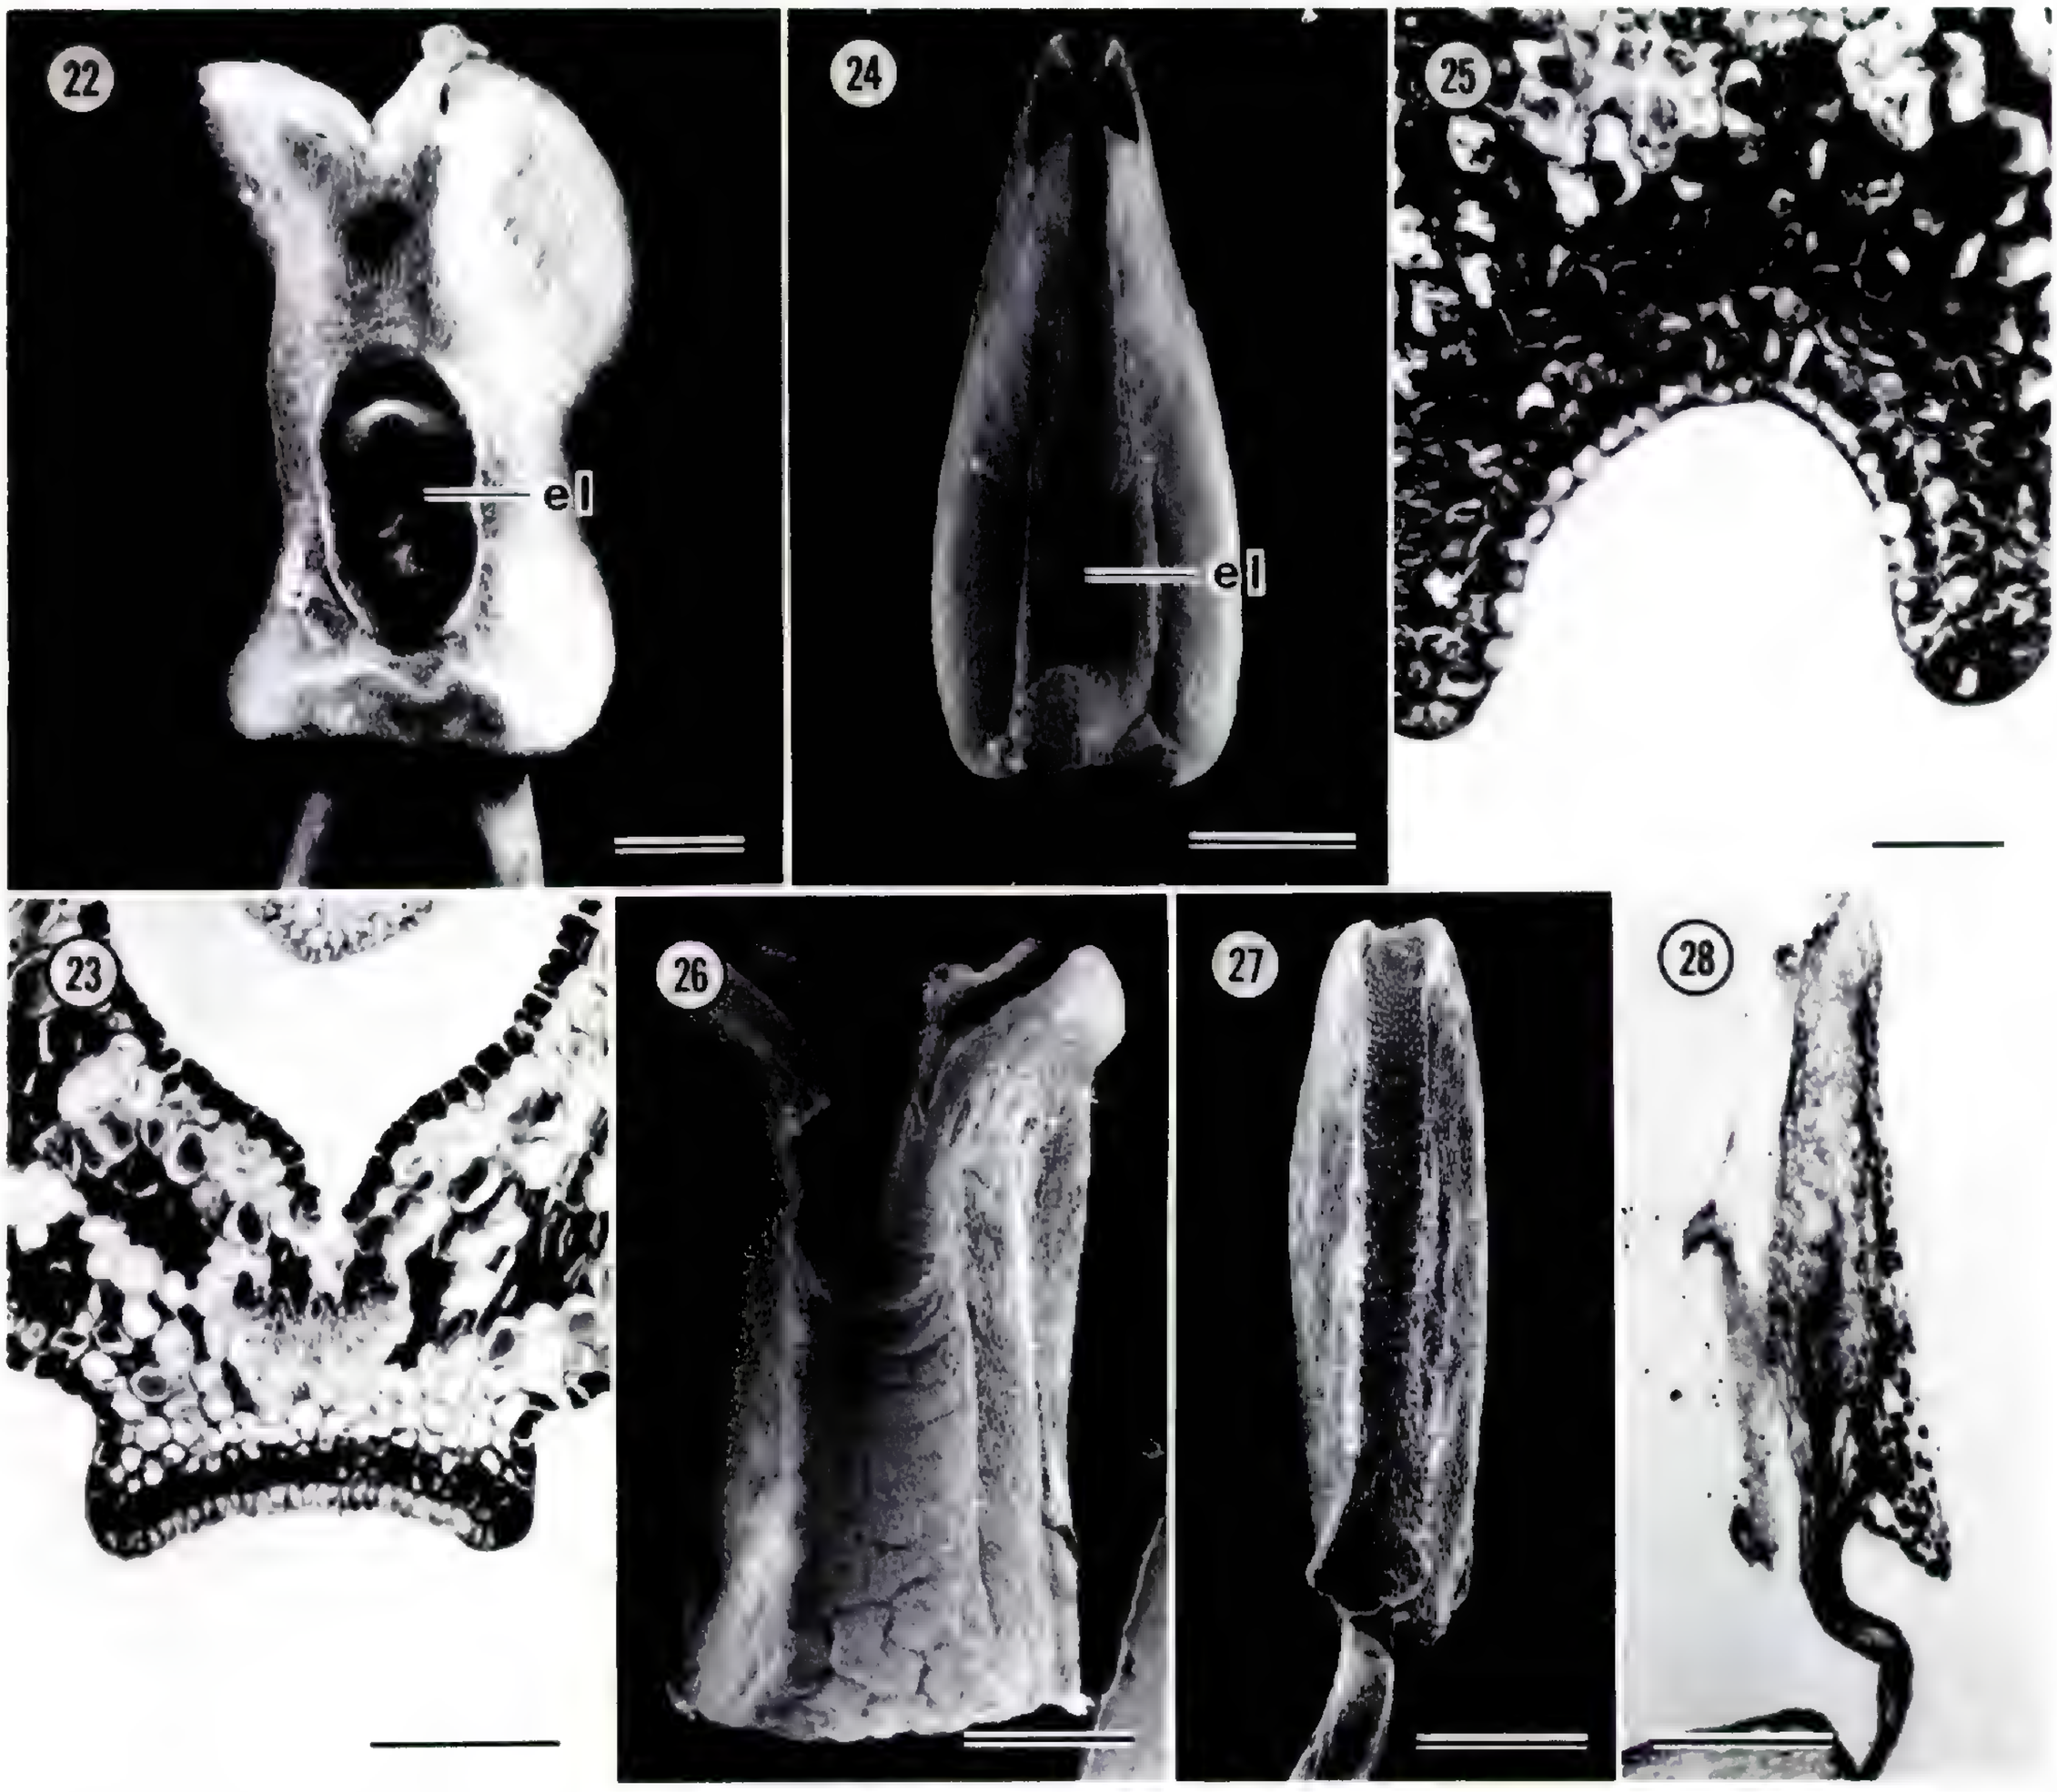
POSITION AND STRUCTURE OF FLORAL NECTARIES IN MELASTOMATACEAE

The present study shows that, in contrast to nearly all other myrtalean families, Melastomataceae lack histologically differentiated nectariferous tissue either on the inner surface of the floral tube, on the gynoecium, or at the floral tube–gynoecium junction. While nectar production in Melastomataceae is rare, a diversity of unusual nectary types are implicated, including secretion from the stamens, petals, and perhaps stigmas. Most documented nectar-producing melastomes secrete nectar from the stamens, although we did not find any differentiated nectariferous structures or tissue in that organ. On the basis of observations and anatomical structure, we thus conclude that in most nectariferous Melastomataceae nectar is produced by a nonstructural nectary consisting solely of the staminal vascular bundles.

Compared with melastome species generally, stamens of nectar-producers have a much thicker vascular bundle containing many small, densely staining cytoplasm-rich phloem cells. An ultrastructural survey of these cells could offer additional evidence of their nectar-secreting capability, since there is a clear connection between cytological constituents and processes of nectar secretion (for review of ultrastructural features see Fahn, 1979).

The nonlocalized nature of these androecial nectaries may help resolve the conflicting reports about the specific sites of nectar secretion (Table 2). If nectar is produced by the staminal vascular bundle, it could emanate from almost anywhere along the stamen. Additionally, if the direction of the nectar stream within a stamen is affected by gravity, the secretion site could differ between stamens and among individual flowers.

Several observers, including one of us (B.A.S.), have noticed that in certain genera (e.g., *Brachyotum* and *Tibouchina*) the location of nectar secretion appears to be closely associated with a small slit in the adaxial surface of the filament (see arrows in Figs. 1–3, 6). The development and significance of these slits is somewhat controversial. We found no anatomical differentiation of this structure. Since stamens in Melastomataceae are folded or bent inward in bud, becoming more or less straight at anthesis, the observed slitlike structures may form spontaneously and be unrelated to nectar secretion.



FIGURES 22–28. *Memecylon*, *Mouriri*, and *Pternandra*.—22, 24. Scanning electron micrographs (SEM) of anthers of *Memecylon caeruleum* and *Mouriri nervosa*, showing anther glands on backside of connective.—23, 25. Transverse sections of anther glands of *Memecylon caeruleum* and *Mouriri nervosa*.—26, 27. SEMs of anthers of *Pternandra echinata* and *P. caerulescens*, showing absence of glands on backside of connective.—28. Longitudinal section of stamen of *Pternandra caerulescens*. Abbreviation: el, anther elaiophore. Scale bars = 0.5 mm in Figures 24, 26, 27, and 28; 0.2 mm in Figures 22, 23; 0.05 mm in Figure 25.

Such slits are, in fact, reported in some species not known to secrete nectar (Renner, this volume). However, an apparent association of these slits with nectar-producing species, their absence in related non-nectariferous species (e.g., *Blakea chlorantha* vs. *B.* sp. nov. and *B. foliacea*), and field observations of nectar droplets formed precisely at these indentations strongly argue for a role in nectar secretion. These structures may form through a deterioration of a small amount of tissue on the inner side of the geniculum, providing an exit pathway for nectar produced by the staminal vascular bundle. Clearly, a systematic survey of the occurrence of these slits throughout the Melastomataceae would be useful in clarifying their role.

Although nectar production has been reported in *Miconia minutiflora* (Mori & Pipoly, 1984; Mori, pers. comm., 1986), Renner (this volume) has questioned whether the fluid observed was truly nectar. From our anatomical examination, *Miconia minutiflora* does not appear capable of secreting nectar from the stamens in the manner of the other confirmed nectar-producers we investigated. If nectar production in this species is reconfirmed, the conspicuous stigma, which is subtended by cytoplasm-rich vascular tissue, should be closely examined for a possible secretory role. Stigmatic nectar secretion is rare within the angiosperms but occurs in Asclepiadaceae and Araceae (Fahn, 1979).

EVOLUTION OF FLORAL NECTARIES IN MELASTOMATACEAE

Nectaries generally consist of an epidermis subtended by specialized parenchyma cells (Esau, 1977;

Fahn, 1979). The phloem-based nectaries we have found in Melastomataceae, which have no structurally differentiated parenchyma, are a rather extreme deviation from this typical structure. The nonstructural androecial nectaries found in Melastomataceae are particularly anomalous in Myrtales, where, of the 14 families currently included in the order (Dahlgren & Thorne, 1984), only Melastomataceae, Memecylaceae, and Rhynchocalycaceae lack densely staining structural nectaries. Eyde (1981) has discussed evolutionary shifts in the location of floral nectaries in flowers of various myrtalean families and concluded that the ancestral site of nectar secretion for Myrtales, as for many other dicots, is the junction between the gynoecium and the floral tube or, in tubeless flowers, the junction with the androecium. From this ancestral position, nectaries evolutionarily have migrated onto the floral tube, or even onto the androecium in some tubeless species of *Lopezia* and *Epilobium* of the Onagraceae (Eyde & Morgan, 1973; Eyde, 1981). Androecial nectaries are also found in other groups, including virtually all members of the Caryophyllales (Zandonella, 1977). However, the androecial nectaries in these other families are more typical differentiated structures and thus not comparable to the nonstructural androecial nectaries of Melastomataceae, which are certainly unique within the Myrtales and perhaps among angiosperms as a whole.

Given the ancestral myrtalean nectary type and position proposed by Eyde (1981), it seems clear that structural nectaries were lost in the evolutionary lineage ancestral to Melastomataceae and Memecylaceae. Such nectaries appear to have been lost independently in the lineage leading to Rhynchocalycaceae (a monotypic family consisting only of the South African *Rhynchocalyx lawsonioides* Oliver), since on many other grounds this family is more closely related to other members of the Myrtales than to Melastomataceae (Tobe & Raven, 1984).

Pollinator interactions appear to have played a key role in both the ancestral loss and subsequent re-evolution of nectaries within the Melastomataceae. Melastomataceae are, on the whole, a family uniquely suited for bee pollination. The distinctive poricidally dehiscent anthers are directly related to vibratile extraction of pollen by bees, a phenomenon known as buzz pollination. Bees foraging for pollen in this manner rarely forage simultaneously for nectar, and then only to mix it with the pollen to improve the pollen's handling properties (Buchmann, 1983). Although poricidal anthers are found in numerous angiosperms (for review see Buchmann, 1983), few plant families are so completely characterized by this feature as Melastomataceae. Given the widespread distribution of poricidal anthers within all lineages of Melastomataceae, this feature appears to be the ancestral condition for the family. Thus, if buzz pollination became established in the lineage ancestral to Melastomataceae, there would be little or no selective advantage in maintaining energy-expensive nectaries. By attracting undesirable and potentially destructive floral visitors, nectaries may even have been selected against in protomelastomes.

Nectaries appear to have re-evolved independently in several distinct lineages within the family, most of which share certain ecological and reproductive traits. Cruden (1972) has pointed out the potential reproductive advantage ensuing from a shift from bee to bird pollination in wet-tropical montane ecosystems. Similarly, Heinrich & Raven (1972) have noted the increased energy reward necessary to attract pollinators operating at higher elevations and to support vertebrate rather than invertebrate pollinators. Nectar, composed principally of carbohydrates, is a much richer energy source than pollen and is almost invariably the floral reward used to attract vertebrate pollinators. Not surprisingly, most confirmed nectar-producing Melastomataceae (species of *Blakea*, *Brachyotum*, *Chalybea*, *Huilaea*, and *Tibouchina*) occur at high or relatively high elevations, and are known or presumed to be pollinated by vertebrates (Table 2).

According to traditional and recent classification systems for the family (Cogniaux, 1891; van Vliet et al., 1981; Wurdack, 1980), confirmed nectar-producing Melastomataceae are found in at least four different tribes: Blakeae, Dissochaeteae, Miconieae, and Tibouchineae (see Table 1). The phylogenetic relationships among these tribes are not yet resolved, but they undoubtedly do not form a monophyletic lineage within the family. In addition, the majority of genera in these four tribes are not known to produce nectar. Except for the lowland species of *Miconia* discussed above, most of the nectar-producing taxa can be viewed as relatively derived within their respective tribes in terms of pollination systems and ecological/altitudinal preferences. With regard to the latter, the Central and northwestern South American montane terrains that are inhabited by many of these species (and, if the above interpretation is correct, may have provided the ecological impetus for the development of nectar rewards) are generally more recent (Zeil, 1979)

than the origin of the Melastomataceae, fossils of which are known from as early as Eocene times (Hickey, 1977).

Two hypotheses can be advanced to account for the unusual systematic distribution of nectaries within the family. The first is that such nectaries are the basal condition in Melastomataceae and have been lost in the vast majority of species. Given the structural nectaries present in other families of Myrtales and the rather specialized morphological state of most of the nectariferous species, however, such an interpretation is untenable. Renner (this volume) advocates a modified version of this hypothesis, suggesting that "the capacity for developing nectaries is basic in the Melastomataceae but suppressed in most modern members." This supposition seems equally difficult to accept. Rather, we propose a second hypothesis, which is that nectaries have evolved independently a number of times within the family and developmentally have followed the easiest course available. Two lines of evidence point to this. First, three different nectary types have developed within the family, each involving different floral organs (stamens, pistil, petals). Although rare within angiosperms, the most common melastome nectaries, nonstructural androecial nectaries, involve very little modification of existing structures and thus appear to be an easily developed solution to producing nectar. It is difficult, however, to reconcile this view of the ease of developing such nectaries with the relative rarity of nonstructural androecial nectaries in the angiosperms as a whole.

SYSTEMATIC IMPLICATIONS OF NECTARY ANATOMY FOR MEMECYLACEAE

Memecylaceae traditionally have been included in Melastomataceae as a tribe or subfamily (e.g., Cogniaux, 1891; Morley, 1976). Based on floral nectary characters, Memecylaceae agree with Melastomataceae in completely lacking densely staining structural nectaries. The term "disc" has sometimes been used to describe certain structures within the flowers of *Memecylon* (see Bremer, 1983). Given the complete lack of nectariferous tissue, this term should, however, be avoided. As previously discussed, loss of structural nectaries seems to be a feature ancestral for Melastomataceae, and this is probably also the case for Memecylaceae. We regard loss of structural nectaries as a synapomorphy uniting these two families.

Memecylaceae have generally been circumscribed to include the Old World *Memecylon* and the New World *Mouriri* and *Votomita*, all containing anther connective glands. Based on observations of *Mouriri myrtilloides* (Sw.) Poir, Buchmann & Buchmann (1981) suggested that the connective glands of *Memecylaceae* are elaiophores that secrete lipids for nutritional use by pollinating bees, primarily in larval provisioning. Although the secretion is lipid rich, its chemical complexity and the presence of components seemingly toxic to insects have led others to be cautious about this interpretation (Renner, this volume; Simpson & Neff, 1981).

Morley (1976) considered these distinctive but little-understood connective glands to be one of the most characteristic features of the "Memecyleae" (= Memecylaceae), even though they are occasionally lost, as in *Mouriri exadenia* Morley. Whatever its taxonomic rank, the group is now generally considered to include additional genera, among them *Pternandra*, which lacks connective glands (Dahlgren & Thorne, 1984). The present study reconfirms this observation: all examined species of *Memecylon* and *Mouriri* have anther glands on the backside of the connective, whereas all examined species of *Pternandra* lack them. Therefore, even if *Pternandra* is aligned with *Memecylon*, *Mouriri*, and *Votomita* at the familial level, evolution of the anther glands appears restricted to the lineage including the three last-mentioned genera. Available evidence from staminal anatomy does not resolve the correct familial placement of *Pternandra* but does suggest that if included in Memecylaceae, it should be regarded as the sister group to the rest of the family. This is generally the approach taken by van Vliet et al. (1981) in placing *Pternandra* in its own tribe Pternandreae of their "Memecyloideae" (= Memecylaceae).

A SYSTEMATIC REVISION OF *FUCHSIA* SECT. *QUELUSIA* (ONAGRACEAE)[1]

Paul E. Berry[2]

Abstract

Fuchsia sect. *Quelusia* consists of nine closely related species, eight from southeastern Brazil and one from southern Chile and Argentina. This treatment recognizes *F. alpestris* and *F. glazioviana* as separate from *F. regia* and describes two new species from southern Brazil, *F. brevilobis* and *F. hatschbachii*. The section is defined by its shrubby-lianoid habit, opposite-whorled leaves, and distinctive floral pattern associated with hummingbird pollination. It is one of only two entirely polyploid sections in the genus. Unique characters of the section include the large, violet, convolute petals, strongly exserted stamens, and partially connate sepals that are longer than the floral tubes. All nine species occupy cool forest habitats that are remnants of the widespread Tertiary temperate forests of the Southern Hemisphere. With the Old World sect. *Skinnera* as the sister group of all the American species of *Fuchsia*, sect. *Quelusia* represents an early offshoot of the ancestral South American fuchsias, distinct from the tropical Andean and Central American sections in its polyploidy and derived, 3-porate pollen. The nearest relative and sister species of sect. *Quelusia* is *F. lycioides*, a specialized xerophyte and the sole member of sect. *Kierschlegeria*, which occurs in central Chile just north of the range of *F. magellanica*. The Andean and Brazilian populations of sect. *Quelusia* probably became isolated in the late Tertiary, when the austral temperate forests were broken up by increasing aridity to the east of the Andes, as these were strongly uplifted. While *F. magellanica* has not differentiated substantially throughout its range in the southern Andes, sect. *Quelusia* has radiated extensively in the subtropical mountains of southern Brazil, where five of the eight species are restricted to high, isolated mountain peaks. *Fuchsia regia*, on the other hand, is widespread at lower altitudes throughout the planalto and coastal mountains of southeastern Brazil; it is differentiated into three mostly allopatric but intergrading series of populations which are treated here as subspecies. Two of these subspecies are newly described, *F. regia* subsp. *reitzii* and *F. regia* subsp. *serrae*. *Fuchsia regia* is the only species now found to occur sympatrically with other members of the section, and it forms natural hybrids with at least five different species. The only naturally occurring octoploid populations in the genus occur in *F. regia* and appear to be recently derived.

Fuchsia is a distinctive genus of Onagraceae with close to 105 species belonging to ten sections (Berry, 1982; Berry et al., 1988). The genus consists mostly of mesic shrubs confined to cool, moist habitats, with nearly ¾ of the species concentrated in the tropical Andes. The remaining species occur in Mexico and Central America, Hispaniola, southeastern Brazil, the southern Andes, New Zealand, and Tahiti.

In recent years, *Fuchsia* has been the subject of a series of studies designed to refine the taxonomy and to improve our understanding of the evolutionary relationships within the group. A comprehensive analysis of leaf flavonoids (Averett et al., 1986) confirmed the distinctiveness of the New Zealand species of the widely disjunct sect. *Skinnera* from their American congeners. Studies of pollen morphology and ultrastructure in a broad

[1] This study was made possible by financial support provided by the American Philosophical Society, the Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICIT, Venezuela), the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq, Brazil), and the U.S. National Science Foundation through grants to Peter H. Raven. I thank Peter Raven especially for constant support and interest in this project, and Peter Hoch for assistance throughout the preparation of this paper. T. P. Ramamoorthy was an important collaborator in the initial stages of the study. Haroldo Cavalcante de Lima, Daniel Falkenberg, and Gert Hatschbach were gracious hosts and invaluable field guides in Brazil. José Badini, José Fernando Baumgratz, Lois Brako, Rejan Guedes, Luiz Gonzaga, Roberto Klein, Teresinha Silva Oliveira, Solange Vasconcellos de Pessoa, and Raulino Reitz also provided field assistance. Valuable comments on an earlier version of this paper were provided by D. Falkenberg, P. Raven, and J. O. Wright. The staff of the Jardim Botânico do Rio de Janeiro kindly allowed me to use their institution as a base while in Brazil. Illustrations were prepared by Eduardo Pérez, Unidad de Medios Audiovisuales, Universidad Simón Bolívar, in Caracas, Venezuela. I thank the curators of the following herbaria for providing access to materials: A, B, BAA, BAB, BH, BHCB, BHMH, BM, BR, CAS, CGE, CONC, CORD, DS, F, FLOR, G, GH, HB, HBR, HIP, ICN, K, LE, LG, LIL, LP, LY, M, MA, MBM, MICH, MO, NA, NY, O, OUPR, OXF, P, PACA, PEL, POM, R, RB, RSA, S, SGO, SI, SP, SPF, TCD, TEX, U, UC, UEC, US, VALD, W, and Z.

Ann. Missouri Bot. Gard. 76: 532–584. 1989.

array of species have helped to define sectional limits by detecting consistent differences in viscin thread types, aperture number, and grain size (Skvarla et al., 1976, 1978; Nowicke et al., 1984; Praglowski et al., 1983). Systematic revisions for seven of the ten sections in the genus have been completed, based on broad cytological surveys, a thorough review of the major collections of herbarium specimens, and extensive field examination of natural populations (Breedlove, 1969; Berry, 1982, 1985; Breedlove et al., 1982; Berry et al., 1988). The present study uses the same methodology to produce a revision of the species of sect. *Quelusia*, a group centered in southeastern Brazil and forming the largest section outside of the tropical Andes.

A better understanding of the systematics of sect. *Quelusia* is particularly desirable, as the species form a closely related, yet unspecialized group that may have retained many of the primitive characters of the genus. Biogeographically, the section is confined to ancient forest areas in the southern Andes and in southeastern Brazil that show clear austral-Antarctic affinities. Ultimately, this may have been the source area from which other sections differentiated and spread both to Australasia, when more or less direct overland connections were possible across Antarctica until the mid-Tertiary, and to Central America, where several small sections presently occur.

Horticulturally, most of the hundreds of hybrid *Fuchsia* cultivars have been derived primarily from members of sect. *Quelusia* (Reiter, 1944), yet there has been much confusion as to which taxa were involved in the early crosses. Accurate information on the different native species of sect. *Quelusia* can also be expected to stimulate interest in their preservation, cultivation, and use in hybridization for new ornamental cultivars.

In the only recent monograph of *Fuchsia*, Munz (1943) recognized five species in sect. *Quelusia*, together with *Fuchsia hybrida* Hort. ex. Vilm., a name used to encompass most of the common garden hybrids. *Fuchsia magellanica* and *F. regia* included three and four varieties, respectively; these species have the broadest geographical distributions in the genus and also show complex patterns of morphological variation. In this study, *Fuchsia magellanica* is treated as a single, cytologically uniform, polymorphic species with no clear geographical pattern of differentiation. *Fuchsia regia*, on the other hand, has tetraploid and octoploid populations, with geographically differentiated variants that are treated here as comprising three intergrading subspecies. Both *F. alpestris* and *F. glazioviana* are reinstated as distinct species, and two previously unrecognized species are described, *F. brevilobis* and *F. hatschbachii*. As herein delimited, sect. *Quelusia* consists of 11 taxa, with nine different species.

Habitat and Distribution

Fuchsia sect. *Quelusia* is an entirely Southern Hemisphere group of species, with a latitudinal range extending from 18°S to 55°S. It occurs in South America in two large but widely disjunct areas: the southern, temperate Andes of Chile and Argentina, and the coastal mountains and high plains of southeastern Brazil (Fig. 1).

The only species occurring in the southern Andes is *F. magellanica*, which is characteristic of the wet, temperate, Valdivian forests that are centered in the Región de Los Lagos of Chile. These forests are considered to be relicts of an ancient vegetation type that includes many taxa of Australasian affinity, such as *Nothofagus*, *Drimys*, *Podocarpus*, and *Araucaria* (Rambo, 1951; Hueck, 1972; Lötschert, 1981). *Fuchsia magellanica* also extends farther north into drier areas in Chile, where it occurs in moist microhabitats as far north as Santiago and Valparaíso, and then southward to the subantarctic scrub forests of Tierra del Fuego. Throughout its range, *F. magellanica* occurs as low as sea level, but only at its northernmost range does it reach its upper altitudinal limit of 1,750 m. Seasonality increases southwards, so that in Tierra del Fuego, flowering is restricted to the summer months of December to March, and plants are strongly deciduous in the freezing winter months.

The other eight species of the section all occur in the highlands of southeastern Brazil. A single species, *F. regia*, is widespread and covers the entire range of the section in Brazil, from 18°20′S to 29°30′S. The remaining species have much more restricted distributions, several occurring on a single mountain range.

Fuchsia regia consists of three largely allopatric subspecies. Subspecies *serrae* occurs mainly in dense cloud forests at the crests and on the seaward-facing escarpments of the coastal mountains from Rio Grande do Sul to northern São Paulo state, at elevations of 500–1,450 m. In Santa Catarina, however, it is also found in enclaves of montane vegetation on the summits of the isolated "morros" that emerge just 100 to 300 m above the Atlantic lowland forest in the Itajaí Valley (Klein, 1978). It has also been found at sea level in restinga forests near the Santa Catarina–Rio Grande do Sul border,

where Reitz (1961) found a number of other plants typical of the high inland serras.

Fuchsia regia subsp. *reitzii* is restricted to thickets and low forest on the drier planalto, or southern highlands, that occupies much of the interior of Paraná, Santa Catarina, and Rio Grande do Sul. It occurs at altitudes between 900 and 1,700 m in areas subject to strong winter frosts (Klein, 1984). The range of subsp. *reitzii* in this area coincides quite closely with *Araucaria angustifolia*, the dominant element of the planalto forests (Hueck, 1953). In Rio Grande do Sul and southern Santa Catarina, the planalto ends abruptly to the east at the "Aparados" or "Taimbés," sheer cliffs that drop down hundreds of meters to the Atlantic coastal plains. At these sites, subsp. *reitzii* reaches its eastern limit, growing sympatrically along a narrow band with the westernmost populations of subsp. *serrae*.

Fuchsia regia subsp. *regia* occurs further north in a series of separate mountain systems, from northern São Paulo to Rio de Janeiro, Minas Gerais, and Espírito Santo. It grows in cloud forests beginning at 1,000 m and reaches open campos above treeline as high as 2,400 m on Mt. Itatiaia.

Several species are restricted to high altitudes and are known from just one area. *Fuchsia bracelinae* grows only between 2,300 and 2,850 m, above treeline in the "campos de altitude" of a few peaks of the Serra do Caparaó. This is the highest mountain range of southern Brazil, situated along the Minas Gerais–Espírito Santo border. Similarly, *F. campos-portoi* occurs only in campos around Mt. Itatiaia, in the Serra da Mantiqueira, between 2,100 and 2,550 m. *Fuchsia coccinea* occurs naturally only at the summit of four of the highest mountains in Minas Gerais, between 1,400 and 2,000 m.

Two species are endemic to several of the high, granitic "morros" characteristic of the Serra do Mar in Rio de Janeiro state. *Fuchsia alpestris* grows among bushes at the base of granitic outcrops in the Serra dos Orgãos and around Santa Maria Madalena. *Fuchsia glazioviana* is found as high as 2,100 m in open campo vegetation on morros around Nova Friburgo and Santa Maria Madalena. It also descends into cloud forest as low as 1,500 m on the same mountains.

Two newly described species from Paraná and southern São Paulo states have broader ranges. *Fuchsia brevilobis* occurs in forests of low, inland mountain ranges at 600–900 m, but on the eastern slopes of the Serra do Mar in Paraná, it is found from 400 m to sea level. *Fuchsia hatschbachii* occurs further inland in Paraná, in drier forests than the coastal mountains, and is apparently restricted to limestone and sandstone outcrops between 950 and 1,150 m.

Reproductive Biology

The members of sect. *Quelusia* all conform to a very similar pattern of floral biology. The flowers are hermaphroditic and self-compatible, as well as protogynous and herkogamous. Consequently, the genus has been characterized as "modally outcrossing" (Raven, 1979a). Blossoms are always pendent, with the stigma exserted well below the anthers, a prime example of "approach herkogamy" (Webb & Lloyd, 1986), where the stigma is contacted as the visitor enters the flower prior to picking up pollen. Protogyny is incomplete, however, because the anthers begin to dehisce within a day after anthesis, while the stigmas remain receptive from the onset of anthesis until flower senescence several days later. Despite the presence of these outcrossing mechanisms, geitonogamous pollen transfer may still lead to effective selfing. Automatic selfing can also occur, since pollen usually hangs down in clumps joined by viscin threads, which are able to contact the stigmatic surface before the flower senesces.

The flowers of sect. *Quelusia* are highly specialized for pollination by hummingbirds. Each species has red, odorless, hanging, tubular flowers with copious nectar secreted at the base of the floral tube, all standard features in hummingbird-pollinated plants (Faegri & van der Pijl, 1979). Unlike other bird-pollinated fuchsias, however, the petals are much larger and strongly convolute; they thus act functionally as a prolongation of the floral tube, further restricting the access of insects to the nectary. The deep blue-violet color of the petals of sect. *Quelusia* is unique in the genus, although its significance in pollination is not clearly understood. The abundance of viscin threads in *Fuchsia* is among the most copious in the family and has been considered a probable adaptation to bird pollination (Nowicke et al., 1984).

Hummingbirds are commonly observed visiting the flowers of sect. *Quelusia* throughout its native range, but few published accounts have identified the species of the hummingbird visitors. Curtis (1836) cited an early account by J. Anderson, the botanist on Philip King's voyage to the Magellan Straits, who observed numerous hummingbirds visiting *F. magellanica* around Port Famine, even after days of constant rain and sleet at near-freezing temperatures. Hauman-Merck (1912) reported frequent visits of *Eustephanus galeritus* (Mol.) on

F. magellanica near Corral, in Valdivia, Chile. In Brazil, Ruschi (1982) reported *Colibri serrirostris* (Vieillot) visiting flowers of *F. regia*. A Plovercrest hummingbird, *Stephanoxis lalandi* (Vieillot), was observed visiting *Fuchsia* in the open campos area of Mt. Itatiaia, Rio de Janeiro state by Mitchell (1957), as well as by Ruschi (1982) in Teresópolis at 900 m. Three hummingbird species, *Colibri serrirostris*, *Stephanoxis lalandi*, and *Leucochloris albicollis*, were common around *F. bracelinae* in the Serra do Caparaó, at 2,400 m, during a visit in February 1985 (L. Gonzaga, pers. comm.). It is unlikely that any strong pollinator discrimination exists between the different species of *Fuchsia* in Brazil, since the flowers are very similar in size and overall floral pattern. On both *F. campos-portoi* and *F. brevilobis*, I have seen two different hummingbird species visiting flowers of the same bush in rapid succession, and I also watched an individual hummingbird visit flowers of *F. brevilobis* right after leaving flowers of a neighboring plant of *F. regia* subsp. *serrae*.

Besides hummingbirds, several insect species have also been observed visiting flowers of sect. *Quelusia* in their native habitat. *Apis mellifera* was a common visitor to flowers of *F. coccinea* at Serra da Piedade, Minas Gerais, during our visit in February 1985; it was also observed on *F. campos-portoi* at Mt. Itatiaia in January 1985. Hauman-Merck (1912) described the visits of *Bombus chilensis* to *F. magellanica* in southern Chile, and thought it to be a more important visitor there than hummingbirds. Both of these bee species hang from the anthers to collect pollen and may attempt to reach the nectary at the base of the tube; *Bombus*, especially, is able to make contact with the stigma and acts as an effective pollinator. I also saw a butterfly visiting *F. regia* subsp. *serrae* near Mogi das Cruzes, São Paulo, Brazil; it grasped the stamens attempting to enter the floral tube for nectar and made contact with both the anthers and the stigma in the process. When species of sect. *Quelusia* are cultivated outside their native range in areas where hummingbirds do not occur, such as England, they are frequently visited by honey bees and bumblebees (J. Wright, pers. comm.).

Seed dispersal is probably effected by frugivorous birds, although no direct observations or published reports have been made.

Morphology

Habit and stems. Plants of sect. *Quelusia* are all shrubs or lianas. Stems are usually flexuous and require the support of neighboring vegetation, but low, densely branched shrubs are common in such species as *F. coccinea* and *F. bracelinae*. *Fuchsia regia* can become a large, forest liana, with stems to 20 cm in diameter climbing as high as 15 m into the tree canopy, but it can also be found growing as a compact shrub in open situations. On large, climbing plants of *F. regia* and *F. alpestris*, it is common to find hanging branches several meters long. Short, divaricating side shoots are typical of young plants of *F. regia* subsp. *serrae*.

Vegetative reproduction occurs in most taxa through stem-layering, especially when long, flexuous stems lay over ground litter. *Fuchsia bracelinae* and *F. coccinea* reproduce locally by underground, stoloniferous stems, and some populations of *F. regia* subsp. *serrae* produce aerial roots on shoots well above the ground, as described by Lindley (1841) for *F. radicans*.

Leaves. Phyllotaxis in sect. *Quelusia* is opposite or whorled. The most common condition in the section is ternate leaves, but individual plants often combine leaves in pairs, threes, and fours on different shoots. Exceptions are *F. alpestris*, almost always with opposite leaves, and *F. regia* subsp. *reitzii*, with leaves all in whorls of 3, 4, or 5. *Fuchsia glazioviana* has unusually short internodes, just 3–12 mm long, with the leaves densely packed on the stems.

The texture of the leaves of most species is membranous, but *F. regia* subsp. *serrae* has coriaceous leaves, and those of *F. regia* subsp. *regia* are mostly subcoriaceous. Leaf surface is a useful character in some taxa; it is smooth and lustrous in *F. regia* subsp. *serrae*, with a dark green color above and a paler tone below. Leaf surfaces of *Fuchsia glazioviana* and *F. hatschbachii* are similar, but the surface is less brilliant. Impressed leaf veins are especially characteristic of *F. bracelinae*, and to a lesser degree in *F. brevilobis*. Secondary venation in leaves of *F. campos-portoi* can be almost imperceptible, while in *F. regia* subsp. *reitzii* a conspicuous tertiary venation is usually evident.

Leaf size and shape vary considerably within taxa, but some differences can be readily distinguished. The leaves of *Fuchsia glazioviana*, *F. bracelinae*, and *F. campos-portoi* are small, mostly less than 4 cm long, and very narrow in *F. campos-portoi*. The largest leaves occur in *F. alpestris* and *F. regia* subsp. *regia* and are mostly 6–14 cm long. Ovate leaves with cordate bases are diagnostic of *F. coccinea*.

Leaf margins are characteristically gland-denticulate, but in *F. campos-portoi* and *F. regia*

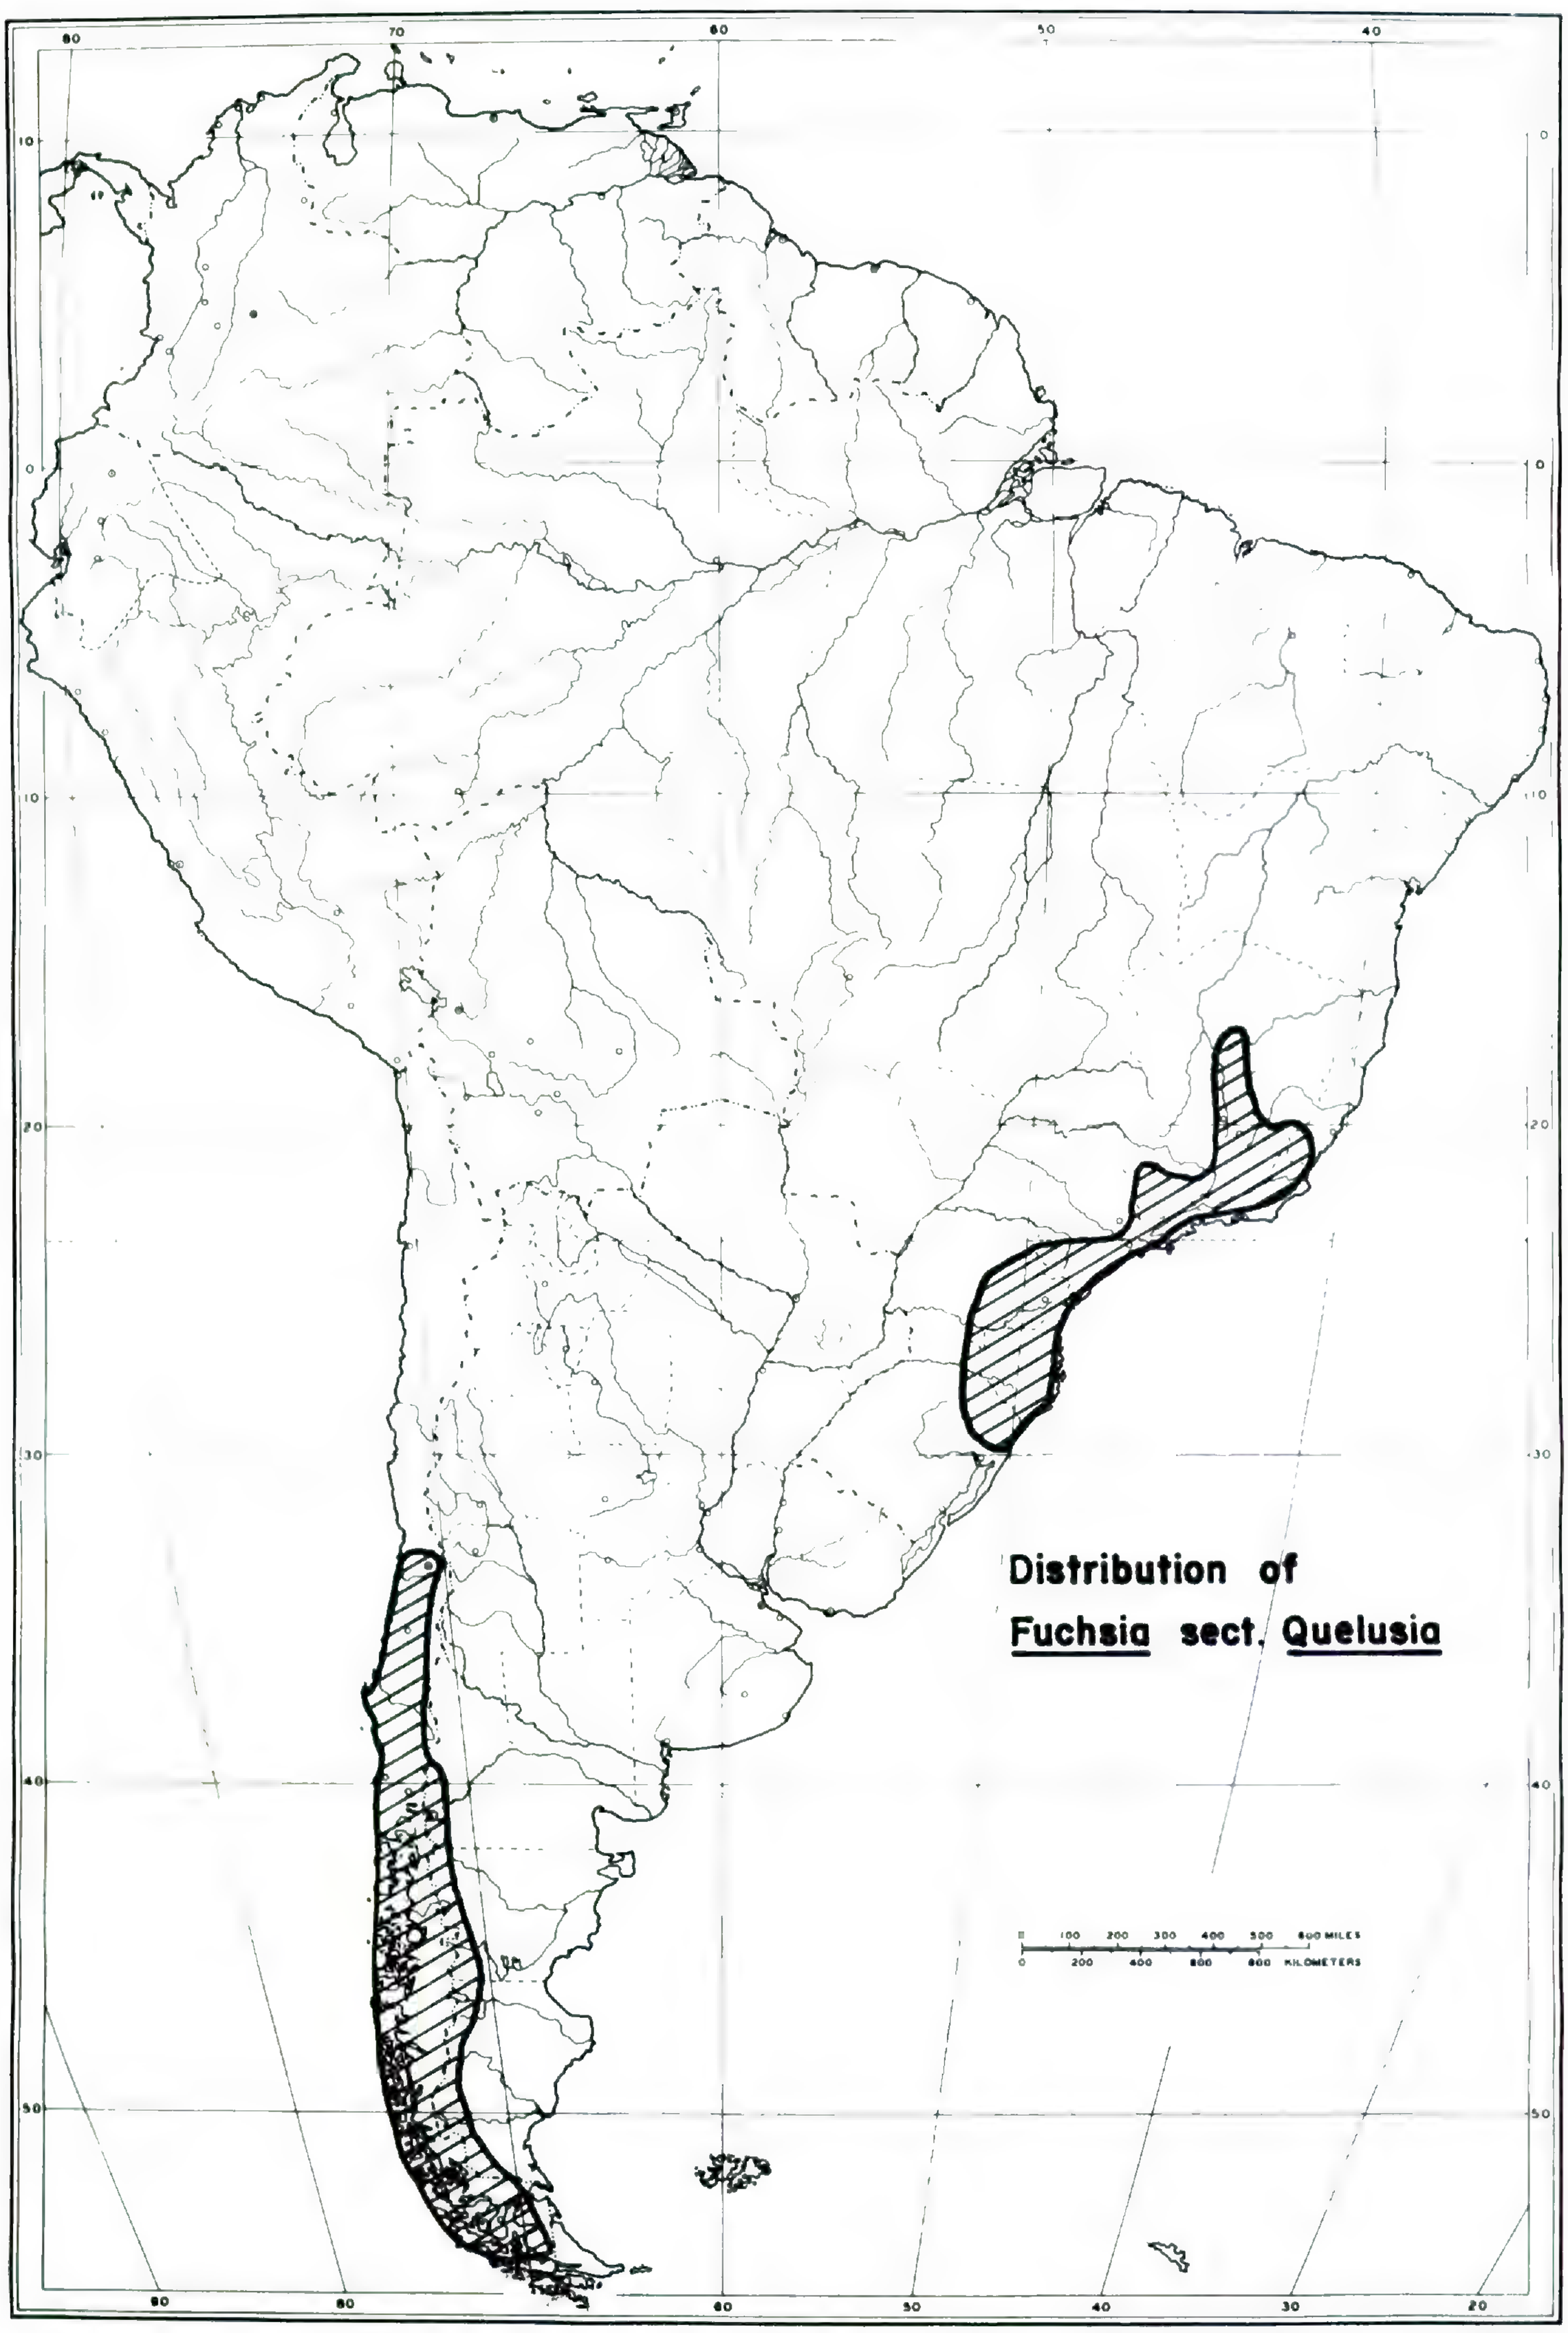

FIGURE 1. Native distribution of *Fuchsia* sect. *Quelusia*.

subsp. *reitzii* they are conspicuously gland-serrulate, with the teeth angled towards the leaf apex. *Fuchsia magellanica* has mostly serrulate margins, but they are sometimes crenate, with shallow lobes between the teeth.

Petiole length is useful in discriminating taxa in sect. *Quelusia*. *Fuchsia coccinea* and *F. bracelinae* have nearly sessile leaves, with petioles 1–3 mm long, while they exceed 10 mm in *F. regia* subsp. *regia* and *F. regia* subsp. *serrae*. Often the proportion of the petiole to the blade length is very informative: high (> 1 : 4) in *F. regia* and *F. magellanica*, and low (1 : 8 <) in *F. hatschbachii* and *F. alpestris*. Petioles are stout and over 1 mm thick in *F. alpestris*, *F. coccinea*, *F. regia* subsp. *serrae*, and *F. regia* subsp. *regia*; they are slender in *F. magellanica*.

Stipules in all but one taxon are small, lanceolate, and deciduous. *Fuchsia regia* subsp. *serrae* is unique, with prominent, persistent stipules that are thick and recurved, usually fused in pairs between adjacent leaves, and give a characteristic nodose appearance to the stems.

Flowers. Flowers are all borne singly or rarely in pairs in the axils of young leaves near the branch tips. Rarely more than two or three whorls of leaves bear flowers at the same time on a single stem. The pedicels are pendulous, except in *F. coccinea*, where they are divergent from the stem before hanging down in the distal half.

Section *Quelusia* is the only group in the genus where the sepals are much longer than the floral tube. In addition, the sepals are always connate to varying degrees at their base, which in effect lengthens the tubular portion of the flower. The petals are strongly convolute and form a cone around the stamens and stigma. The nectary consists of a smooth to slightly lobed band ca. 1 mm thick lining the inner, basal portion of the floral tube. A flower from sect. *Quelusia* is illustrated diagrammatically in Figure 2.

The floral tubes of most species are cylindrical-fusiform, but *F. campos-portoi* is distinct with its short, subrhombic tubes. Sepal connation is only 3–6 mm in most taxa. *Fuchsia brevilobis* is exceptional, with sepals connate for 10–16 mm, almost completely concealing the corolla and longer than either the free sepal lobes or the true floral tube. *Fuchsia regia* subsp. *serrae* also has sepals joined for over ⅓ their length; the buds are noticeably four-ridged, and the free lobes sometimes recurve after anthesis.

Fruits. Berries in sect. *Quelusia* are generally oblong-ellipsoid and dark purple to black when ripe. In *F. regia* subsp. *reitzii*, the berries are mostly globose, while in *F. magellanica* they are much more elongate than in the other species. Ovules are biseriate in each locule and number between 60 and 120 per fruit.

Cytology and Palynology

Cytology. Concurrently with this revision, Hoshino & Berry (1989) made an extensive cytological survey of all 11 taxa of sect. *Quelusia*, examining 103 individuals from natural populations and 11 cultivated plants. Their results showed the section to be entirely polyploid, predominantly tetraploid ($n = 2x = 22$), but with octoploidy ($n = 4x = 44$) found in two species. All other sections in the genus, except for the tetraploid, monotypic sect. *Kierschlegeria*, are entirely or mostly diploid ($n = x = 11$).

Tetraploidy was found in all specimens examined of six Brazilian species and in the more than 40 populations that were studied from the widespread *F. magellanica* of the southern Andes (see Hoshino & Berry, 1989, Table 1). Normal bivalent formation was observed in all of these collections.

Octoploidy was limited to the three subspecies of *F. regia* and a single cultivated individual of *F. alpestris*. *Fuchsia regia* subsp. *reitzii* and *F. regia* subsp. *serrae* were consistently octoploid, but tetraploid individuals were also found in *F. alpestris* and *F. regia* subsp. *regia*. In all octoploids examined, varying numbers of quadrivalents were present at meiotic Metaphase I and Anaphase I. Although tetraploid and octoploid plants occurred sympatrically in several localities, no hexaploid individuals were detected. The chromosome numbers of the individuals examined by Hoshino & Berry are indicated in this paper under the specimen citations of the respective taxa.

Palynology. Pollen grains of *Fuchsia* have distinctive, onagraceous features such as viscin threads, paracrystalline-spongy ektexine, protruding apertures, and a solid endexine. The genus is unique, however, in possessing predominantly two-aperturate, bilaterally symmetrical pollen grains. Radially symmetrical, three-aperturate grains also occur in the genus but are confined to polyploid species and are clearly derived from two-aperturate ancestors, a result of the increased cell volume of polyploid cells. Most sections of the genus can be distinguished by a combination of aperture number, viscin thread ultrastructure, and type of exine sculpture elements. Detailed pollen descriptions of the different sections are provided in Praglowski et al. (1983) and Nowicke et al. (1984).

The members of sect. *Quelusia* have radially symmetrical and three-aperturate pollen grains, a condition consistent with the polyploidy found in all species of the section. Viscin threads are segmented-beaded, and the exine has globular sculpture elements. Praglowski et al. (1983) reported a size range of 33–60 μm for P (polar axis length) and 59–85 μm for E (equatorial axis) for the seven taxa they examined. Rare four-aperturate grains have been found in *F. coccinea* and *F. regia*; occasional two-aperturate grains were also found in *F. magellanica* and were considered to be reversions to the ancestral condition of the genus (Praglowski et al., 1983; Nowicke et al., 1984). Octoploid individuals of *F. regia* cannot be distinguished from tetraploids by differences in pollen morphology, although octoploid pollen grains may be significantly larger (Hoshino, pers. comm.).

The only other section of *Fuchsia* characterized by three-aperturate pollen is the monotypic sect. *Kierschlegeria* (*F. lycioides*). Its pollen can be distinguished from that of sect. *Quelusia*, however, by the smooth viscin threads with elongated sculpture elements (Nowicke et al., 1984).

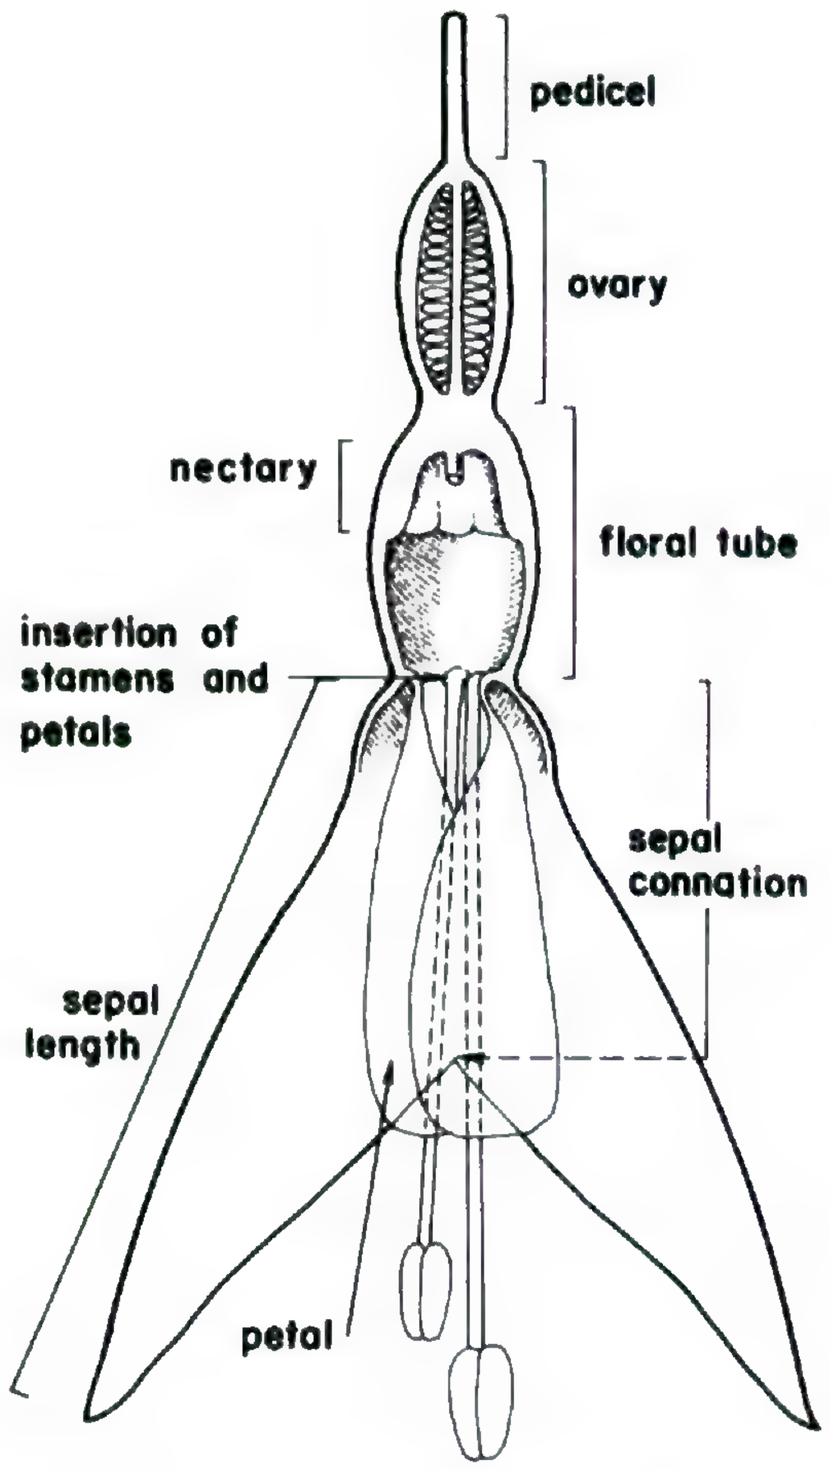

FIGURE 2. Schematic longitudinal section of a flower from *Fuchsia* sect. *Quelusia*, with terminology used in the species descriptions.

FLAVONOID COMPOUNDS

Because of the ornamental appeal of *Fuchsia*, several studies have examined the role of anthocyanins in the different flower colors in the genus (Harborne, 1963; Yazaki & Hayashi, 1967; Nozzolillo, 1970; Yazaki, 1976; Crowden et al., 1977). Flower colors are determined almost entirely by the 3-glucosides and 3,5-diglucosides of all six common anthocyanins. Red coloration in the sepals and floral tube is due mostly to cyanidin and peonidin pigments, whereas the characteristic blue-violet color of the petals of all members of sect. *Quelusia* is due to the dominance of malvidin derivatives, with peonidin in much lesser concentrations (Nozzolillo, 1970; Yazaki, 1976; Crowden et al., 1977). Yazaki (1976) indicated that the intense blue-violet color of some cultivars is due to the simultaneous presence of other co-pigments in the cell, particularly quercetin glycosides. In some cultivars, the petals change color from blue-violet to purple-red with age; Yazaki (1976) has shown this to be due to the combined effect of the flavonoid co-pigments, together with a decrease in the pH of the cell sap brought about by the accumulation of organic acids.

Averett et al. (1986) carried out a comprehensive survey of the foliar flavonoids in 80 taxa of *Fuchsia* and reported the flavonoid profiles of four taxa belonging to sect. *Quelusia*. Current taxonomic changes in the section, however, have modified these results, and a revision is presented in Table 1. Based on the same samples examined by Averett et al. (1986), two additional taxa are now included, *F. brevilobis* and *F. regia* subsp. *serrae*. From these changes, it is apparent that it is *F. brevilobis*, not *F. regia*, that has a distinctive flavonol diglucoside. *Fuchsia magellanica* remains the only species in the section known to possess flavones (compounds 12 and 15), which could be used as excellent markers for detection of the parentage of this species in cultivars of uncertain origin, although flavones might not be expressed in all *F. magellanica* hybrids. Otherwise, the remaining flavonol monoglucosides are all of common occurrence in other taxa of the genus.

NATURAL HYBRIDIZATION

Because of the restricted distributions of most of the Brazilian species of *Fuchsia*, there is no range overlap among them, except with the widespread *F. regia*. *Fuchsia regia* occurs sympatrically with five other species, and in each case, morphologically intermediate, putatively hybrid individuals have been detected (Table 2). Populations of *F. regia* subsp. *serrae* also occur together with each of the other subspecies of *F. regia*, forming extensive hybrid swarms in areas of sympatry.

TABLE 1. Foliar flavonoids in species of *Fuchsia* sect. *Quelusia*.[1]

Taxa Examined	Compounds[2]									
	1	2	3	5	6	7	8	9	12	15
F. brevilobis	+		±	+	+			±		
F. campos-portoi	+		+		+	+	+	+		
F. coccinea	+				+	+	+	+		
F. magellanica	+	+	+		+	+	±		+	+
F. regia subsp. *regia*	+	±	+		+	±	+	+		
F. regia subsp. *serrae*	+	±	+		+	±	+	+		

[1] Based on the same samples as reported in Averett et al. (1986); changes in identifications are as follows: *Davidse et al. 10904*, *Hatschbach & Ramamoorthy 42974* (*F. brevilobis*), *Conrad & Dietrich 2055*, *Hatschbach & Ramamoorthy 42976*, *Ramamoorthy & Reitz 1163*, and *Ramamoorthy & Vital 685* (*F. regia* subsp. *serrae*); *Ramamoorthy & Vital 673, 674, 676, 680* (*F. regia* subsp. *regia*).

[2] + = present in all collections sampled, ± = present in some collections but absent in others. Same numerical codes as in Averett et al. (1986): 1 = K-3-O-glu; 2 = K-3-O-gal; 3 = K-3-O-rham; 5 = K-3-O-rham-glu; 6 = Q-3-O-gluc; 7 = Q-3-O-gal; 8 = Q-3-O-rham; 9 = Q-3-O-ara; 12 = A-7-O-glu; 15 = L-7-O-glu. Abbreviations: K = kaempferol, Q = quercetin, A = apigenin, L = luteolin, glu = glucose, gal = galactose, rham = rhamnose, ara = arabinose.

The morphological intermediacy of several characters was the main criterion used in detecting hybrids between different taxa; in most cases, both putative parents were growing sympatrically close by. Details of the different hybrid combinations found are provided in the Appendix.

Natural hybridization among sympatric taxa of sect. *Quelusia* appears to occur readily, as there are no major differences in pollinators, flowering time, or habitat in mixed populations. The only indication that reduced fertility might occur in hybrids was from one artificial cross between a tetraploid individual of *F. regia* subsp. *regia* and an octoploid individual of *F. regia* subsp. *serrae*, where the hexaploid progeny showed low pollen fertility (Hoshino & Berry, 1989). More experimental work is needed on the chromosomal behavior of crosses between tetraploid and octoploid taxa in sect. *Quelusia*.

In most cases, the area where two species overlap is small, and the frequency or abundance of hybrids is low compared with the parental populations. *Fuchsia campos-portoi*, *F. coccinea*, and *F. glazioviana* are all high-altitude species that grow in the open "campos de altitude" at or above treeline. Hybrids between these species and *F. regia* occur where they descend into the upper forest zone, or when *F. regia* extends beyond its normal limit into the open campos. *Fuchsia brevilobis* has the inverse of this pattern, generally occurring at lower altitudes than *F. regia* subsp. *serrae*, with probable hybrids in limited areas where their ranges overlap. *Fuchsia bracelinae* may have grown sympatrically with *F. regia* until the past century, when extensive cutting and burning eliminated the upper forest belt of most of the Serra do Caparaó.

The situation among the subspecies of *F. regia* is notably different. These taxa are much more widespread and overlap more extensively than any of the other species in the section. *Fuchsia regia* subsp. *reitzii* is typical of the planalto region in Rio Grande do Sul and southern Santa Catarina states, but it contacts populations of the more mesic *F. regia* subsp. *serrae* along the easternmost edge of the planalto near the crests of the Serra Geral, producing large, widely variable, intermediate populations. Extensive intergradation between *F. regia* subsp. *regia* and *F. regia* subsp. *serrae* occurs

TABLE 2. Sympatric occurrence and natural hybridization among the native taxa of *Fuchsia* sect. *Quelusia* in Brazil. An X indicates that both sympatry and natural hybridization occur. Abbreviations are of the first three letters of the specific (capitals) or subspecific (lower case) epithets.

Subspecies of *F. regia*									
subsp. *regia*	X	—	—	X	X	X	—		
subsp. *reitzii*	—	—	—	—	—	—	—	—	
subsp. *serrae*	—	—	X	—	—	—	—	X	X
	ALP	BRA	BRE	CAM	COC	GLA	HAT	reg	rei

along the eastern edge of the Serra da Bocaina and the Serra do Mar in northern São Paulo state.

Although *F. regia* is the only species presently found in widespread contact with other species of sect. *Quelusia*, the numerous hybrid combinations detected indicate that interspecific genetic recombination may have been an important mechanism in providing a rich source of novel, adaptive genotypes in the fuchsias of southern Brazil.

Evolution of Section *Quelusia*

Various lines of evidence, including chloroplast DNA restriction fragment analysis (Sytsma & Smith, 1988) and leaf flavonoid analyses (Averett et al., 1986), have suggested the Old World sect. *Skinnera* to be the earliest offshoot of the genus and the sister group of all the American sections of *Fuchsia*. The oldest fossil pollen grains of the genus have been found in New Zealand and Australia from Oligocene and Miocene deposits (Pocknall & Mildenhall, 1984; Berry et al., in prep.). Despite the early divergence of this group, the members of sect. *Skinnera* exhibit several specialized features for the genus, including the derived condition of male sterility, reduced petals, presence of flavone sulphates, and a variety of unusual life forms, such as large trees and procumbent creepers.

The most likely area of origin of *Fuchsia* is South America, where the greatest concentration of species as well as the sections with the most generalized features in the genus occur (Raven, 1979a; Berry, 1982). Whereas the large Andean sections appear to have arisen and radiated during the Neogene uplift of the tropical Andes (Berry, 1982, 1985), the areas now occupied by sect. *Quelusia* have changed little since the mid-Tertiary, when temperate forests were much more widespread in southern South America (Simpson, 1973). With the current Australasian fossil record, it is now apparent that *Fuchsia* formed part of the *Nothofagus* and podocarp-dominated temperate forests that occurred more or less continuously across southern South America, Antarctica, and Australia until at least the late Eocene (Zinmeister, 1987; Truswell, in press). The wet, temperate forests of the southern Andes and the montane forests of southeastern Brazil are now the only remnants of these austral temperate forests in South America, which, like *Fuchsia*, share a large number of disjunct plant groups that also have close relatives in Australasia (Raven, 1979b).

Although there are no fossil records to indicate an early presence of sect. *Quelusia* in South America, the section follows a pattern consistent with other relicts of the southern temperate forests. It is ecologically conservative, with most individuals restricted to moist sites in cool, forest habitats. Morphologically, there is little divergence in the section, with species differentiated by relatively minor variations on a common pattern of floral and vegetative characters. Many of the features of sect. *Quelusia* are unspecialized in the genus, including the axillary, bisexual flowers, well-developed petals, numerous seeds, and segmented-beaded viscin threads. It is possible that some of the primitive characters in sect. *Quelusia* were preserved through the buffering effects on evolutionary divergence caused by paleopolyploidy in the group (Stebbins, 1985; Hoshino & Berry, 1989).

The ancestor of the modern-day species of sect. *Quelusia* was probably tetraploid, with derived, three-porate pollen (Hoshino & Berry, 1989). As such, it could not have given rise directly to the other, mostly diploid, sections of the genus, but rather represents an early offshoot of the ancestral stock of *Fuchsia* in South America. Early on, sect. *Quelusia* developed its own floral syndrome for hummingbird pollination: the relatively short, nectar-holding floral tube; large, attractive sepals; and petal cone and sepal tube that further extend the tubular portion of the blossom.

Section *Kierschlegeria*, containing only *F. lycioides* restricted to the dry coastal scrub of central Chile, is the only other section of *Fuchsia* that is entirely polyploid and has three-porate pollen grains. Because of this similarity and its geographic proximity to *F. magellanica*, Berry (1982) and Raven (1988) postulated that it is related to sect. *Quelusia*. Using chloroplast DNA restriction fragment analysis, Sytsma & Smith (1988) demonstrated that sects. *Quelusia* and *Kierschlegeria* form a distinct lineage from the rest of the genus, defined by three synapomorphies. Furthermore, within this lineage *F. lycioides* could not be distinguished from the two species of sect. *Quelusia* studied, *F. magellanica* and *F. regia*. This evidence of a close relationship is remarkable, since *F. lycioides* has a high number of specialized features, such as functional dioecy, spinose leaf bases, low seed number, smooth viscin threads, small flowers, and summer deciduousness. Evidently, the evolutionary shift of sect. *Kierschlegeria* to a xeric habitat in the southern Andes entailed a large number of morphological changes corresponding to a much smaller degree of genotypic divergence.

Within sect. *Quelusia*, we are faced with the question of why there is just one species in Chile and Argentina, while in Brazil there are eight species

in an area of comparable size. *Fuchsia magellanica* is a classic example of the lack of differentiation that is characteristic of the *Nothofagus* forests of Chile. These habitats presumably have been stable and continuous for long periods of time, providing little opportunity for speciation to occur. Most taxa inhabiting these areas have retained primitive characters for their respective groups (Simpson, 1973). Although the current distribution of *F. magellanica* extends beyond the *Nothofagus* forests, virtually all of the area now occupied by this species south of 44°S latitude was covered by ice during the Pleistocene (Vuilleumier, 1971).

In contrast to the temperate latitudes of Chile and Argentina, the Brazilian members of sect. *Quelusia* are centered in the subtropics. There, *Fuchsia* is limited to the cool, moist habitats of the coastal mountains and the interior planaltos. Most of the cold-adapted taxa of Brazilian fuchsias are vicariant species that are now restricted to just a few high mountain peaks. Allopatric speciation in this group of species was likely enhanced by the joining and subsequent separation of populations caused by the cycles of Pleistocene glacial and interglacial events (Simpson, 1979; Klein, 1984).

Two of the Brazilian species have adapted to warmer, lower-altitude habitats that are more continuous over much of the southeastern part of the country. *Fuchsia regia* extends over the entire range of the section in Brazil and forms a broad taxonomic complex treated here as comprising three subspecies, each adapted to a slightly different set of environmental conditions. This species shows an intermediate stage in the morphological differentiation of populations between the more uniform *F. magellanica* in the southern Andes and the distinct, high-altitude species of Brazil. *Fuchsia regia* overlaps geographically with most of the other species in the section and hybridizes with them whenever they come into contact; these hybrids may constitute an important source of genetic recombination for new adaptive genotypes in the section. It is also the only species in the genus with naturally occurring octoploid populations, which may lead to partial reproductive isolation with the other tetraploid taxa in the section.

Two newly described species from Paraná, Brazil both consist of tetraploid populations that occur within the range of the octoploid subspecies of *F. regia*. The different ploidy levels may afford sufficient reproductive isolation for these species to remain distinct. One of the new species, *Fuchsia hatschbachii*, is the only species in the section that appears to be edaphically specialized, occurring on limestone and sandstone substrates on the eastern edge of the southern planalto. Populations of *F. regia* subsp. *serrae* occur within 15 km of *F. hatschbachii* near Curitiba, Paraná, but the two have never been observed to grow together under natural conditions. The other new species, *Fuchsia brevilobis*, is specialized in its small flowers with elongate sepal tubes, and it has become adapted to lower altitudes than most neighboring populations of *F. regia*.

Overall, the evolutionary scenario of sect. *Quelusia* differs significantly from the two, more speciose, Andean sects. *Fuchsia* and *Hemsleyella*. Those species radiated recently into a broad expanse of new, cool montane habitats that were created with the recent uplift of the tropical Andes (Berry, 1982, 1985). Section *Quelusia*, on the other hand, has occupied a more ancient and stable vegetation type in which disruptive selection may have played less of a role in the divergence of populations.

Cladistic Analysis

This section examines the relationships of the taxa of sect. *Quelusia* and the closely related *F. lycioides* by means of a formal cladistic analysis. The advantages of this approach are that it provides clearly stated hypotheses about evolutionary relationships based on shared, derived character states, and it is based on an objective, repeatable methodology.

The data were analyzed on an ATT 6300 microcomputer by the Wagner parsimony method of the PAUP software package (version 2.4.1., Swofford, 1985), using the branch and bound algorithm (Hendy & Penny, 1982). Character polarity was determined by outgroup comparison (Hennig, 1966; Watrous & Wheeler, 1981), using sect. *Skinnera* as the outgroup. In two characters, however, the character states in sect. *Skinnera* are almost certainly apomorphic in the genus; so in these cases the other genera of Onagraceae were used as the outgroup.

Twenty-two characters were used in the phylogenetic analysis, with the character states listed in the data matrix (Table 3).

Fifteen equally parsimonious trees were produced, each with 29 steps and a consistency index of 0.931. Topologically all the trees are identical, as they represent arbitrary resolutions of a single tetrachotomy that appears in the trees. The unique topology of these trees is presented in Figure 3. According to these results, sects. *Kierschlegeria* and *Quelusia* form a monophyletic group defined by five synapomorphies, but within this clade *F.*

TABLE 3. Data matrix for characters of taxa used in the cladistic analysis of *Fuchsia* sects. *Quelusia* and *Kierschlegeria*. Sect. *Skinnera* is used as the outgroup. Characters 9, 16, and 17 are unordered. A zero represents the plesiomorphic states, and higher numbers represent the apomorphic states. In those characters where no zero appears, the plesiomorphic conditions are uncertain, and the character states were coded as unordered.

lycioides is the sister group to all of sect. *Quelusia*. Section *Quelusia* is well delimited by the presence of four synapomorphies, and *F. lycioides* possesses eight unique, derived character states (autapomorphies). Within sect. *Quelusia*, *F. magellanica* appears as the sister group of all the Brazilian taxa, which are grouped by a single character, loss of flavones. The Brazilian taxa of *Fuchsia* are poorly differentiated by the cladistic analysis, forming a polychotomy with four different lineages. *Fuchsia hatschbachii* is an isolated line in Brazil, differing from *F. magellanica* only by the loss of flavones. The three subspecies of *F. regia* form a separate, mainly octoploid lineage, supporting the monophyly of *F. regia* sensu lato. *Fuchsia glazioviana* and *F. campos-portoi* are sister species within the third lineage. The fourth lineage includes four species, which are divided into two species pairs, the high-altitude *F. bracelinae* and *F. coccinea*, and *F. alpestris* and *F. brevilobis*. Two homoplasies (parallelisms) occur in the cladogram: long-connate sepals in *F. brevilobis* and *F. regia* subsp. *serrae*, and lianoid habit in two species pairs.

The paucity of characters that discriminate between the taxa of sect. *Quelusia* makes the results of the cladistic analysis within the section quite tentative, but it is also a reflection of the very close relationship of the species. The proposed sister-

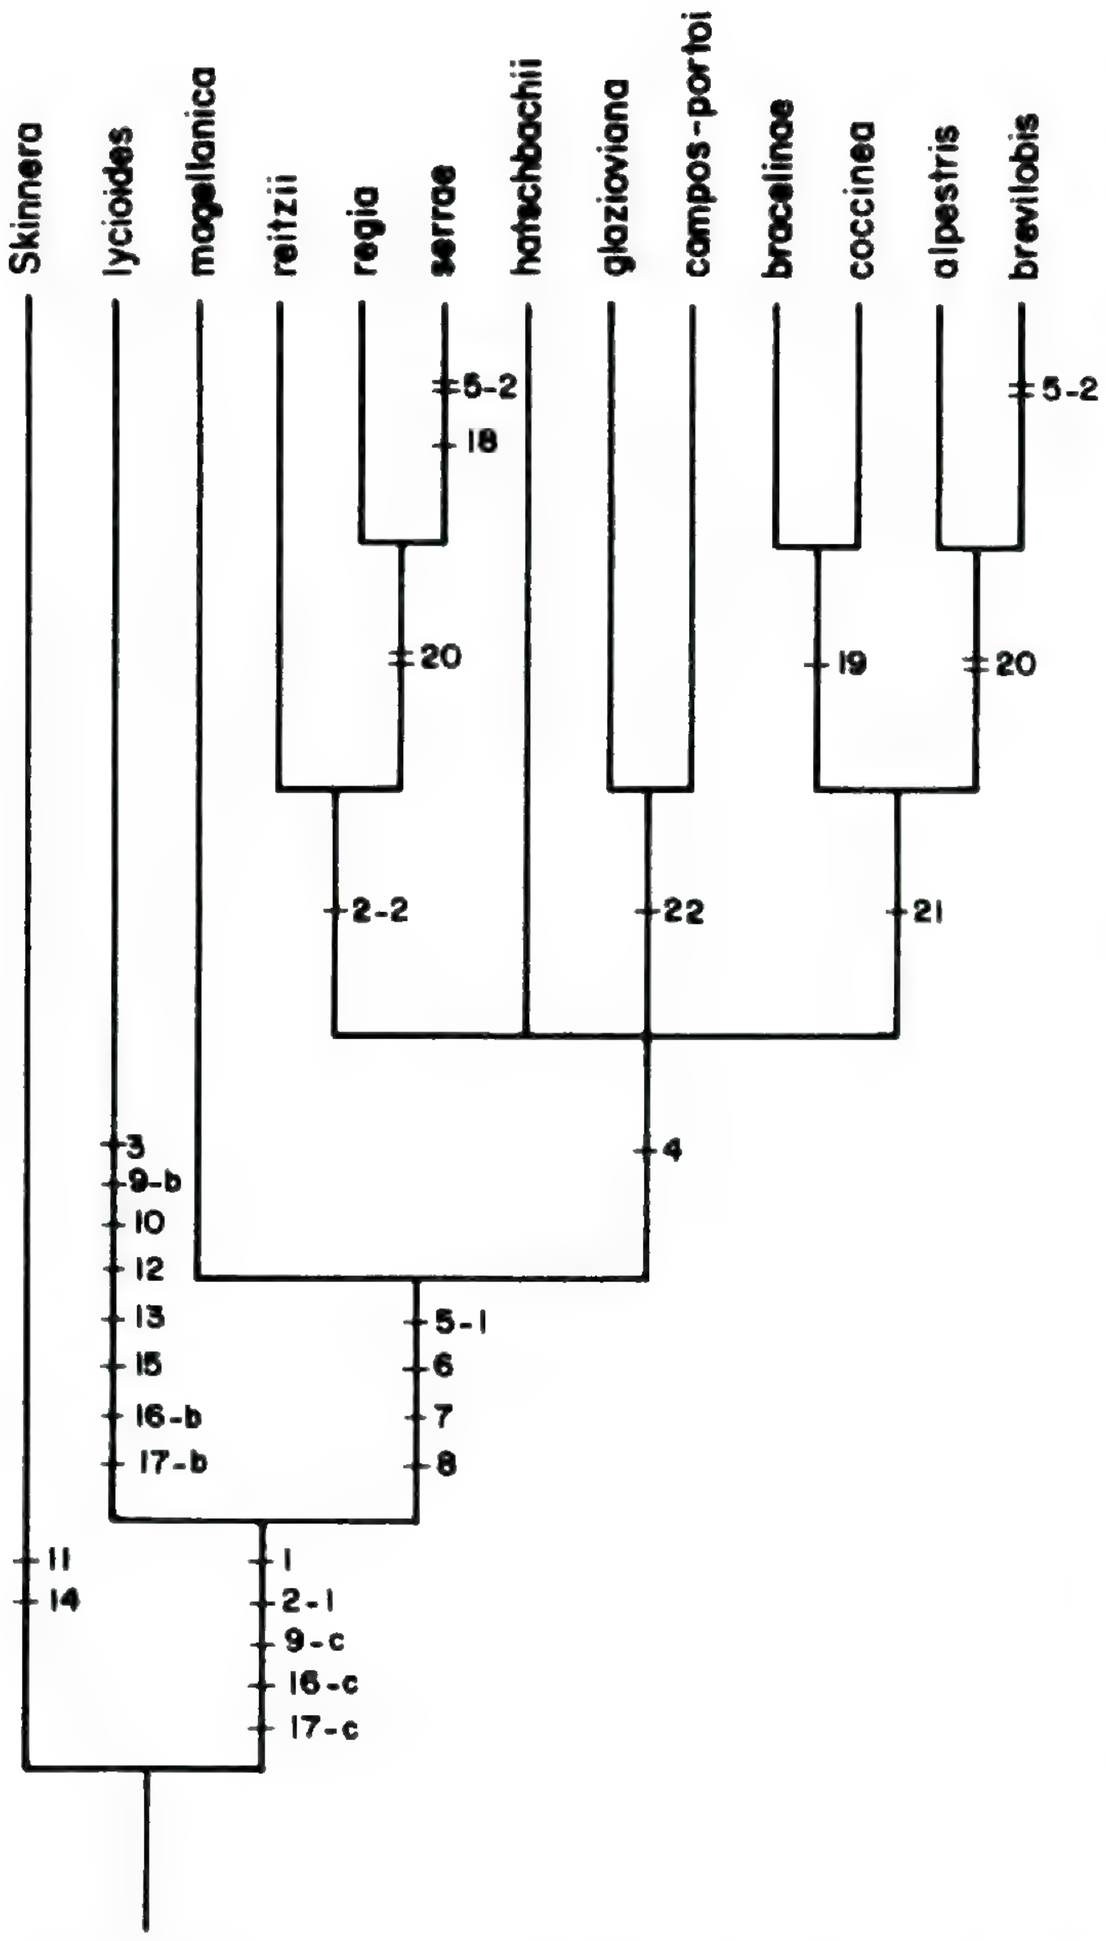

FIGURE 3. Cladogram of *Fuchsia* sects. *Quelusia* and *Kierschlegeria* (*F. lycoides*). Sect. *Skinnera* is used as the outgroup. Double crossbars indicate homoplasies. See Table 3.

group relationship of *F. magellanica* to the Brazilian members of the section is consistent with the biogeography of the group and the evolutionary hypotheses discussed previously, specifically the southern origin of the genus in South America and the secondary radiation of the section in the highlands of southeastern Brazil. According to this hypothesis, the Brazilian taxa differentiated, after their separation from the Andean *F. magellanica*, from an ancestor that had lost flavones. The occurrence of two parallelisms between *F. brevilobis* and *F. regia* subsp. *serrae* is remarkable and may be the result of past hybridization between the two species.

History of Cultivation

Members of sect. *Quelusia* were by far the most important species used in the early stages of fuchsia breeding. For the most part, however, fuchsia breeders in the past century kept few records about the parentage of their introductions. As a result, it is impossible to determine with certainty which species have been involved in the parentage of most of the modern cultivars (Reiter, 1944). Ancestry of sect. *Quelusia* can be assumed in cultivars that share the following exclusive "quelusioid" traits: fairly large, axillary flowers with sepals equal to or longer than the floral tube, and large, violet, rounded, and strongly convolute petals.

Following Reiter (1944), one can distinguish three stages in the history of fuchsia breeding during the past century. First, a variety of species and natural varieties were accumulated in cultivation. Next, these were crossed to select desirable combinations and produce a few, selected strains. This second stage began mostly with crosses between different introductions from sect. *Quelusia*, and then in a more important step, these were crossed with Mexican and Central American species of sect. *Ellobium*. Some of the resulting strains were further crossed with species of other sections, such as *F. boliviana* (sect. *Fuchsia*) and *F. lycioides* (sect. *Kierschlegeria*). Although some other crosses were made that did not involve species of sect. *Quelusia*, these were far fewer and less popular than the quelusioid crosses. The final stage involved the exploitation and selection of mutations, which no longer depended upon the introduction of native material. In the remainder of this section, I will review the role of sect. *Quelusia* in the first two stages of fuchsia breeding, then summarize the present-day situation of sect. *Quelusia* species in cultivation.

Species introductions. With the possible exception of a short-lived introduction of *F. triphylla* in the early 18th century (Wright, 1975), *F. coccinea* was the first species of *Fuchsia* introduced into cultivation in Europe. Plants of this species were growing at Kew Gardens in London in 1788 (Aiton, 1789), and an illustration of it was published by Sims (1789). Hooker (1869) suggested that Sims's figure might have represented *F. magellanica* rather than *F. coccinea*, because of the prominent petioles on the lower leaves. This is clearly not the case, however, as the figure accurately represents the unique arching pedicels and ovate, subsessile upper leaves of *F. coccinea*, and Sims's own specimen deposited at Kew is *F. coccinea* (pers. obs.). Although Dryander stated that the plants he described were introduced from Chile (Aiton, 1789), the species is native to just a few mountains in Minas Gerais, Brazil.

The next introduction from sect. *Quelusia* was *F. magellanica*. An array of different variants of this species appeared in England in the 1820s

under several names, starting with *F. gracilis*, which was reported from the Edinburgh Botanic Garden in 1822 (Lindley, 1824). *Fuchsia conica* and *F. gracilis* var. *multiflora* were both introduced into England from Chile in 1824 (Lindley, 1827a, b). *Fuchsia discolor* was introduced from Port Famine in the Magellan Straits around 1830 (Lindley, 1835). I have seen no other evidence, such as old herbarium specimens from cultivated individuals, to indicate that *F. magellanica* was present in Europe prior to 1822. Soon after *F. magellanica* was introduced, however, it was confused with *F. coccinea* and was often cited as *F. coccinea* (see de Candolle, 1828, and Hooker, 1869).

Fuchsia regia was first grown in England between 1838 and 1840, under the name *F. radicans* (Lindley, 1841), and *Fuchsia alpestris* was cultivated in the Glasgow Botanic Garden as early as 1842 (Gardner, 1843).

Interspecific crosses. Interspecific hybridization among members of sect. *Quelusia* must have begun in the mid-1820s, but the first evidence for this was the appearance of *F. globosa* in a Horticultural Society exposition in London in 1832 (Lindley, 1833). Although the origin and parentage of this plant were not known to Lindley, the illustration and the description strongly suggest that it was a cross between *F. magellanica* and *F. coccinea*. A great proliferation of names of cultivars that were either variants of *F. magellanica* or crosses with *F. coccinea* followed in the next decades, including *F. riccartonii*, *F. tenella*, *F. recurvata*, and *F. corallina*. The history of these plants is unfortunately too poorly documented to determine their precise parentage, and names such as *riccartonii* have been applied to quite different cultivated strains (J. Wright, pers. comm.).

A major step in the search for novel, interesting traits in *Fuchsia* cultivars was the use of *F. fulgens*, a diploid species of the Central American section *Ellobium*, in crosses with selections from sect. *Quelusia*. One of the first such hybrids produced was exhibited in London in 1839, a cross of *F. fulgens* with *F. globosa* called "Standish's Fuchsia" (Lindley, 1840), which must have been either triploid or a spontaneously doubled hexaploid. Harrison (1841) also made a large number of crosses of *F. fulgens* with sect. *Quelusia* hybrids, publishing figures of the flowers of several of the different hybrids he selected. A hybrid between *F. cordifolia* (= *F. splendens*, sect. *Ellobium*) and *F. globosa* was grown in 1842, under the name *F. exoniensis* (Paxton, 1843). *Fuchsia regia* was also used in a series of crosses starting in 1840, leading to the development of darker petal color and improvement of flower shape (Wright, 1979). *Fuchsia boliviana*, a member of sect. *Fuchsia* from South America, may also have been used in the early crosses with selections of sect. *Quelusia* (J. Wright, pers. comm.).

The 19th-century crosses between members of sect. *Quelusia* and sect. *Ellobium* can be considered the "mainstream" fuchsias later treated collectively under the names *F. hybrida* Hort. (Siebert & Voss, 1896; Munz, 1943) and *F. speciosa* Hort. (Bailey, 1900). In the strictest sense, these names have been attributed to crosses between *F. magellanica* and *F. fulgens*. At the other extreme, they have been used to include almost all garden fuchsias. Reiter (1944) suggested that *F. hybrida* might best be treated as a horticultural complex including all cultivars of sects. *Quelusia* × *Ellobium* ancestry, including many of complicated origin.

Chaudhuri (1956) made cytological observations that suggest how crosses between *F. magellanica* and *F. fulgens* might have facilitated the rapid advances in fuchsia breeding during the mid-1800s. In his crossing experiments, the tetraploid ($n = 2x = 22$) *F. magellanica* and the diploid ($n = x = 11$) *F. fulgens* yielded triploid progeny in which a high percentage of unreduced gametes were produced. As a result, the F_1 crosses were partially fertile, and hexaploids ($6x$) were produced in the F_2 generation, as well as tetraploid ($4x$) and pentaploid ($5x$) individuals in the respective backcrosses. All of these crosses retained some degree of fertility. Crosses between *F. magellanica* and other diploids, such as *F. splendens* and *F. denticulata*, did not have the same propensity for unreduced gametes as *F. fulgens*, and their hybrids were largely sterile. Thus, *F. fulgens* may have been a critical species that helped prevent total sterility in crosses with the polyploid members of sect. *Quelusia* and with later cultivars of even higher ploidy levels.

More recently, J. O. Wright in England has confirmed Chaudhuri's findings, producing a complete set of $3x$ to $9x$ progeny, entirely by selfing and backcrossing the original *F. magellanica* × *F. fulgens* hybrids (J. Wright, pers. comm.). Wright further reports that none of these hybrids showed any obvious similarity to *F. fulgens*.

Fuchsia magellanica is the only species in sect. *Quelusia* able to withstand winter conditions with long periods of freezing temperatures, so that all of the hedge plants of fuchsia grown outdoors in England and Ireland are variants of this species or crosses with a strong *F. magellanica* parentage.

Many of the recent introductions from Brazil, however, such as *F. campos-portoi* and *F. coccinea*, are proving to be frost-resistant as well (J. Wright, pers. comm.).

Native species in cultivation today. Many of the early species introductions have been maintained for long periods of time in cultivation without crossing. Thus, Hooker (1869) was able to trace plants of *F. coccinea* found in the Oxford Botanic Garden in 1867 back to the original introduction of that species at Kew in 1788. Although this species may have been later lost from cultivation in England and Europe, it was successfully established on several of the Atlantic islands off the north African coast, such as Madeira, St. Helena, and the Canary Islands, in the early 1800s, persisting to present day (Hansen, 1969; A. Calero, pers. comm.). Plants of *F. alpestris* grown today in England and continental Europe have particularly small leaves similar to Gardner's type specimen and may well date back to his original introduction in 1842. Wild strains of *F. magellanica* are apparently still present in England, and the species has become widely naturalized in parts of Ireland, New Zealand, Hawaii, South America, and eastern and southern Africa.

As a result of the author's collections of native fuchsias in Brazil between 1985 and 1987, and seeds of different strains of *F. magellanica* obtained from Chile and Argentina, many new species and strains from sect. *Quelusia* have been recently introduced into cultivation. All the taxa recognized in this treatment, except *F. bracelinae* and *F. glazioviana*, are now in cultivation, with the most complete collections grown at the University of California Botanical Gardens at Berkeley and in the private garden of Mrs. Drude Reiman-Dietiker in the Netherlands. Other important collections include those of Mr. J. O. Wright in England, members of the different amateur fuchsia societies on the west coast of the U.S., and the Nederlandse Kring van Fuchsia-Vrienden in the Netherlands.

Systematic Treatment

Taxonomic history. The earliest known specimens of *Fuchsia* from South America were collected in the Magellan Straits around 1690 by George Handisyd, who was surgeon aboard the British ship *Modena* (Middleton, 1909). These collections correspond to *F. magellanica* and are deposited in the eighth volume of Hans Sloane's herbarium at BM. Louis Feuillée published the first description and illustration of this species under the name *Thilco* (Feuillée, 1725), but it was not taken up by Linnaeus, who described *Fuchsia* in 1753 in *Species Plantarum*. More specimens of *Fuchsia* were collected in the Magellan Straits in January of 1768 by Philibert Commerson, naturalist on the French survey expedition led by Louis de Bougainville. Commerson's specimens were examined by Lamarck, who designated them the type collection for *F. magellanica*, which he described in 1788. Another early collection of this species was made by Ruiz and Pavón between 1778 and 1788, near Concepción, Chile; they later described it as *F. macrostema* (Ruiz & Pavón, 1802).

Domingo Vandelli published the genus *Quelusia* in 1788, based on Brazilian plants. He did not name a species, and his description and illustration dealt mostly with the flower, making it difficult to distinguish which of the Brazilian species he was treating. José M. da C. Vellozo, a contemporary of Vandelli, described *Quelusia regia* from Brazil, providing locality information and an illustration that included leaves and flowers. Due to political problems, however, Vellozo's name for the species was not published until 1829 (Borgmeier, 1937; Carauta, 1973).

Jonas Dryander described *Fuchsia coccinea* in 1789 based on cultivated plants that had been introduced in England the previous year. The source of his plants remains unclear, however, since Aiton (1789) attributed their introduction from Chile by a Captain Firth, while Salisbury (1791) stated that they were brought from Brazil by Vandelli around 1787. In reprinting Vandelli's publication of *Quelusia*, Roemer (1796) added a footnote wherein he stated that Vandelli's genus was the same as Dryander's *F. coccinea*. Meanwhile, Salisbury (1791) had already synonymized *Quelusia* under *F. coccinea*.

In the first conspectus of the genus, de Candolle (1828) designated *Quelusia* as a section of *Fuchsia*; by that time, the identity of *F. magellanica* and *F. coccinea* were already badly confused, and de Candolle considered them to be synonymous.

Collections made in Brazil by Auguste de Saint-Hilaire between 1816 and 1822 resulted in the description of four new species by Jacques Cambessèdes in 1830. None of these species have been maintained in the present treatment, but the name *F. integrifolia* Camb. was long used for *F. regia*.

During the 1820s and 1830s, there was a sudden surge of collections of *Fuchsia* from Brazil and Chile, and many plants were shipped for cultivation in Europe. Several new taxa, most of them now included under *F. regia* and *F. magellanica*, were described by John Lindley, George Gardner, and Karel Presl. During the second half of the 19th

century, Auguste Glaziou made extensive collections in eastern Brazil, when this area was off limits to most foreign botanists. The rare *F. glazioviana* was described from one of his finds.

During the first half of this century, Curt Brade and Ynes Mexia collected fuchsias from the two highest peaks of southern Brazil, Pico da Bandeira and Itatiaia. Their collections led to the description of two local endemics, *F. bracelinae* and *F. campos-portoi*.

The leading figure in *Fuchsia* taxonomy was Philip Munz, who published a comprehensive revision of the genus in 1943. He refined the sectional concepts and limited sect. *Quelusia* to a closely knit group of species from Brazil and one from the southern, temperate Andes. He recognized five species in the section, as well as *F. hybrida*, which covered most of the cultivated hybrids. Two of his species were polytypic: *F. magellanica* had three varieties, and *F. regia* four.

Since Munz, many new collections have accumulated, especially from the southern states of Brazil, where Balduíno Rambo, Raulino Reitz, Roberto Klein, and Gert Hatschbach have made significant contributions. Their collections have led me to recognize four new taxa of *Fuchsia* from the south of Brazil in this treatment. During two field trips in 1985 and 1987, I was able to collect and study field populations of all the Brazilian taxa.

Criteria for taxonomic rank. In distinguishing species within the section, I attempted to recognize basic, morphologically definable units that are also correlated with geographical, ecological, or cytological discontinuities between populations. It is assumed that these units also reflect the evolutionary divergences that have taken place in the group, but such hypotheses must be subjected to much more rigorous testing methods before they can be substantiated.

Subspecific rank was used when a wide-ranging species exhibited geographically or ecologically distinct morphological variants, but these were linked by intermediate populations along localized areas of sympatry.

Although different varieties have been recognized in the past for some species of *Fuchsia*, there is little biological basis for recognizing varieties. Similar pale color variants, for example, have appeared independently in a series of geographically distinct populations of *F. magellanica*, and they are probably the result of a single, recessive gene mutation (Chaudhuri, 1956). I do not consider this kind of variation worthy of formal taxonomic recognition in a biosystematic revision such as this, although I do recognize the utility of assigning names to such plants for horticultural purposes.

In widespread species, such as *F. regia* and *F. magellanica*, it has not been feasible to distinguish the genetic basis for the many minor variants that exist from environmentally induced variations or inherent plasticity in the plants. Most likely, genetically determined variations will best be recognized through careful observation of plants cultivated under uniform growing conditions. In this way, amateur and professional nurserymen can make valuable contributions to our taxonomic understanding of sect. *Quelusia* in the future, especially if they maintain well-documented records of the provenance of their stock and the constancy and inheritance patterns of the different characters.

In view of the uncertain phylogeny of the species of sect. *Quelusia*, they are listed as follows in alphabetical order.

Fuchsia section **Quelusia** (Vandelli) de Candolle, Prodr. 3: 36. 1828. *Quelusia* Vandelli, Fl. Lusit. Brasil., 23, fig. 10, 1788; Roemer, Script. Pl. Hisp. Lusit. Brasil., 101, tab. 7, fig. 10. 1796. LECTOTYPE: *Fuchsia coccinea* Dryander. *Quelusia* was published without the protologue naming a species, but Vandelli's original text and engraving were reproduced by Roemer, who stated in a footnote that the description corresponded to *F. coccinea*. Salisbury (1791) and de Candolle (1828) treated *F. coccinea* as the type of *Quelusia*. Therefore, Munz's (1943) choice of *F. magellanica* as the lectotype of *Quelusia* and Berry's (1982) designation of *F. regia* as the lectotype cannot be upheld.

Erect, scandent or climbing shrubs, subshrubs, or lianas. Leaves opposite or whorled. Flowers hermaphroditic, pendulous and axillary near the branch tips. Sepals normally reddish, longer than the floral tube and connate at the base. Petals purple, strongly convolute, erect, shorter than the sepals. Stamens erect, exserted beyond the sepals, the antisepalous filaments longer than the antipetalous ones. Pollen grains triporate or occasionally 4-porate, with segmented-beaded viscin threads. Nectary adnate to the base of the floral tube, smooth or ridged. Stigma clavate to subglobose, obscurely 4-cleft at the apex. Berries with ca. 60–120 seeds. Gametic chromosome number $n = 22, 44$.

Distribution (Fig. 1). Southeastern Brazil, from Minas Gerais to Rio Grande do Sul, and the Andes

of southern Chile and Argentina from 33°S to 55°S latitude.

Etymology. The name *Quelusia* was given by Vandelli after Queluz, the summer palace of Portuguese royalty located outside of Lisbon (Don, 1832).

Common names. Chile: chilco, chilca, palo blanco, fucsia, tilco. Brazil: brinco de princesa.

KEY TO THE SPECIES OF *FUCHSIA* SECTION *QUELUSIA*

Note: Leaf measurements are based on mature, fully expanded leaves. Dimensions are intended to cover the full range of dry and fresh specimens.

1a. Petioles mostly 1–3 mm long, pilose.
  2a. Leaves elliptic, with acute to rounded base, pilose on all veins below; pedicels hanging, 12–20 mm long ..... 2. *F. bracelinae*
  2b. Leaves ovate, with subcordate base, pilose mostly on lower ⅓ of midvein below; pedicels divergent from stems and pendent only in distal ⅓, 18–50 mm long ..... 5. *F. coccinea*
1b. Petioles mostly more than 3 mm long, glabrous to pilose.
  3a. Sepals connate at the base (from the point of petal insertion) for ≥ 8 mm and ≥ ⅓ of their total length.
    4a. Petioles mostly 4–8 mm long, leaves 10–25 mm wide, upper surface lightly sulcate-nerved; stipules inconspicuous ..... 3. *F. brevilobis*
    4b. Petioles mostly 10–25 mm long, leaves 25–45 mm wide, upper surface smooth; stipules crassate and persistent ..... 9. *F. regia* subsp. *serrae*
  3b. Sepals connate at the base for 2–7 mm and ≤ ¼ of their total length.
    5a. Leaves 2–6 mm wide, narrowly lanceolate; floral tube subrhombic, 4–6 mm long ..... 4. *F. campos-portoi*
    5b. Leaves ≥ 8 mm wide, less than 5 times as long as wide; floral tube cylindrical-fusiform, 5–35 mm long.
      6a. Leaves 15–30 mm long, 8–15 mm wide, densely grouped on branches with internodes 3–12 mm long; floral tube 5–7 mm long and glabrous ..... 6. *F. glazioviana*
      6b. Leaves longer or wider than above, internodes > 12 mm long; *or* floral tubes pubescent or > 7 mm long.
        7a. Petioles ≤ 6 mm long, leaf blade > 8 times as long as the petiole, leaves mostly opposite.
          8a. Plants glabrous, leaves 8–15(–30) mm wide; floral tube 10–15 mm long ..... 7. *F. hatschbachii*
          8b. Plants densely pilose, leaves 20–70 mm wide; floral tube 5–9 mm long ..... 1. *F. alpestris*
        7b. Petioles (3–)5–35 mm long, leaf blade < 6 times as long as the petioles, some or all leaves ternate or whorled.
          9a. Mostly erect shrubs; leaves membranous, usually glabrous, 15–60 mm long; margin serrulate and often shallowly lobed between teeth; petioles 0.3–1 mm thick; floral tube mostly 2–3.5 mm wide; berry narrowly oblong, 4–7 mm thick when ripe; southern Chile and Argentina ..... 8. *F. magellanica*
          9b. Mostly scandent shrubs or lianas; leaves membranous to coriaceous, glabrous to pilose, 20–140 mm long; margin entire to gland-serrate; petioles 1–3 mm thick; floral tube 3–7 mm wide; berry oblong, ellipsoid, or globose, 9–13 mm thick when ripe; Brazil ..... 9. *F. regia*

1. Fuchsia alpestris Gardner, Bot. Mag. 69: tab. 3999. 1843. TYPE: Brazil. Rio de Janeiro: Organ Mountains, "in moist, bushy, rocky places," 1,570 m, Mar. 1841, *George Gardner 5706* (holotype, OXF; isotypes, BM, CGE—2 sheets, G, GH, K—2 sheets, NY, P, UC, W). Figure 4.

Fuchsia mollis Krause, Engl. Jahrb. 37: 600. 1906. TYPE: Brazil. Rio de Janeiro: in forest near Nova Friburgo, 900 m, Oct. 1896, *E. Ule 4418* (holotype, B, destroyed in World War II, photograph at F; isotypes, CORD, R—#41706, RB).

Scandent shrubs 1–5 m tall, branches generally long and hanging, up to 5 m long. Branchlets reddish tan, densely pilose with erect, whitish hairs ca. 1 mm long. Leaves opposite, occasionally ternate, membranous, oblong, broadly ovate or narrowly elliptic-ovate, (55–)60–140 mm long, 20–70 mm wide, apex acute to acuminate, base rounded to subcordate or subauriculate, moderately pilose above, densely pilose below, sometimes purple-flushed when young, often yellowing before dehiscing; margin entire to subdenticulate, secondary veins 5–9(–10) per side. Petioles densely pubescent, 3–6 mm long, stout and 2–4 mm thick on older leaves, canaliculate above. Stipules narrowly triangular, 1–2 mm long, 0.8–1.5 mm wide, adjacent ones sometimes fused, generally covered by hairs. Flowers few and solitary in upper leaf axils; pedicels pendulous, 25–40 mm long. Ovary

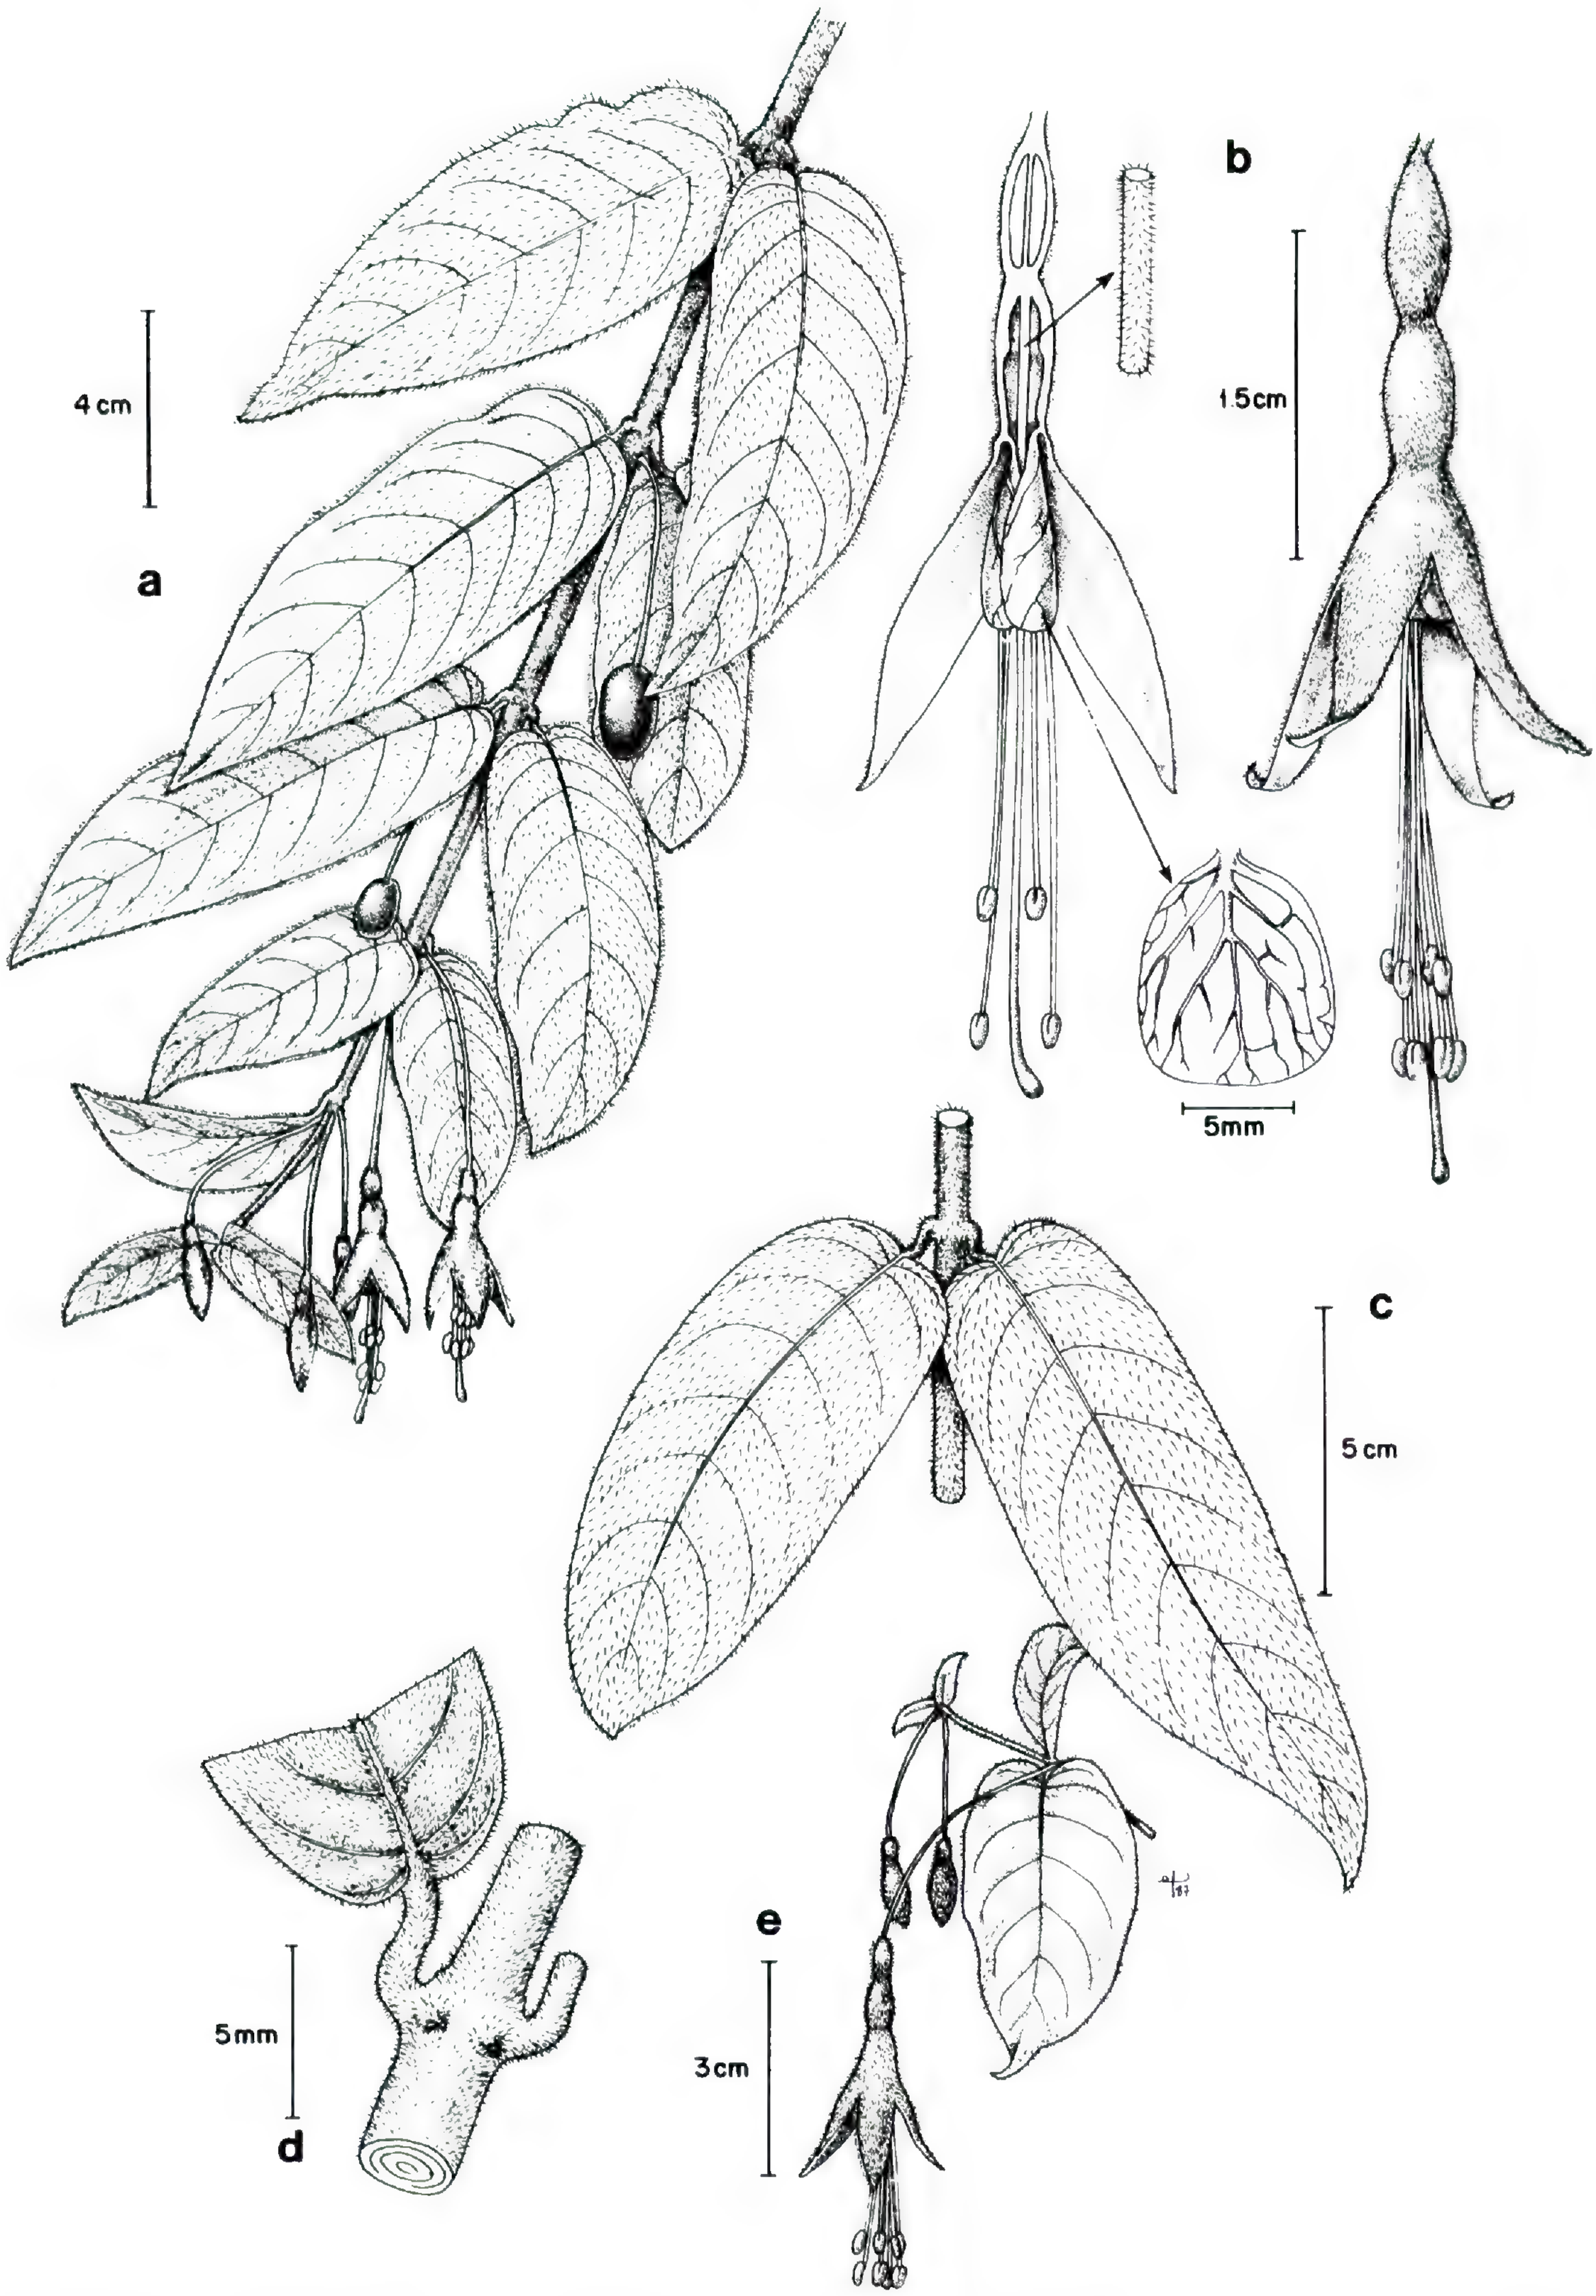

FIGURE 4. *Fuchsia alpestris.*—a. Flowering branch.—b. Details of entire and longitudinally split flower.—c. Pair of large leaves from basal portion of stem.—d. Detail of young stem with stipules and petioles.—e. Tip of flowering shoot with nearly sessile leaves. From *Berry et al. 4418.*

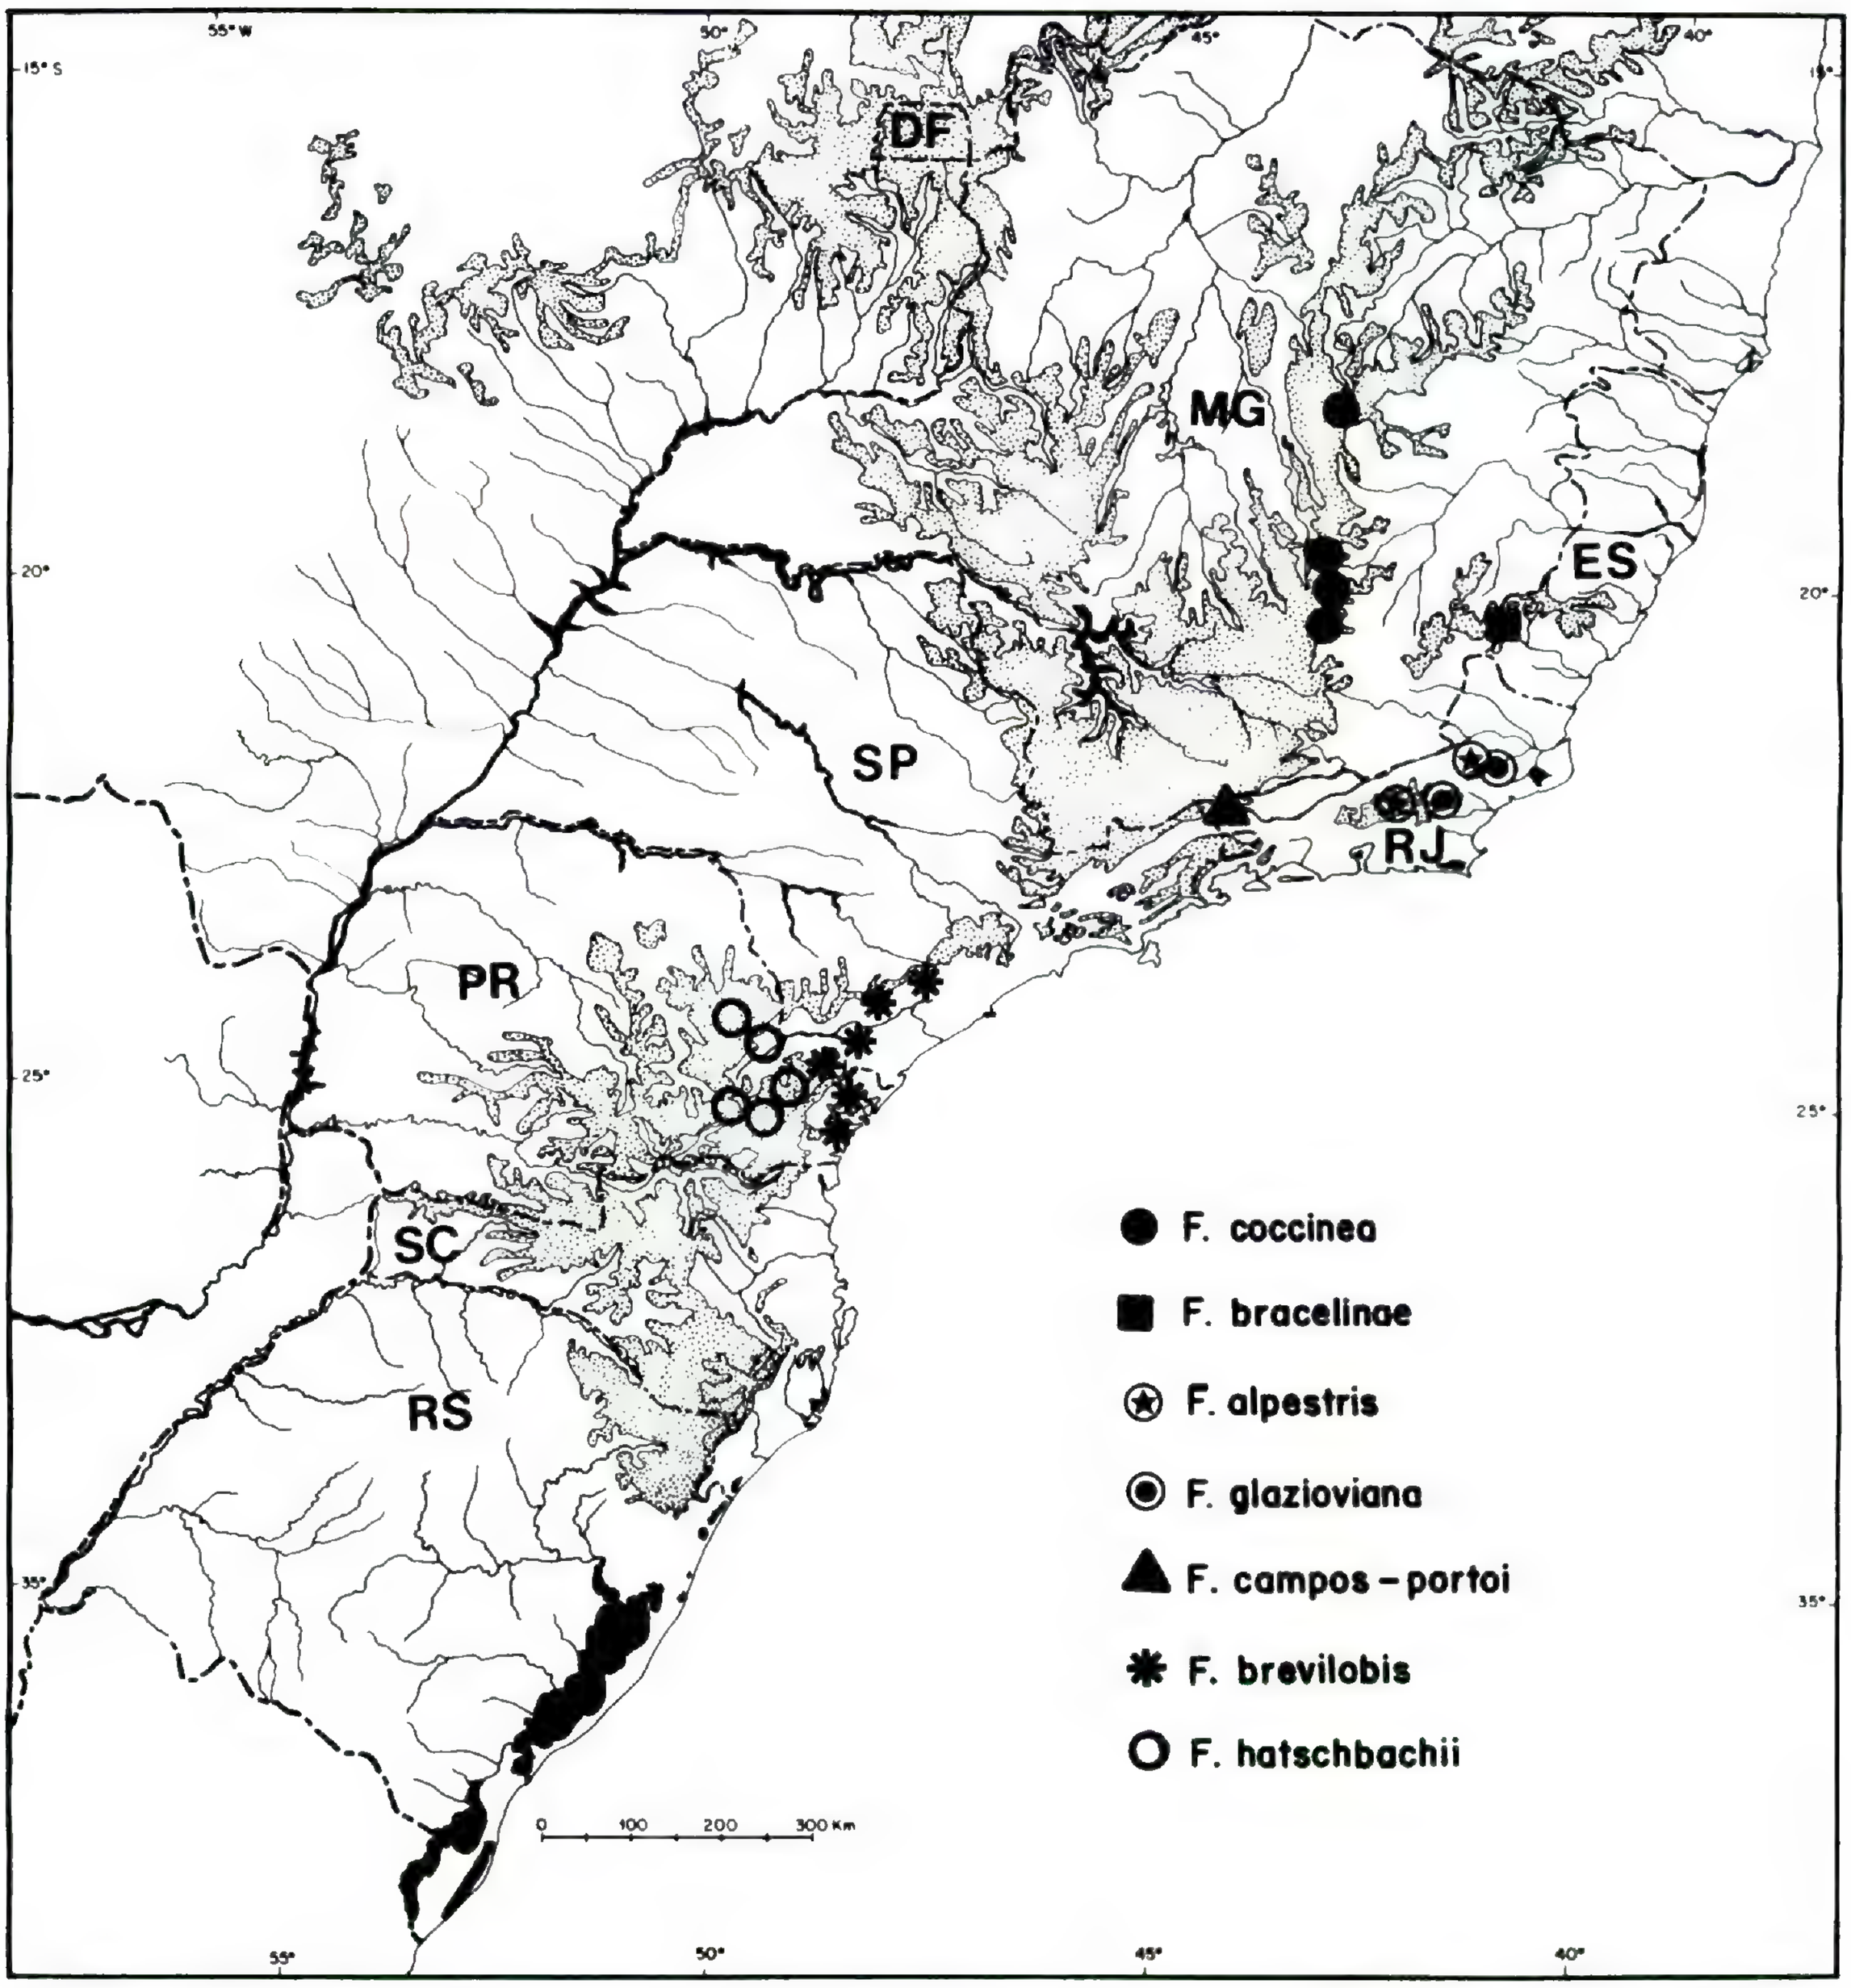

FIGURE 5. Geographical distributions of the Brazilian species of *Fuchsia* sect. *Quelusia*, except for *F. regia*. Contours higher than 800 m are indicated by the stippled areas. Capital letters are state abbreviations. MG = Minas Gerais, ES = Espirito Santo, RJ = Rio de Janeiro, SP = São Paulo, PR = Paraná, SC = Santa Catarina, RS = Rio Grande do Sol.

subquadrangular, pilose, 6–8 mm long, 2–3.5 mm wide. Floral tube cylindrical-fusiform, (5–)6–8(–10) mm long, 3–4 mm wide, pubescent outside, pilose inside; nectary 4–6 mm high, 1 mm thick, irregularly ridged. Sepals 18–26(–28) mm long, connate for 4–6 mm at the base, pilose outside; free lobes 3.5–4.5 mm wide at base, spreading at anthesis. Tube and sepals red to dull pink. Petals violet, broadly obovate, 10–14 mm long, 8–9 mm wide. Filaments red, 26–35 mm and 24–32 mm long; anthers red, oblong, 2.5–3.5 mm long, 1.2–1.6 mm wide. Style red, pilose in basal ⅓; stigma red, clavate, 2.5–3.5 mm long, 1.1–1.6 mm wide. Berry oblong-ellipsoid, 14–16 mm long, 8–10 mm wide, purple when ripe; seeds oblong, 1.8–2.2 mm long, 1–1.5 mm wide. Gametic chromosome number $n = 22, 44$.

Distribution (Fig. 5). In thickets and low forest near granitic outcrops of several morros in north-central Rio de Janeiro state, Brazil: near Nova Friburgo, Santa Maria Madalena, and in the

Serra dos Órgãos between Teresópolis and Petrópolis, (1,100–)1,400–1,600 m. Flowers mainly from November to March.

Additional specimens examined. BRAZIL. RIO DE JANEIRO: Teresópolis, *Bailey & Bailey 1296* (BH), *von Bayern 19539* (F, NY), *von Bayern in Sep. 1888* (M); 26 km SE of Itaipava, road from Teresópolis to Petrópolis, *Berry et al. 4418* (MO, RB; $n = 22$); Fazenda Portugal, Serra dos Órgãos, *Brade 19467* (RB); Canoas, Sítio Sumare II, Teresópolis to Nova Friburgo, *Braga 1535* (RB); Petrópolis, *Rgl. 55-11, 56.9* (LE); Morro do Sertão, Petrópolis, *Goés & Dionisio 427* (RB); Araras, Mun. Petrópolis, *Martinelli & Sucre 216* (RB); Araras, Morro Bolo de Milho, *Sucre & Braga 2808* (RB); Nova Friburgo, *Riedel 534* (LE), *Fomnov 4418* (CORD); Pedra Dubois, Santa Maria Madalena, *Anderson 11724* (MO).

Cultivated specimens. U.S.A. CALIFORNIA: Berkeley, from Brazilian plant, *Bracelin 2575* (RSA). THE NETHERLANDS: Hollandsche Rading, *Berry & Brako 001-86* (MO; $n = 44$). Also seen cultivated in England and France.

Munz (1943) treated *Fuchsia alpestris* as a variety of *F. regia*, but the former can be readily distinguished from *F. regia* by having large, mostly opposite, short-petioled leaves. The older leaves have a characteristic subcordate base, and the entire plant has characteristic dense, pale pubescence. The flowers are considerably smaller and often much paler than those of the subspecies of *F. regia* that occurs in the same area.

This species is rare in nature and is apparently confined to shrubby patches bordering exposed rock on the flanks of large, granitic domes. *Fuchsia regia* subsp. *regia* always occurs nearby, and some intergradation between the two species has been found at Pedra Dubois, near Santa Maria Madalena (see Appendix).

2. Fuchsia bracelinae Munz, Proc. Calif. Acad. Sci., Ser. 4, 25: 7, pl. 1, fig. 2. 1943. TYPE: Brazil. Espírito Santo: Serra do Caparaó, rocky open campo, 2,650 m, 25 Nov. 1929, *Ynes Mexia 4013* (holotype, GH, photograph at BH; isotypes, A, BM, CAS, G—DEL, GH, MO, NY, P, S, UC, US, Z). Figure 6.

Few- to many-branched subshrubs 10–60 cm tall, or occasionally scandent shrubs to 2 m high in dense shrubbery. Branchlets terete, generally reddish purple, densely pilose with erect, whitish hairs ca. 1 mm long; older branches with freely exfoliating bark. Leaves 3–5-verticillate, membranous, narrowly elliptic-lanceolate, 20–50 mm long, 7–17 mm wide, apex narrowly acute, base rounded, green and slightly strigose above with conspicuously impressed veins, paler and usually purple-flushed below and densely pilose on the sulcate veins and margins; margin subentire to gland-denticulate, secondary veins 4–7 per side. Petioles green to reddish, pilose, 1–3 mm long. Stipules lanceolate, with a thick base, 1.5–2 mm long, adjacent ones often fused basally, subpersistent. Flowers solitary in upper leaf axils; pedicels slender, pilose, pendulous, 12–20 mm long. Ovary oblong, strigillose to pilose, 4.5–8 mm long, 2–3 mm wide. Floral tube cylindrical-fusiform, 3.5–7 mm long, 2–4 mm wide, lightly strigillose to pilose outside, glabrous inside; nectary 2.5–3.5 mm high, ca. 1 mm thick and slightly ridged. Sepals 19–26 mm long, narrowly lanceolate to elliptic-ovate, connate at the base for 3–5(–6) mm; free lobes 5–8 mm wide at the base, apex acuminate, spreading at anthesis. Tube and sepals light red to pink. Petals deep violet, broadly obovate, 10–15 mm long, 6.5–9 mm wide, apex rounded. Filaments reddish purple, 24–30 mm and 17–21 mm long; anthers elliptic, 2.5–3 mm long, 1.2–1.6 mm wide. Style light red, glabrous; stigma reddish, clavate to subglobose, 1.5–3 mm long, 1–1.5 mm wide, exserted 5–14 mm beyond the anthers. Young fruits oblong, mature ones not seen. Gametic chromosome number $n = 22$.

Distribution (Fig. 5). Endemic to the highest peaks of the Serra do Caparaó (Pico da Bandeira, Pico do Cristal, Pico do Cruzeiro, and Pico do Calçado) along the border of the states of Minas Gerais and Espírito Santo. Grows in open campo above treeline, between 2,280 and 2,850 m, most common at 2,700–2,800 m. Flowers in the summer, principally from November until March.

Additional specimens examined. BRAZIL. ESPÍRITO SANTO: Pico da Bandeira, *Berry 4524* (MO, RJ; $n = 22$), *4530, 4532, 4533, 4534, 4535* (MO, RJ; $n = 22$); *Irwin 2745* (F, MICH, NY, R, TEX, UC). MINAS GERAIS: Pico da Bandeira, *Berry 4525* (MO, RJ), *4531* (MO, RJ; $n = 22$); Campos de Caparaó, *Ule in 8 Feb. 1890* (R #41703); *Schwacke in 8 Feb. 1890* (R #41702); Serra do Caparaó, *Torgo 6* (HB, MBM).

Fuchsia bracelinae is distinguished from other members of the section by having dense, stiff pubescence and small, narrow, verticillate leaves. It inhabits only the rocky, open campos of the highest peaks of southern Brazil, in the Serra do Caparaó. Individuals are found along rocks, in meadows, or in protected shrub and bamboo patches. This area is subject to frequent and severe winter frosts, and *F. bracelinae* is found to within 60 m of the 2,897-m-high summit of Pico da Bandeira. Extensive winter dieback of the above-ground stems probably accounts for the small stature of most plants, but underground stems lead to extensive vegetative reproduction in areas with good soil accumulation.

Fuchsia regia occurs lower down on the same mountain range, but there is no sympatry at pres-

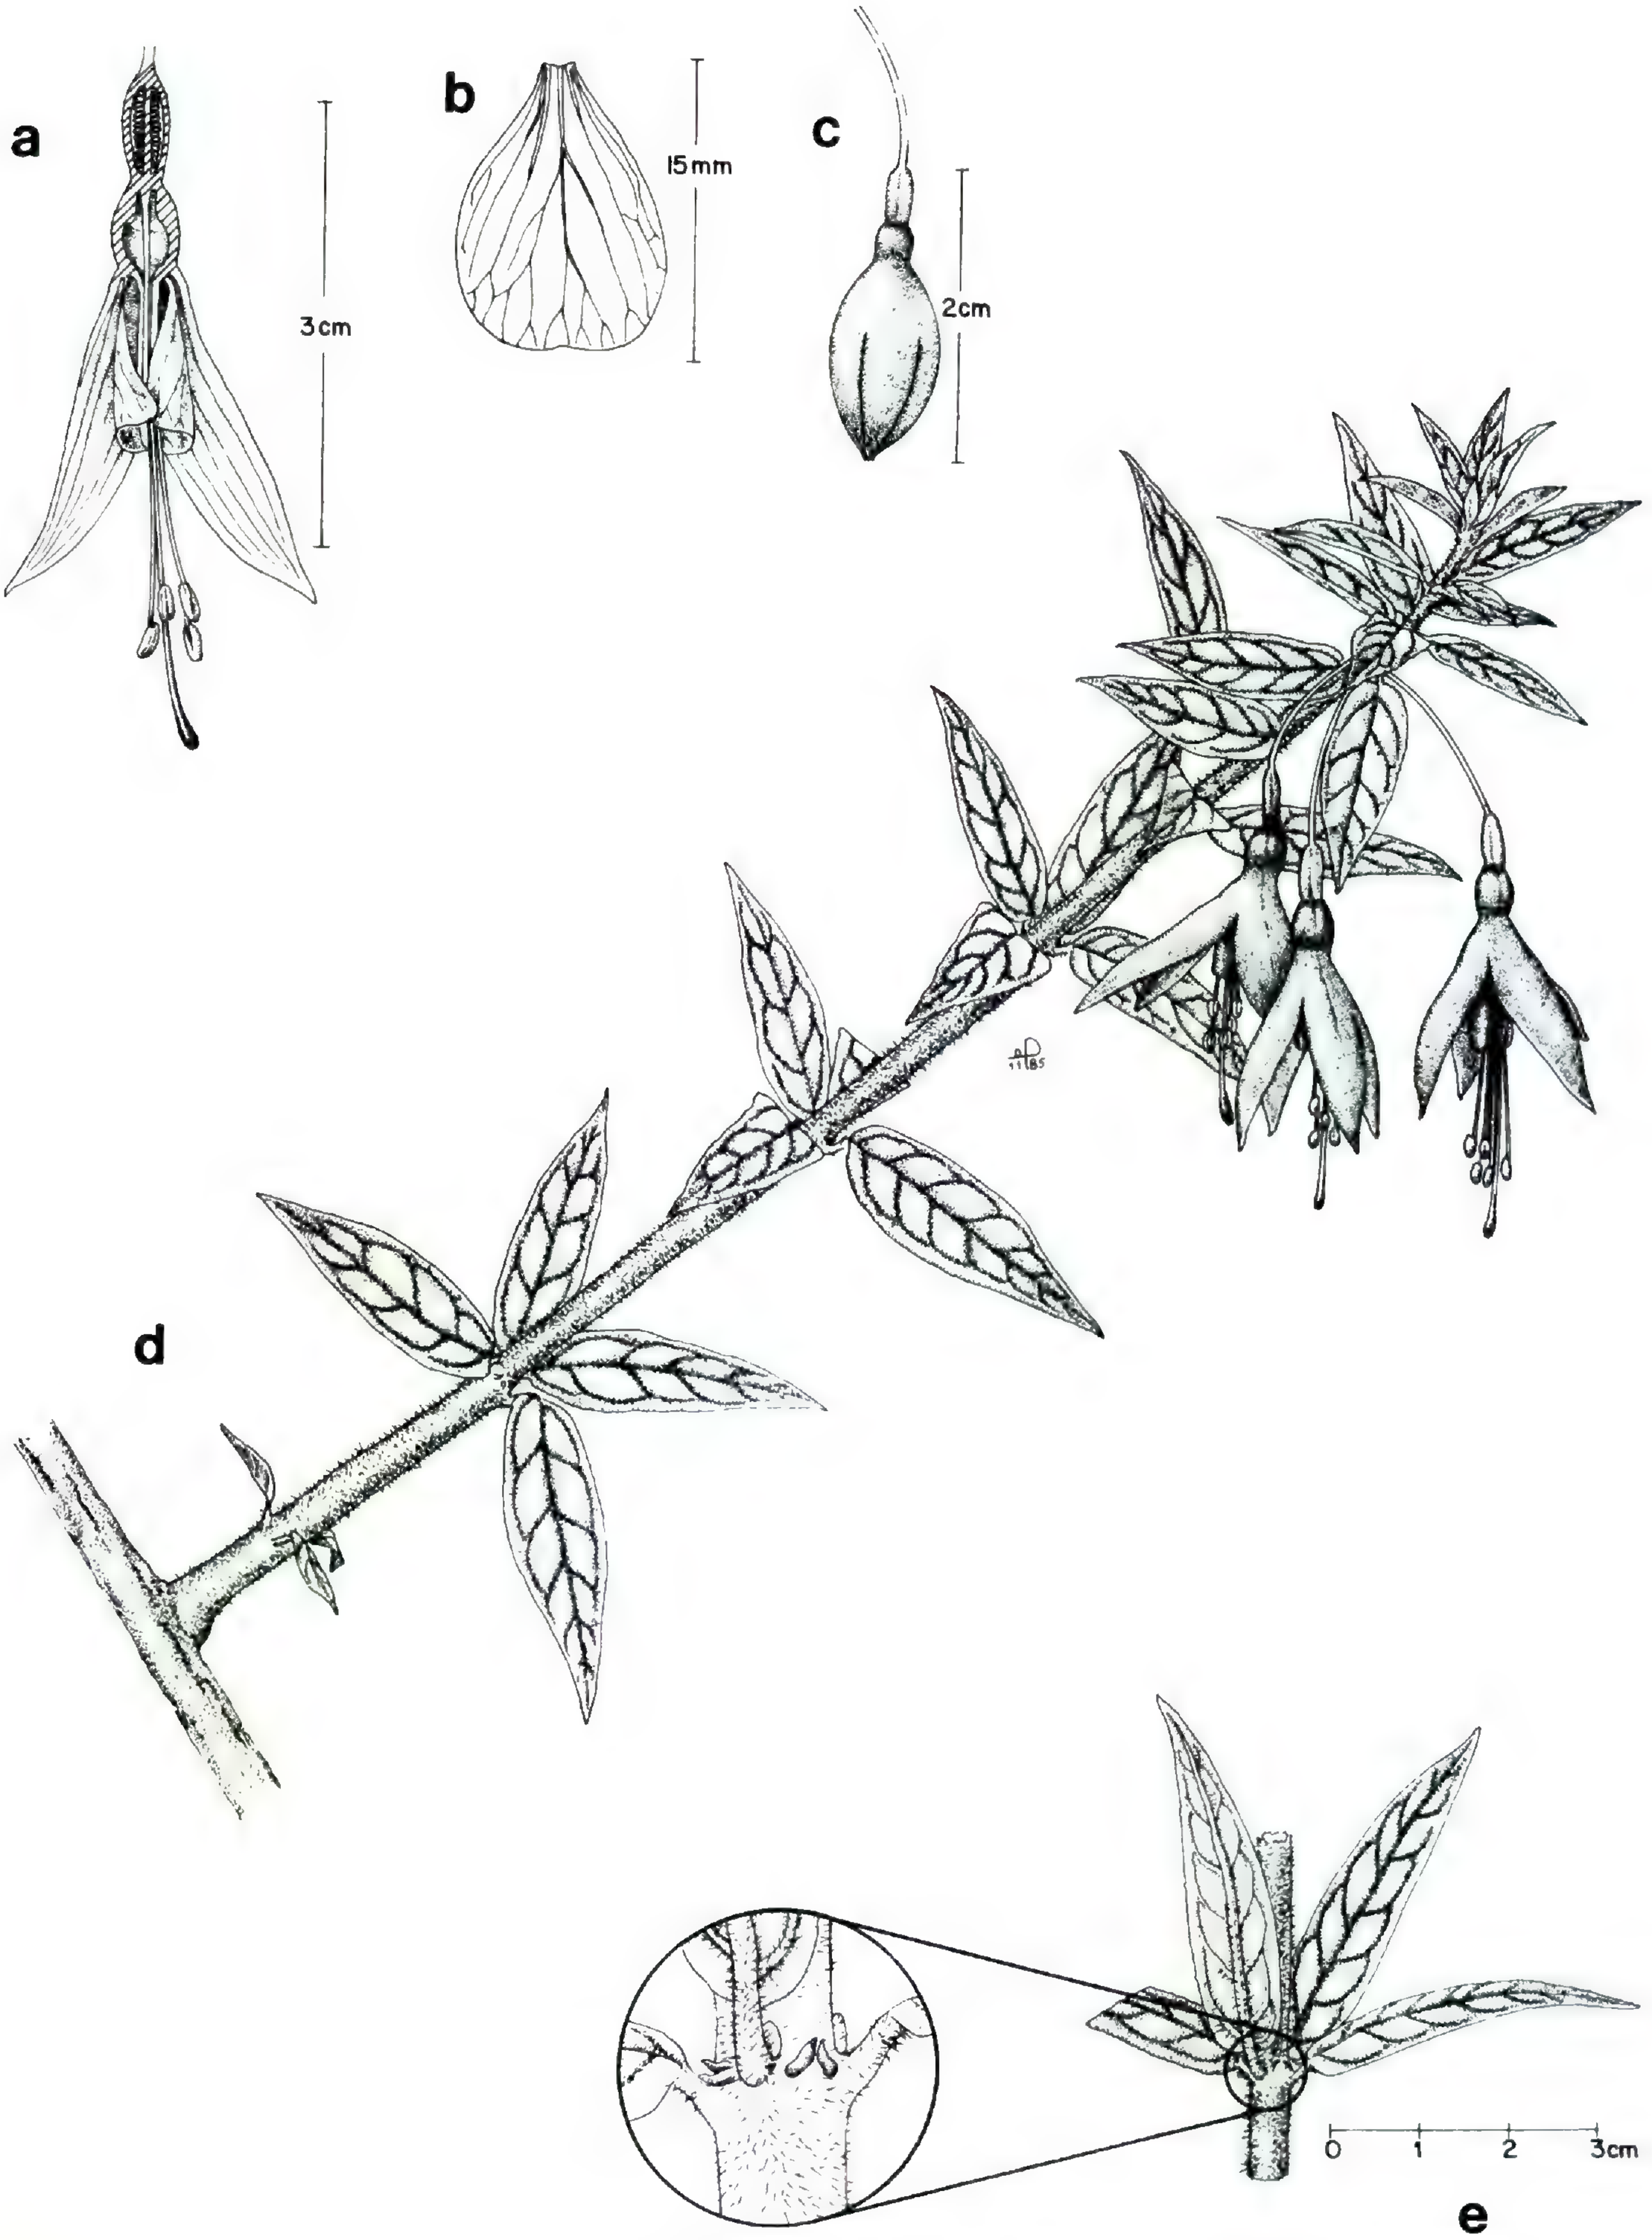

FIGURE 6. *Fuchsia bracelinae.*—a. Detail of flower in longitudinal section.—b. Petal, spread open.—c. Floral bud just prior to anthesis.—d. Flowering branch.—e. Leaf whorl and detail of stipules and petioles. From *Berry et al. 4524.*

ent; extensive forest areas at intermediate elevations existed until the past century but have been eliminated by cutting and fires. The collection *Irwin 2808* (US #2324661; Serra do Caparaó, 2,600 m) has narrow, moderately dentate leaves that resemble *F. campos-portoi*, but the Irwin collection is probably just a stunted individual of *F. bracelinae*.

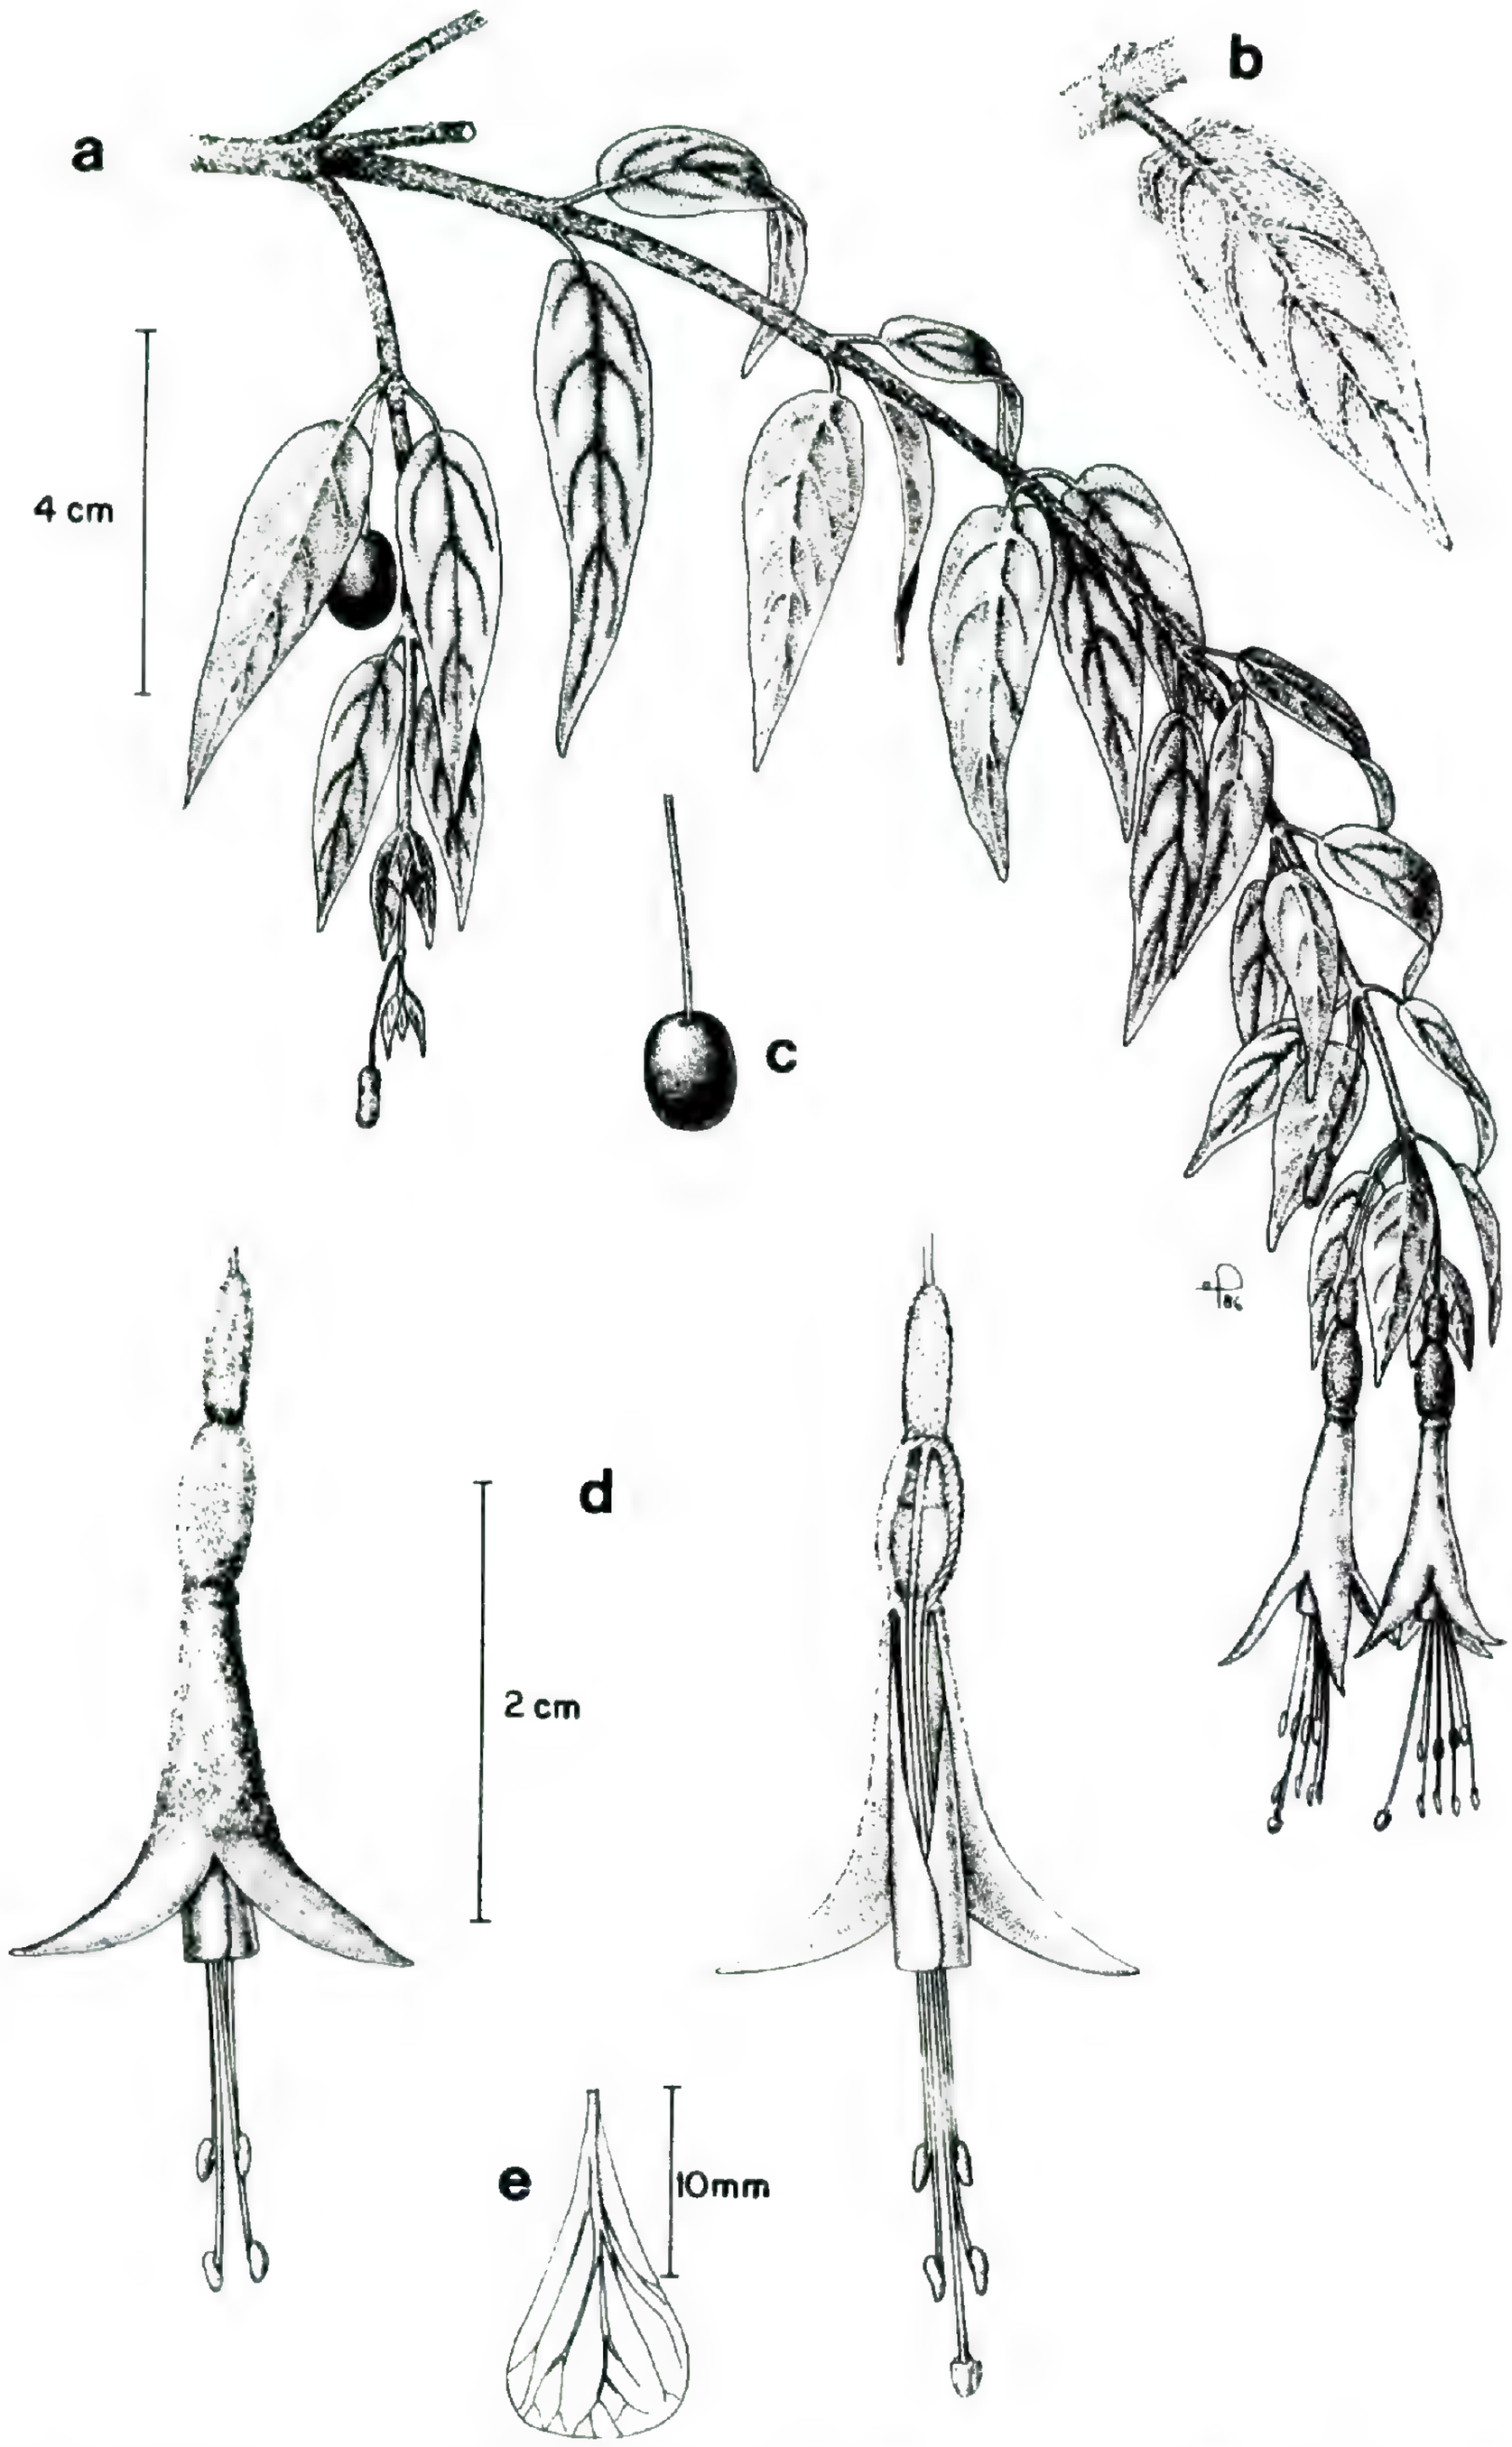

FIGURE 7. *Fuchsia brevilobis.*—a. Flowering branch.—b. Leaf detail.—c. Ripe fruit.—d. Detail of entire and longitudinally split flower.—e. Petal, spread open. From *Berry et al. 4441.*

3. Fuchsia brevilobis P. Berry, sp. nov. TYPE: Brazil. São Paulo: 38 km NE of the São Paulo–Paraná border near the 267 km post on Highway 116, bamboo forest on marshy ground, 680 m, 8 Mar. 1976, *Gerrit Davidse, T. P. Ramamoorthy & D. M. Vital 10902* (holotype, MO #2931564; isotype, SP (under *Davidse & D'Arcy 10902*); $n = 22$, $2n = 44$. Figure 7.

Frutex scandens, ramulis foliisque junioribus puberulentibus vel pilosis. Folia membranacea, lanceolata vel elliptico-ovata, basi rotundata, apice acuta, 2–7.5 cm longa, 1–3 cm lata, nervis secundariis 3–6; petiolis (2–)4–8(–14) mm longis. Tubi florales fusiformes 7–10

mm longi. Sepala 17–25 mm longa, basi (8–)11–16 mm connata, lobis liberis 5–11(–13) mm longis. Petala spathulata 12–18 mm longa, 5–7 mm lata, a tubo sepalorum fere occulta. Numerus gameticus chromosomatum $n = 22$.

Scandent shrubs 2–6 m tall, or occasionally lianas in trees to 8 m high, with basal stems 1–6 cm in diameter; branches scandent or drooping to 3 m long. Young growth densely pilose to puberulent, older stems exfoliating. Leaves opposite, ternate or occasionally in whorls of 4, firmly membranous, lanceolate to narrowly ovate, 20–75 mm long, 10–25(–30) mm wide, acute to occasionally acuminate at the apex, rounded at the base, subglabrous to sparsely pubescent above with impressed veins, sparsely puberulent to villous below, especially along nerves; margin entire to remotely denticulate, secondary veins 3–6 per side. Petioles usually dull purple, (2–)4–8(–14) mm long, subglabrous to densely pilose. Stipules 0.5–1.1 mm long, 0.7–1.2 mm wide, purplish, broadly triangular, thick-stubby and divergent, deciduous. Flowers solitary in upper leaf axils; pedicels pendulous, 17–28(–42) mm long. Ovary oblong, 5–10 mm long, 2–4 mm wide, loosely pilose, green. Floral tube subcylindric to fusiform, 7–10 mm long, 2–3 mm wide at the base, 3.5–4.5 mm wide in the middle, often constricted to ca. 3 mm wide at the point of insertion of the stamens beneath the widening of the sepal tube, glabrous to pilose outside, pilose inside; nectary green, slightly ridged, 1–1.2 mm thick and 2.5–3 mm high. Sepals 17–25 mm long, connate for (8–)11–16 mm at the base and forming a tube, this enlarging to 8–10 mm wide before the separation of the sepals; the free lobes narrowly triangular, 5–11(–13) mm long, 3–5 mm wide at the base, acute to acuminate at the apex, spreading to slightly recurved at anthesis. Tube and sepals red to red-pink. Petals almost entirely enclosed by the sepal tube, light to dark purple, spathulate, 12–18 mm long, (5–)6–7 mm wide, rounded at the apex, the base slender and adnate to the sepal tube in the basal 3–4 mm above the insertion of the filaments. Filaments reddish pink, 22–38 mm and 19–35 mm long; anthers red-purple, oblong, 2.5–3 mm long, 1–1.5 mm wide. Style reddish, pilose in lower half; stigma clavate, purple, 1.2–1.6 mm long, ca. 1 mm wide, exserted 5–10 mm beyond the anthers. Berry oblong-ellipsoid, 15–22(–26) mm long and 7–10(–16) mm wide at maturity, black when ripe; seeds oblong-triangular, 2–2.6 mm long, 1–1.6 mm broad, ca. 0.5 mm thick. Gametic chromosome number $n = 22$.

Distribution (Fig. 5). In montane forest of the Serra de Paranapiacaba in southern São Paulo state; in Paraná state in the Serra da Virgem Maria and Rio Capivari drainage, and then on the lowermost slopes of the Serra do Mar and in coastal restingas, from sea level to 900 m. Flowers throughout the year, principally from November to March.

Additional specimens examined. BRAZIL. SÃO PAULO: Reserva Carlos Botelho, between São Miguel Arcanjo & Sete Barras, *Prance et al. 6860* (MBM, SP, UEC); Reserva Capão Bonito, 70 km S of Itapetininga, *Sakane 543* (SP); 50 km S of Itapetininga, *Gibbs et al. 3279* (SP, UEC); Juquía to Tapiraí (on BR-478 S of Piedade), *Yamamoto 14653* (UEC); 38 km NE of SP-PR border, km 267 of BR-116, *Davidse & D'Arcy 10904* (MO); Apiaí-São Paulo, km 294, *Vianna in 5-5-64* (ICN #2820). Fuchsia brevilobis is distinguished by its remarkably long sepal tube, which almost entirely encloses the petals, and by the membranous, pubescent, narrowly ovate leaves. There are two distinct areas where this species occurs, with notable morphological differences in their populations. In the low ramifications of the Serra do Mar in northern Paraná and southern São Paulo states, plants grow between 700 and 900 m and are very pubescent, with especially long sepal tubes. Another group of populations is found on the lower, eastern flanks of the Serra do Mar in central Paraná, from 400 m to sea level. Most plants from these populations have longer petioles than those of higher altitude, and they vary considerably from population to population in color (dull pink to bright red), degree of sepal connation, and leaf shape and texture.

Several populations of *F. brevilobis* occur in the restinga or swamp forest close to sea level, a very

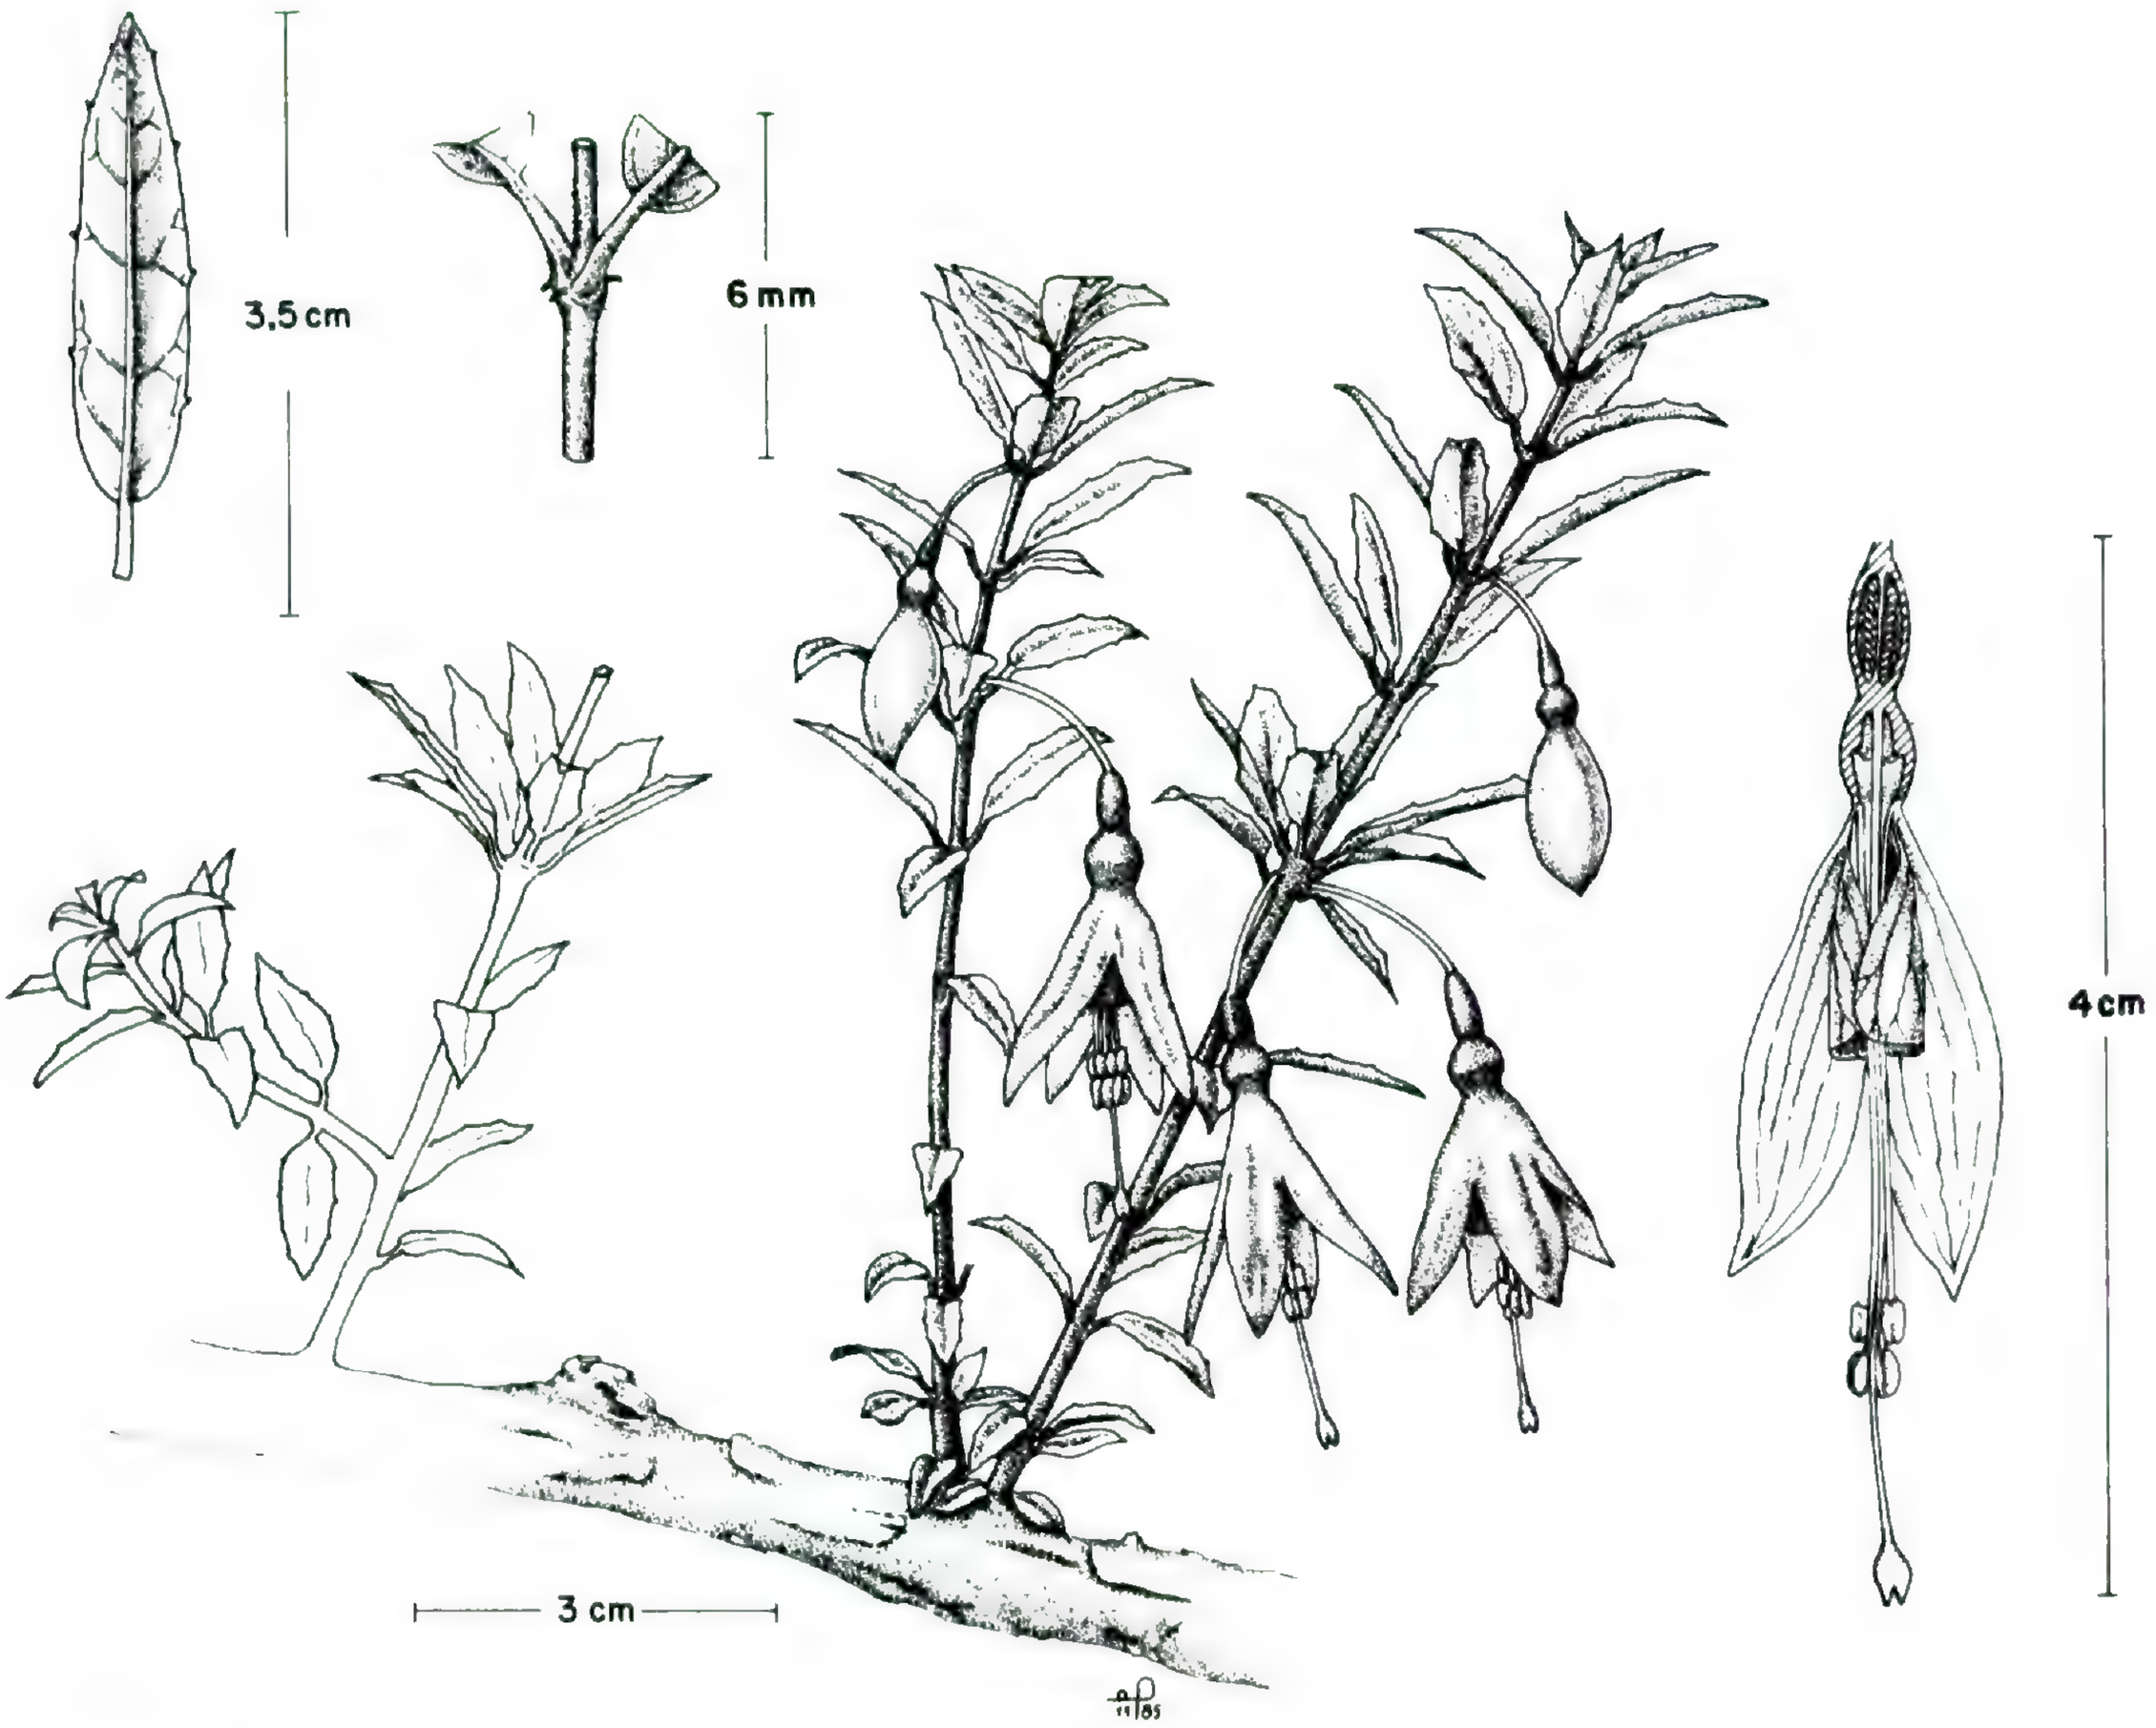

FIGURE 8. *Fuchsia campos-portoi*. Flowering shoots with details of an individual leaf underside, a leaf node with stipules, and a longitudinally divided flower. From *Berry et al. 4435*.

unusual habitat for Brazilian fuchsias. These plants grow as lianas and are found along rivers or streams, perhaps enabling them to withstand the heat and high evapotranspiration of the Atlantic lowlands. The population from Cacatu has unusually narrow, lanceolate leaves with acuminate tips.

Throughout most of its range, this species is sympatric with *F. regia* subsp. *serrae*. The presence of plants morphologically intermediate between the two taxa indicates that hybridization has occurred between them (see Appendix). The populations of *F. regia* subsp. *serrae* in northern Paraná have exceptionally long sepal tubes, which may be the result of introgression with *F. brevilobis*.

4. **Fuchsia campos-portoi** Pilger & Schulze, Notizbl. Bot. Gart. Berlin-Dahlem 12: 470. 1935; Rodriguésia 2: 94, figs. 1–5. 1935. TYPE: Brazil. Rio de Janeiro: Itatiaia, Serra da Mantiqueira, 2,200 m, 27 Dec. 1934, *Robert Pilger & Curt Brade 31* (holotype, B, destroyed in World War II; lectotype, RB, here designated; isotype, BH). Figure 8.

Subshrubs to woody scandent bushes 0.3–2 (–3) m tall, often growing among rocks. Young growth subglabrous to finely canescent or pilose; older stems 1–4 cm thick, with flaky, coppery brown bark. Leaves mostly ternate, occasionally opposite or 4–5-whorled, firmly membranous, narrowly elliptic-lanceolate, 12–40 mm long, 2–6(–8) mm wide, narrowly acute at the apex, acute to cuneate at the base, dark green and subglabrous above, paler and mostly glabrous below or with villous hairs along veins and margins; margin gland-serrulate, with teeth angled towards the apex, secondary veins 3–7 per side, at times inconspicuous; internodes short, mostly 10–16 mm long. Petioles (2–)3–8 mm long. Stipules 0.5–1 mm long, narrowly lanceolate or filiform, deciduous. Flowers solitary in upper leaf axils; pedicels slender, pendulous, (4–)8–20 mm long. Ovary oblong, 4–5 mm long, ca. 2 mm wide, strigose to strigillose. Floral tube subrhombic, 4–6 mm long, 3.5 mm wide in the middle and ca. 2.5 mm wide at the base and summit, glabrous to strigose outside, glabrous inside; nectary 2.5–3 mm high, shallowly 8-lobed. Sepals 12–20 mm long, lance-elliptic, con-

nate for 3–5 mm at the base; free lobes 4–7 mm wide at base, spreading at anthesis. Tube and sepals red to dark pink. Petals violet, broadly obovate, 9–12 mm long, 7–8 mm wide, rounded to slightly retuse at the apex. Filaments red, 15–28 and 13–25 mm long; anthers purple-red, elliptic-oblong, 1.5–2 mm long, 1–1.5 mm wide. Style glabrous, exserted 5–10 mm beyond the anthers; stigma clavate, 1.2–2 mm long, 0.7–0.9 mm wide. Berry cylindrical-oblong, 14–16 mm long, 7–8 mm thick; seeds 1.3–1.6 mm long, 0.7–1.1 mm wide. Gametic chromosome number $n = 22$.

Distribution (Fig. 5). Endemic to the open campos of the Itatiaia mountain massif, in the Serra da Mantiqueira, Rio de Janeiro and Minas Gerais border, from 2,100 to 2,550 m. Flowers mainly during the summer, from November to March.

Additional specimens examined. BRAZIL. RIO DE JANEIRO: Ayuruoca, *Glaziou 15948* (K, P); Itatiaia (Planalto), *Andrade & Emerich 626* (R); *Aparicio & Edmundo 826* (MO, RB); *Badini 22993* (OUPR); *Berry et al. 4435* (MO, RB; $n = 22$), *4436*, *4438* (MO, RB), *Brade 15160* (R, RB), *15676* (RB, POM, photos at NY, R, UC), *18008* (R, RB, S), *20335* (R); *Campos Porto 2705* (R, RB), *Duarte 826* (US); *Dusén 178* (R); *Gounelle in Jan. 1899* (G—BOIS); *Glaziou 4801* (P), *6522* (K, R); *Hatschbach et al. 35833* (MBM, UC, Z); *Hoehne 11918* (POM); *Koyama et al. 13701* (SP); *Lindeman & de Haas 4120* (MBM, U); *Lobo 4* (R); *Loefgren 5775* (SP); *Lutz in Nov. 1950, in Jan. 1957, in Nov. 1958* (R); *Lutz & Sampaio in Feb. 1954* (R); *Merxmuller 25591* (M); *Pabst 9308* (HB, K, M, MBM); *Pereira 7037* (HB, MBM, PEL); *Pereira & Pereira 7578* (B, HB, R, RB); *Ramamoorthy 104* (MO), *814* (MBM, MO), *s.n.* (MO; $n = 22$); *Santos 5169* (DS); *Sucre 4645* (MO, RB); *Ule 118* (R); *Vianna 771* (R).

Fuchsia campos-portoi is readily distinguished from other fuchsias by its small and very narrow, gland-serrulate leaves. It also has unusual, small flowers; the floral tube is nearly rhombic and very short, whereas the sepals are up to four times as long and are noticeably inflated in bud.

This species inhabits the high-elevation campos of the Itatiaia massif, where it grows in shrubby patches or in open, rocky sites. Winter frosts are common in this area. Populations of *F. regia* subsp. *regia* grow together with *F. campos-portoi*, and several intermediate plants have been found that indicate the occurrence of local hybrids (see Appendix).

5. Fuchsia coccinea Dryander in Aiton, Hort. Kew., 1st edition, 2: 8. 1789. Sims, Bot. Mag. tab. 97. 1789. Mordant de Launay, Herb. Gen. Amat. 2: 89, fig. 1817. Hook., Bot. Mag. 94: tab. 5740. 1868. *Nahusia coccinea* (Dryander) Schneevoogt, Icon. Pl. Rar. 1: 21. 1792. *Fuchsia elegans* Salisbury, Ic. Stirp. Rar., 13, tab. 7. 1791, nom. illeg. (Salisbury thought he would avoid confusion in renaming *F. coccinea*, since all species known at the time had red flowers.) *Fuchsia pendula* Salisbury, Prodr., 279. 1796, nom. illeg. (based on *F. elegans* Salisbury). TYPE: From a plant cultivated in 1788 at Kew Gardens, London, England, "*Oct. 1788, Hort. Kew*" (lectotype, LINN #670.3, Smith Herbarium, here designated: see Fig. 9; isolectotype, BM). Figures 9, 10.

Fuchsia montana Cambessèdes in St. Hilaire, Fl. Brasil. Merid. 2(17): 275, tab. 135. 1830. TYPE: Brazil. Minas Gerais: near the summit of the Serra da Caraça, Dec. 1816–Mar. 1818, *Auguste St. Hilaire B1 449* (holotype, P; isotype, P).

Erect shrubs 0.5–1.5 m tall, or scandent to 7 m high, often with extensive underground stems. Young growth puberulent to densely pilose, older stems 5–20 mm thick, with exfoliating bark. Leaves mostly ternate, sometimes opposite or in 4s, membranous or rarely subcoriaceous, narrowly ovate to ovate, 15–55 mm long, 7–25 mm wide, acute to subacuminate at the apex, subcordate or sometimes rounded at the base, generally dull, light green, paler below, sometimes strongly purple-flushed, subglabrous to puberulent on both sides, but generally densely pilose along the basal ⅓ of the midvein below; margins serrulate or occasionally subentire, secondary veins 4–6 per side. Petioles short and stout, ca. 1 mm thick, 1–3 mm long, occasionally longer on basal leaves, usually densely pilose or hirsute. Stipules narrowly lanceolate, 0.8–1.4 mm long, deciduous. Flowers solitary in the upper leaf axils; pedicels slender, pubescent, 18–42(–50) mm long, divergent or arching from the stems and pendent only in the distal third. Ovary oblong-ellipsoid, 5–9 mm long, 2.5–3 mm thick. Floral tube fusiform, 5–10 mm long, 2.5–3 mm wide at the base, 3.5–4.5 mm wide in the middle and 3–4 mm wide at the top, subglabrous to puberulent outside, puberulent inside; nectary smooth, 2–3 mm high. Sepals 15–24 mm long, oblong-lanceolate, lightly pubescent, connate at the base for 4–7 mm; free lobes 3.5–6 mm wide, acute at the apex, spreading at anthesis. Tube and sepals red to dark pink. Petals violet, obovate, 7–10 mm long, 6–8(–9) mm wide. Filaments red-purple, 18–38 mm and 13–30 mm long; anthers purplish, 2–2.5 mm long, ca. 1.5 mm wide. Style puberulent, red; stigma clavate, 1.5–2 mm long, exserted 5–15 mm beyond the anthers. Mature berry ellipsoid,

14–17 mm long, ca. 12 mm thick, purple; seeds oblong-triangular, 1.4–1.9 mm long, 0.8–1.2 mm wide. Gametic chromosome number $n = 22$.

Distribution (Fig. 5). Occurs in rocky, open campo near the summits of several of the highest mountains in Minas Gerais: Serra da Piedade, Serra da Caraça, Serra do Itacolomi, and Pico do Itambé, from 1,400 to 2,000 m. Flowers throughout the year, mainly from November to March.

Additional specimens examined. BRAZIL. The type sheets of *F. coccinea* are the earliest known specimens of this species, and both were taken from the plant at Kew Gardens upon which Dryander based his description (Hooker, 1869). The source of the plants is unclear; both Sims and

FIGURE 9. Photograph of the lectotype of *Fuchsia coccinea* from the Smith Herbarium at LINN.

Dryander described the species as a native of Chile, introduced to Kew by a Captain Firth. Salisbury (1791), on the other hand, stated that Vandelli introduced the species from Brazil around 1787.

Fuchsia coccinea is a rare species known from just four of the highest mountain ranges in Minas Gerais. It typically grows in rocky, open campo or occasionally in forest patches. It has long been confused in the literature with *F. magellanica*, but *F. coccinea* is easily distinguished by its ovate, subsessile leaves with a conspicuous tuft of long hairs at the base of the lower surface. Its divergent or arching pedicels also differ markedly from the fully pendent flowers of the other species in the section.

Fuchsia regia subsp. *regia* is known to occur sympatrically with *F. coccinea* at the Pico do Itambé and near the summit of the Serra do Itacolomi,

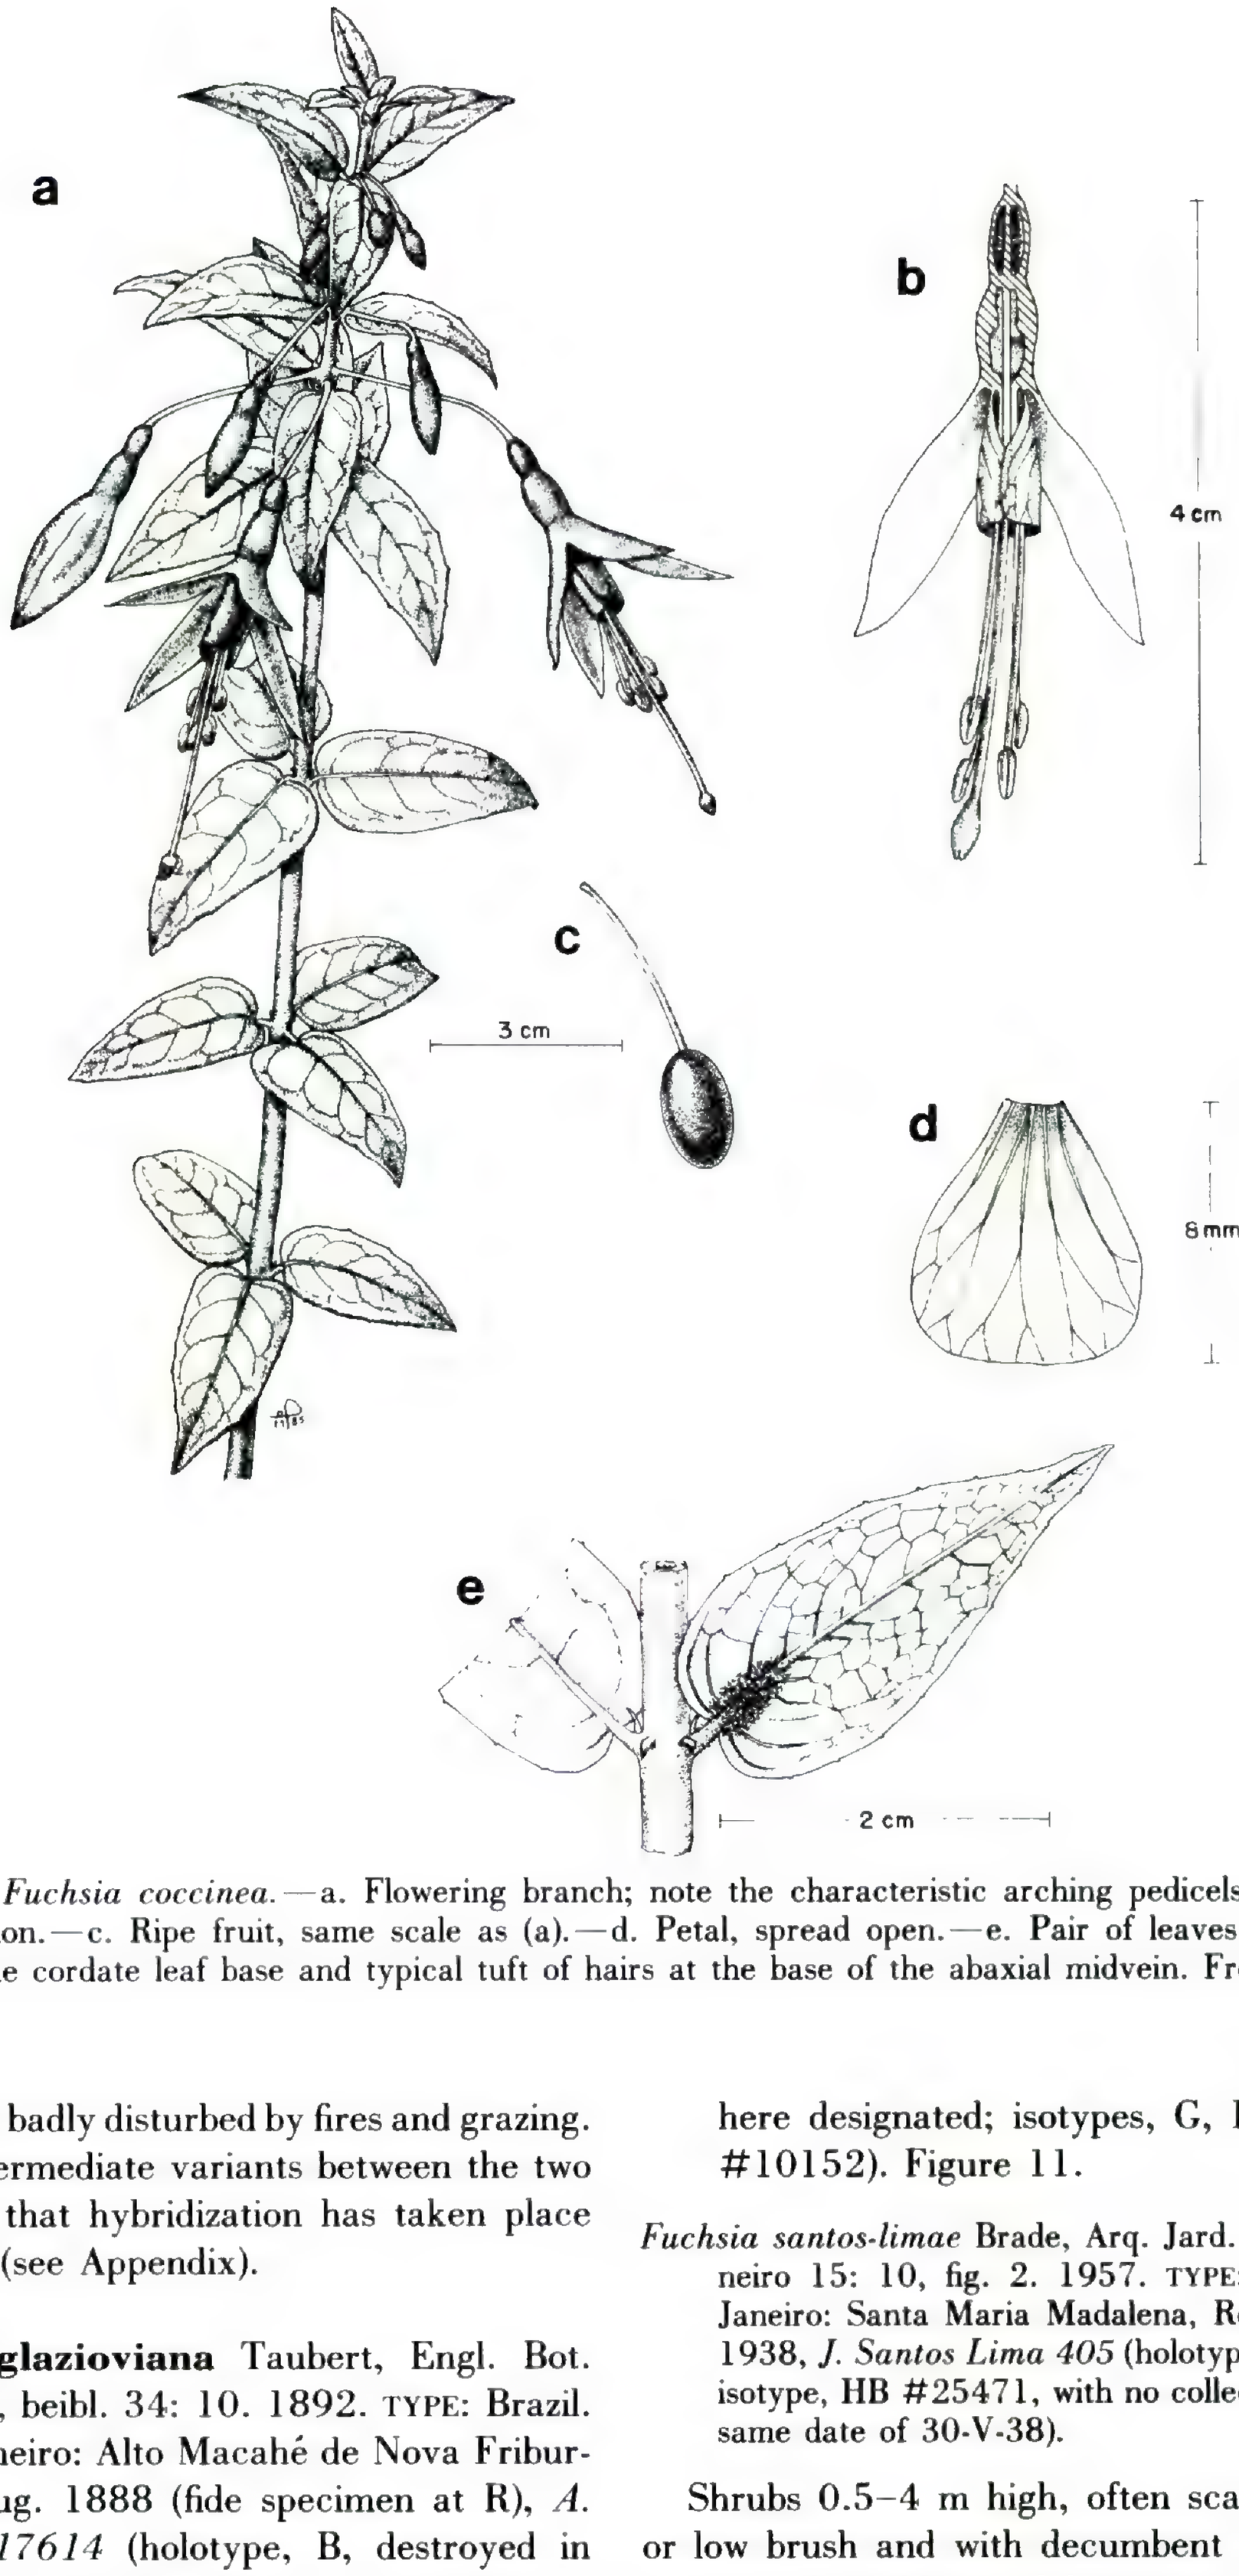

FIGURE 10. *Fuchsia coccinea*.—a. Flowering branch; note the characteristic arching pedicels.—b. Flower in longitudinal section.—c. Ripe fruit, same scale as (a).—d. Petal, spread open.—e. Pair of leaves from the lower stem, showing the cordate leaf base and typical tuft of hairs at the base of the abaxial midvein. From *Berry et al. 4558*.

which has been badly disturbed by fires and grazing. A series of intermediate variants between the two taxa indicates that hybridization has taken place in these areas (see Appendix).

6. Fuchsia glazioviana Taubert, Engl. Bot. Jahrb. 15, beibl. 34: 10. 1892. TYPE: Brazil. Rio de Janeiro: Alto Macahé de Nova Friburgo, 14 Aug. 1888 (fide specimen at R), *A. Glaziou 17614* (holotype, B, destroyed in World War II, photograph at F; lectotype, F, here designated; isotypes, G, LE, LY, P, R #10152). Figure 11.

Fuchsia santos-limae Brade, Arq. Jard. Bot. Rio de Janeiro 15: 10, fig. 2. 1957. TYPE: Brazil. Rio de Janeiro: Santa Maria Madalena, Rochela, 30 May 1938, *J. Santos Lima 405* (holotype, RB #37704; isotype, HB #25471, with no collector number but same date of 30-V-38).

Shrubs 0.5–4 m high, often scandent in trees or low brush and with decumbent branches to 6 m long. Branchlets subdivaricate and generally

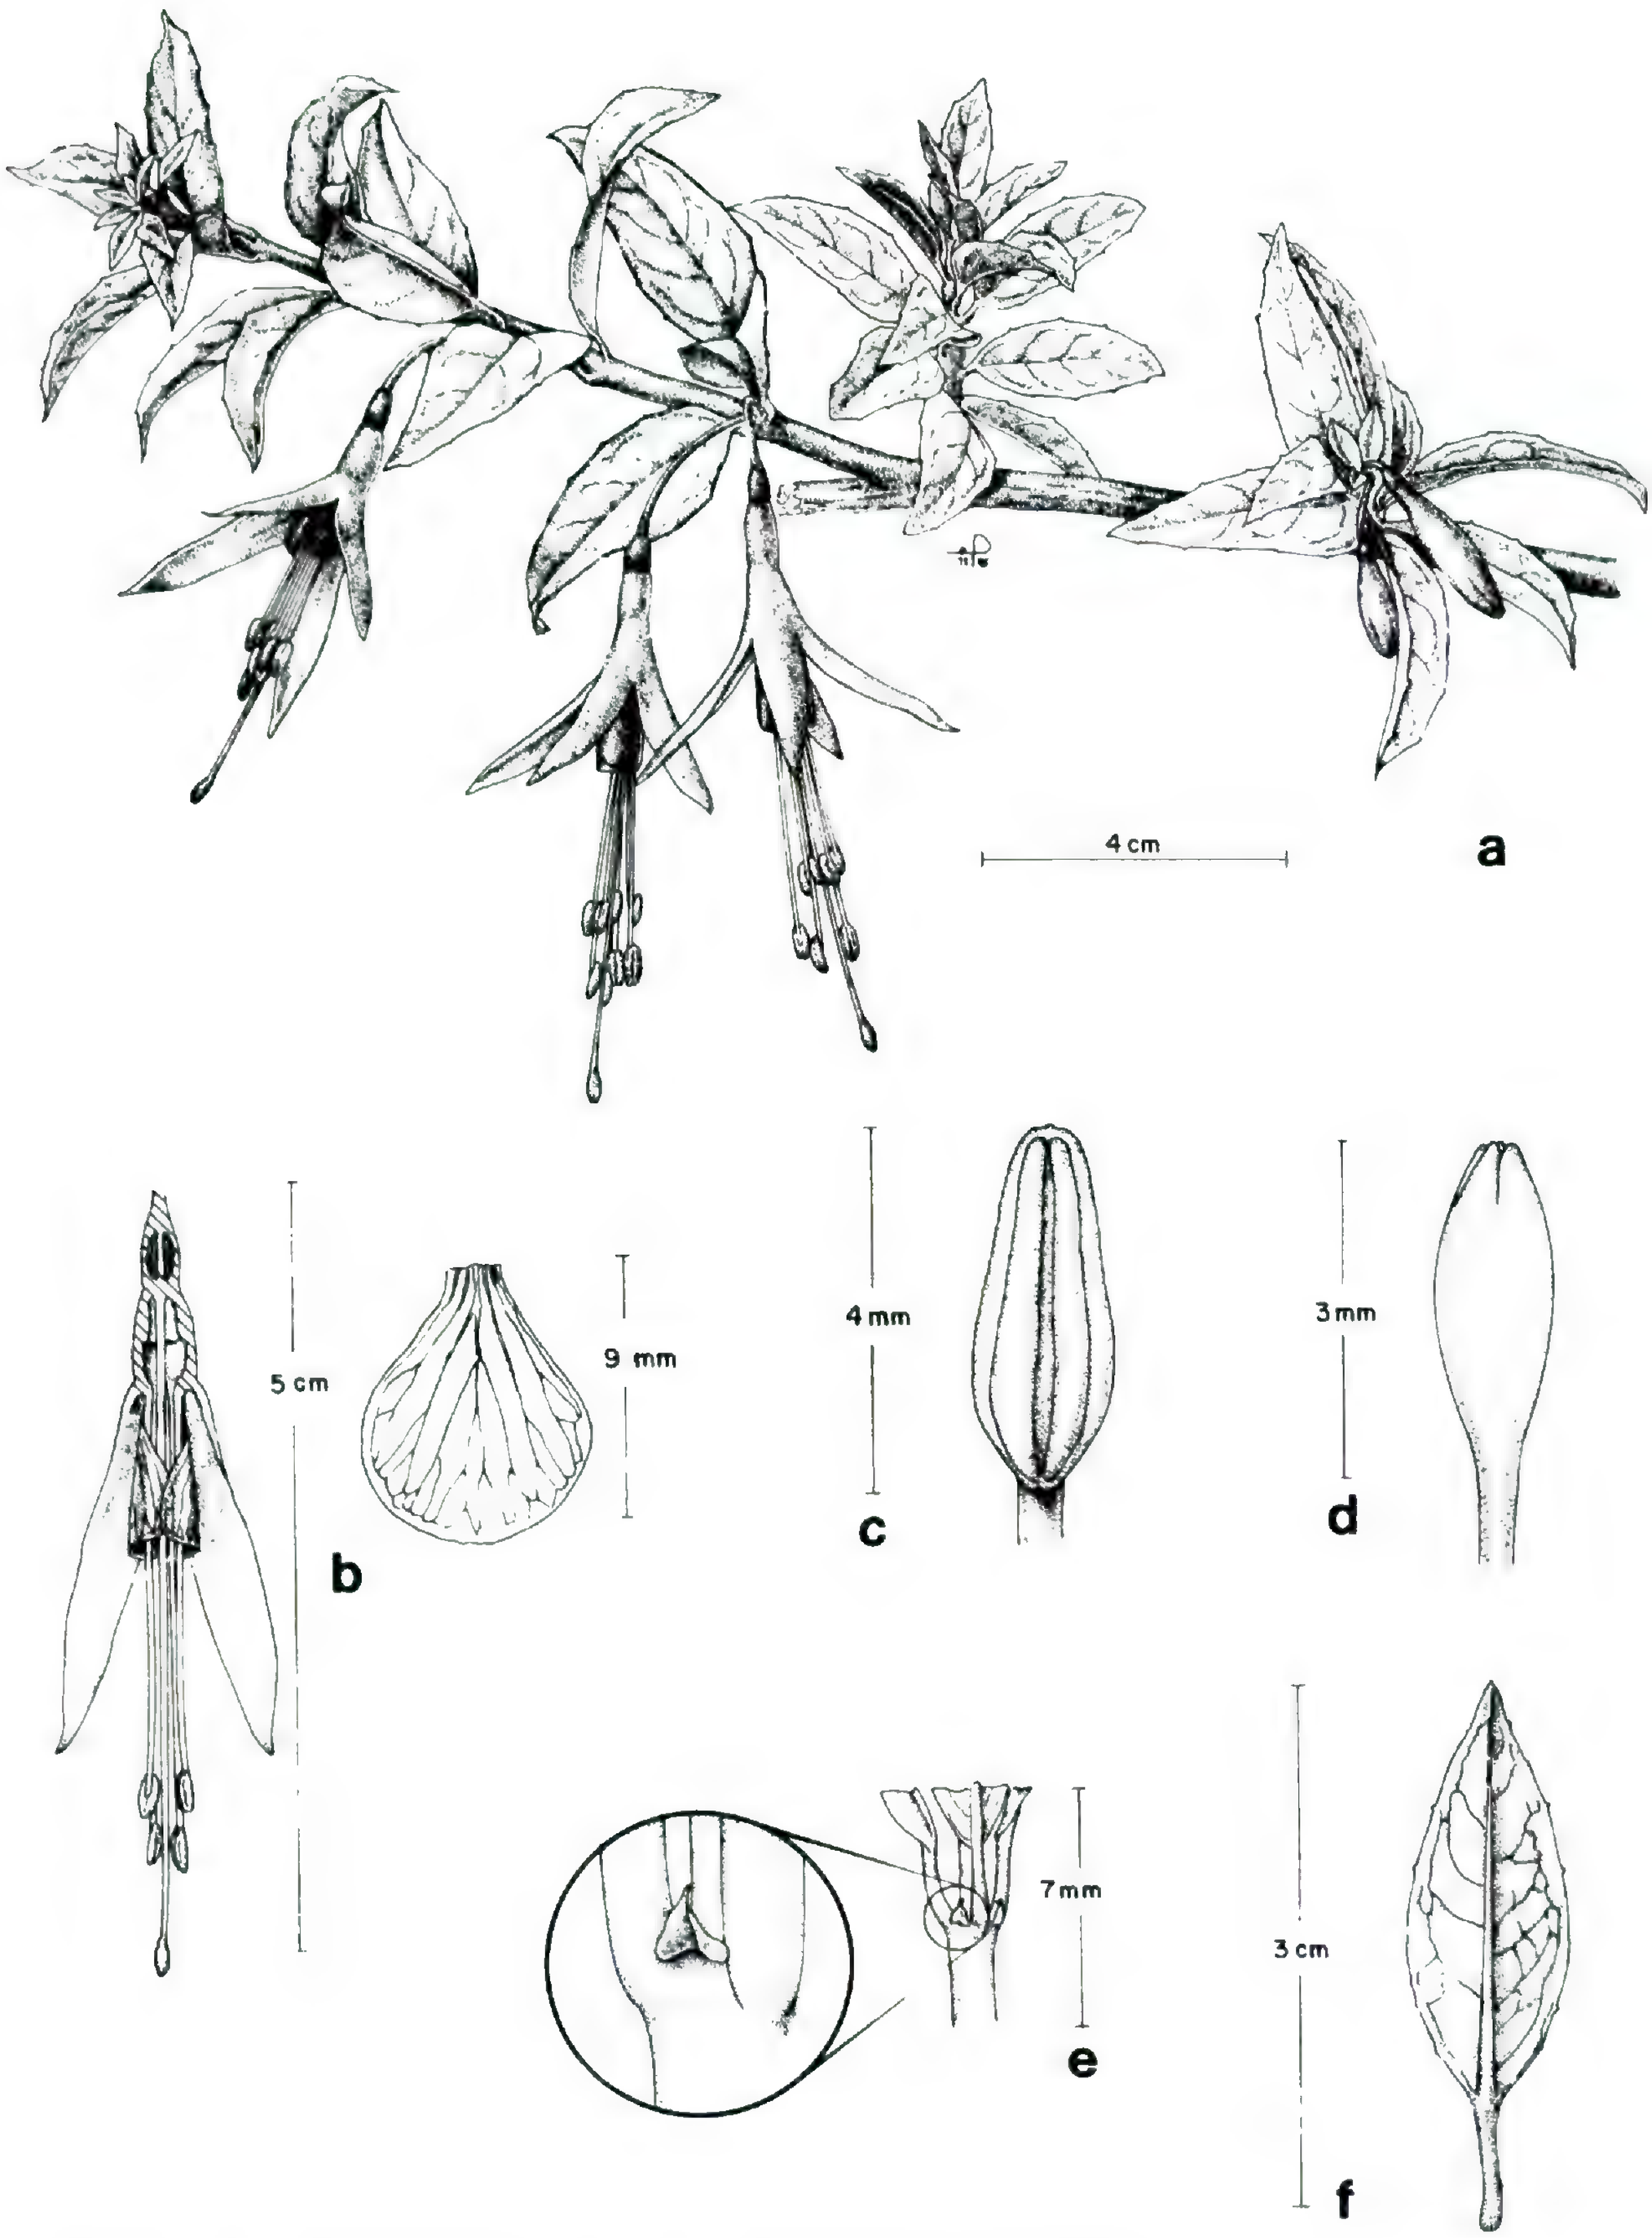

FIGURE 11. *Fuchsia glazioviana.*—a. Flowering branch.—b. Flower in longitudinal section and petal spread open.—c. Detail of anther.—d. Detail of stigma.—e. Detail of stipules.—f. Leaf underside. From *Berry et al. 4422.*

densely packed, minutely puberulent, dull purplish, readily exfoliating. Leaves opposite or ternate, firmly membranous to subcoriaceous, elliptic or lanceolate, 15–30(–40) mm long, 8–15 mm wide, acute at the base and apex, dark sublustrous green and glabrous above, paler and subglabrous below or sometimes pilose at the base of the midvein; margins remotely gland-denticulate, with 4–5(–6) secondary veins per side. Petioles 3–6 mm long, purplish and sparsely puberulent; internodes short, 3–12 mm long. Stipules broadly triangular, 0.6–1.2 mm long and wide, thick at the base, purplish, deciduous. Flowers solitary in the upper leaf axils; pedicels slender, sparsely puberulent, pendulous,

12–26 mm long. Ovary oblong, 4–5 mm long, 2–2.5 mm wide. Floral tube cylindrical, 5–7 mm long, 2.5–4 mm wide, subglabrous outside, glabrous inside; nectary smooth, 3–4 mm high. Sepals 17–22 mm long, narrowly lanceolate, connate at the base for 4–5 mm; free lobes 3–4 mm wide, acuminate at the apex, spreading at anthesis. Tube and sepals red or pink. Petals purple, obovate, 9–12 mm long, 6–9 mm wide, rounded at the apex. Filaments red-purple, 22–32 and 16–28 mm long; anthers oblong, 2.5–3.5 mm long, 1.1–1.6 mm wide. Style red, glabrous to puberulent; stigma clavate, 2–3 mm long and 1–1.4 mm wide, exserted 5–20 mm beyond the anthers. Berry shiny dark purple, subcylindrical, 10–16 mm long, 5–8 mm wide; seeds oblong, 2–4 mm long, 1–1.5 mm wide. Gametic chromosome number $n = 22$.

Distribution (Fig. 5). In open campo and in cloud forest on a few high mountains around the towns of Nova Friburgo and Santa Maria Madalena, in Rio de Janeiro state, from 1,500 to 2,100 m. Flowers throughout the year, mainly from November to March.

Additional specimens examined. BRAZIL. RIO DE JANEIRO: Nova Friburgo, Morro da Nova Caledônia, *Berry et al. 4420* (MO, RB), *4422*, *4423* (MO, RB; $n = 22$), *4426*, *4428*, *4431*, *4434* (MO, RB); *de Lima 530* (RB); *Martinelli et al. 2540* (RB); *Pabst 8134* (HB); Nova Friburgo au fond de la Bocaina do Conejo, *Glaziou 12667* (F, K, LE, LY, P); Nova Friburgo, Morro da torre de TV, *Vianna et al. 789* (MO); Santa Maria Magdalena, Pedra do Desengano, *Farney & Caruso 1190* (RB); *Santos Lima & Brade 13286* (RB, HB #25466, fragment).

Fuchsia glazioviana is distinguished by its small, tightly grouped, shiny, subcoriaceous leaves with short petioles. It is a local endemic known from only two mountains in the Serra do Mar of Rio de Janeiro, where it extends from upper cloud forest into open campo above treeline. On the Morro da Nova Caledônia, it is sympatric with *F. regia* subsp. *regia* in cloud forest habitats, and the two species hybridize locally (see Appendix).

7. Fuchsia hatschbachii P. Berry, sp. nov. TYPE: Brazil. Paraná: Serra São Luiz do Purunã, BR-277, Mun. Campo Largo, 25 Jan. 1985, *P. E. Berry, T. Plowman & F. Juarez 4458* (holotype, MO #3504627; isotype, MBM; $n = 22$). Figure 12.

Frutex erectus vel scandens 1–5 m altus. Folia plerumque opposita, anguste lanceolato-ovata, 3–11 cm longa, 0.8–3 cm lata, apice attenuata vel acuminata basi rotundata vel anguste subcordata, glabra; petiolis 2–6(–7) mm longis, interdum flexis ad basim laminae; stipulis parvis membranaceis 1–1.7 mm longis, 0.6–1.2 mm latis. Tubi florales cylindrici 10–15 mm longi, 3–5 mm lati. Sepala 18–26 mm longa, 3.5–5 mm lata, basi connata 2–6 mm. Petala late obovata 12–17 mm longa, 8–12 mm lata. Numerus gameticus chromosomatum $n = 22$.

Erect to scandent shrubs 1–3 m tall or climbers in trees to 5 m above ground. Branchlets glabrous, dull purple, older branches ascending on small shrubs or decumbent in large or climbing plants. Leaves mostly opposite, occasionally in whorls of 3–4, firmly membranous to subcoriaceous, narrowly lance-ovate, generally 3 times longer than wide, 3.0–7.5(–11.0) cm long, 0.8–2.5(–3.0) cm side, apex attenuate to acuminate, base rounded to narrowly subcordate, sublustrous dark green above, pale below and glabrous on both sides except for small tufts of hairs 0.8–1 mm long at the base of the lower midvein in some plants; margin remotely gland-denticulate, secondary veins 5–6(–7) per side. Petioles wine purple, (2–)3–6(–7) mm long, 1–2 mm thick, canaliculate above, at times making a marked angle at the junction with the midvein. Stipules narrowly triangular, 1–1.7 mm long, 0.6–1.2 mm wide, adjacent ones occasionally fused, semideciduous. Flowers glabrous and solitary in upper leaf axils; pedicels pendulous, (10–)20–30 mm long. Ovary cylindrical, 5–9 mm long, 2.5–3 mm wide. Floral tube cylindrical, 10–15 mm long, 3–5 mm wide; nectary 3–5 mm high. Sepals 18–26 mm long, connate at the base for 2–6 mm; free lobes 3.5–5 mm wide at the base, spreading at anthesis. Tube and sepals red. Petals violet, broadly obovate, 12–17 mm long, 8–12 mm wide. Filaments red, 40–45 mm and 32–40 mm long; anthers red-purple, 3–3.5 mm long, 1–1.5 mm wide. Style red, loosely pilose in lower half; stigma 2–3 mm long, 1–1.5 mm wide, exserted 15–20 mm beyond the anthers. Berry subcylindrical, ± 4-angled, 13–18 mm long, 7–10 mm thick, purple when ripe; seeds oblong-triangular, 1.4–1.8 mm long, 0.8–1.2 mm wide. Gametic chromosome number $n = 22$.

Distribution (Fig. 5). In low forests on limestone or sandstone outcrops, in the planalto north and west of Curitiba, Paraná, between 950 and 1,150 m. Flowers mainly from November to March.

Additional specimens examined. BRAZIL. PARANÁ: Serra São Luiz do Purunã, BR-277, Mun. Campo Largo, *Berry et al. 4459* (MBM, MO; $n = 22$), *4460*, (MBM, MO), *4461* (MBM, MO; $n = 22$), *4462*, *4463*, *4464*, *4465* (MBM, MO); *Brade 19494* (RB); *Frenzel in 28 Feb. 1951* (MBM #6372, MBM #75197); *Hatschbach 7541* (MBM); *Hatschbach & Oliveira 42962* (MBM); *Hatschbach et al. 42960*, *42964* (MBM); *Kummrow 1512*, *2217* (MBM); *Pereira 5193* (F, HB, MB, MO, RB); Sprea, Mun. Rio Branco do Sul, *Hatschbach 7774* (MBM); Serra do Caete, *Hatschbach 40698* (MBM); Mun. Palmeira, BR-277, Rio Papagaio, *Hatschbach 50824* (MBM).

Fuchsia hatschbachii is most likely to be confused with *F. regia* but differs by having shorter petioles, narrow leaves with somewhat curved petioles, shortly connate sepals, and small stipules. It is tetraploid, whereas all examined populations of *F. regia* from Paraná are octoploid. *Fuchsia hatschbachii* grows within 20 km of populations of *F. regia* subsp. *serrae* and *F. brevilobis* but occurs in drier, more interior areas of the planalto and is unusual in its close association with limestone or sometimes sandstone outcrops. The species is dedicated to Gert Hatschbach, Director of the Museu Botânico Municipal de Curitiba, who has done more than any previous botanist to collect and study the flora of Paraná.

8. Fuchsia magellanica Lamarck, Encycl. 2: 565. 1788; Tabl. encycl. 1, Volume 2(1): pl. 282. 1792. *Fuchsia magellanica* var. *typica* Munz, Proc. Calif. Acad. Sci. IV. 25: 9. 1943. *Fuchsia coccinea* Dryander var. *robustior* Hooker, Bot. Antarc. Voy.: 269. 1847, pro parte. TYPE: Chile. Straits of Magellan, Jan. 1768, *Philibert Commerson* (holotype, P—Lamarck Herbarium, also on microfiche; isotypes, BM, P—Jussieu Herb., LINN). Figure 13.

Fuchsia macrostema Ruiz & Pavón, Fl. Peruv. Chil. 3: 88, pl. 324, fig. b. 1802. *Fuchsia macrostema* Ruiz & Pavón var. *grandiflora* Hooker, Bot. Misc. 3: 308. 1833. *Fuchsia gracilis* var. *macrostema* (Ruiz & Pavón) Lindley, Bot. Reg. 13: pl. 1052, 1827. *Fuchsia coccinea* Dryander var. *macrostema* (Ruiz & Pavón) Hooker, Bot. Antarc. Voy.: 270. 1847. *Fuchsia magellanica* var. *macrostema* (Ruiz & Pavón) Munz, Proc. Calif. Acad. Sci. IV. 25: 9. 1943. TYPE: Chile: VIII Región (Bío-Bío), Concepción, Quebrada de Carcamo, 1778–1788, *Hipólito Ruiz & José Pavón* (lectotype, MA, here designated).

Thilcum tinctorium Molina, Saggio Chili, 2nd edition: 146, 286. 1810. LECTOTYPE: plate 47 of *Thilco* Feuillée in J. Observ. Phys. Math. Bot. (Hist. Plantes Medicinales). 1725 here designated. (Feuillée described *Thilco* with five-merous flowers, which Molina thought worthy of generic recognition.)

Fuchsia gracilis Lindley, Bot. Reg. 10: pl. 847. 1824. *Fuchsia magellanica* var. *gracilis* (Lindley) Bailey, Cyclop. Amer. Hort., 614. 1900. TYPE: cultivated in Walton, England, *John Lindley in 1824* (holotype, CGE). First illustrated in Bot. Mag. 2507. 1824, where it was erroneously identified by Graham as *Fuchsia decussata* Ruiz & Pavón.

Fuchsia conica Lindley, Bot. Reg., t. 1062. 1827. *Fuchsia macrostemma* var. *conica* (Lindley) Sweet, Brit. Fl. Gard. 6: pl. 216. 1833. *Fuchsia magellanica* var. *conica* (Lindley) Bailey, Cyclop. Amer. Hort., 614. 1900. TYPE: cultivated in London, England in 1826, from seeds sent from Chile in 1824, *John Lindley* (not seen).

Fuchsia gracilis var. *multiflora* Lindley, Bot. Reg. 13: pl. 1052. 1827. TYPE: cultivated at the Horticultural Society, London, England, 1826, from Chilean seeds introduced in 1824, *John Lindley s.n.* (holotype, CGE; isotype, K).

Fuchsia discolor Lindley, Bot. Reg., pl. 1805. 1835. *Fuchsia magellanica* var. *discolor* (Lindley) Bailey, Cyclop. Amer. Hort., 614. 1900. TYPE: cultivated at the Horticultural Society, London, England, from plants growing in Port Famine in the Magellan Straits, *John Lindley s.n.* (holotype, CGE).

Fuchsia chonotica R. A. Philippi, Linnaea 28: 687. 1856. *Fuchsia coccinea* Solander var. *chonotica* (R. A. Philippi) Reiche, Anales Univ. Chile 98: 485. 1897. TYPE: Chile: X Región (Los Lagos), Chiloé, Archipiélago de Huaytecas, 6 Mar. 1857, *F. Fonk 153a* (lectotype, SGO #53136, here designated). The lectotype is mounted on the same sheet with *Fonk 153b*, collected on 8-III-1857 from Puerto Low, Chiloé.

Fuchsia araucana F. Philippi in R. A. Philippi. Bot. Zeit. 34: 577, t. 9, fig. 6. 1876. TYPE: Chile: IX Región (Araucanía), Prov. Cautín, Toltén, Feb. 1875, *F. Philippi s.n.* (holotype, SGO #53139).

Fuchsia magellanica var. *molinae* Espinosa, Bol. Mus. Nac. Chile 12: 102. 1929. TYPE: Chile, X Región (Los Lagos), Chiloé, quebrada de La Chacra, near Castro, 31 Jan. 1929, *Espinosa s.n.* (holotype, SGO #53152; isotype, SGO #53121).

Fuchsia magellanica var. *eburnea* Pisano, Ans. Inst. Pat. (Chile) 10: 155. 1979. TYPE: Chile: XII Región (Magallanes), Isla Englefield, Seno Otway, 53°05′S, 71°51′W, 26 Feb. 1979, *Edmundo Pisano & R. Cárdenas 4947* (holotype, HIP #6892; isotypes, MO, RNG, SGO #95030).

Erect to semiscandent shrubs 0.5–3(–5) m tall. Branchlets tan to reddish, glabrous or occasionally sparsely strigillose with appressed hairs 0.3–0.4 mm long; older stems with tan, flaky bark, up to 25 cm diam. at the base. Leaves opposite, ternate or occasionally quaternate, membranous, (narrowly) elliptic-ovate, 15–55(–70) mm long, 5–25(–40) mm wide, acute to acuminate at the apex, mostly obtuse at the base, glabrous to strigillose along veins on both sides, paler below and sometimes with reddish veins; margin serrulate or crenate-dentate,

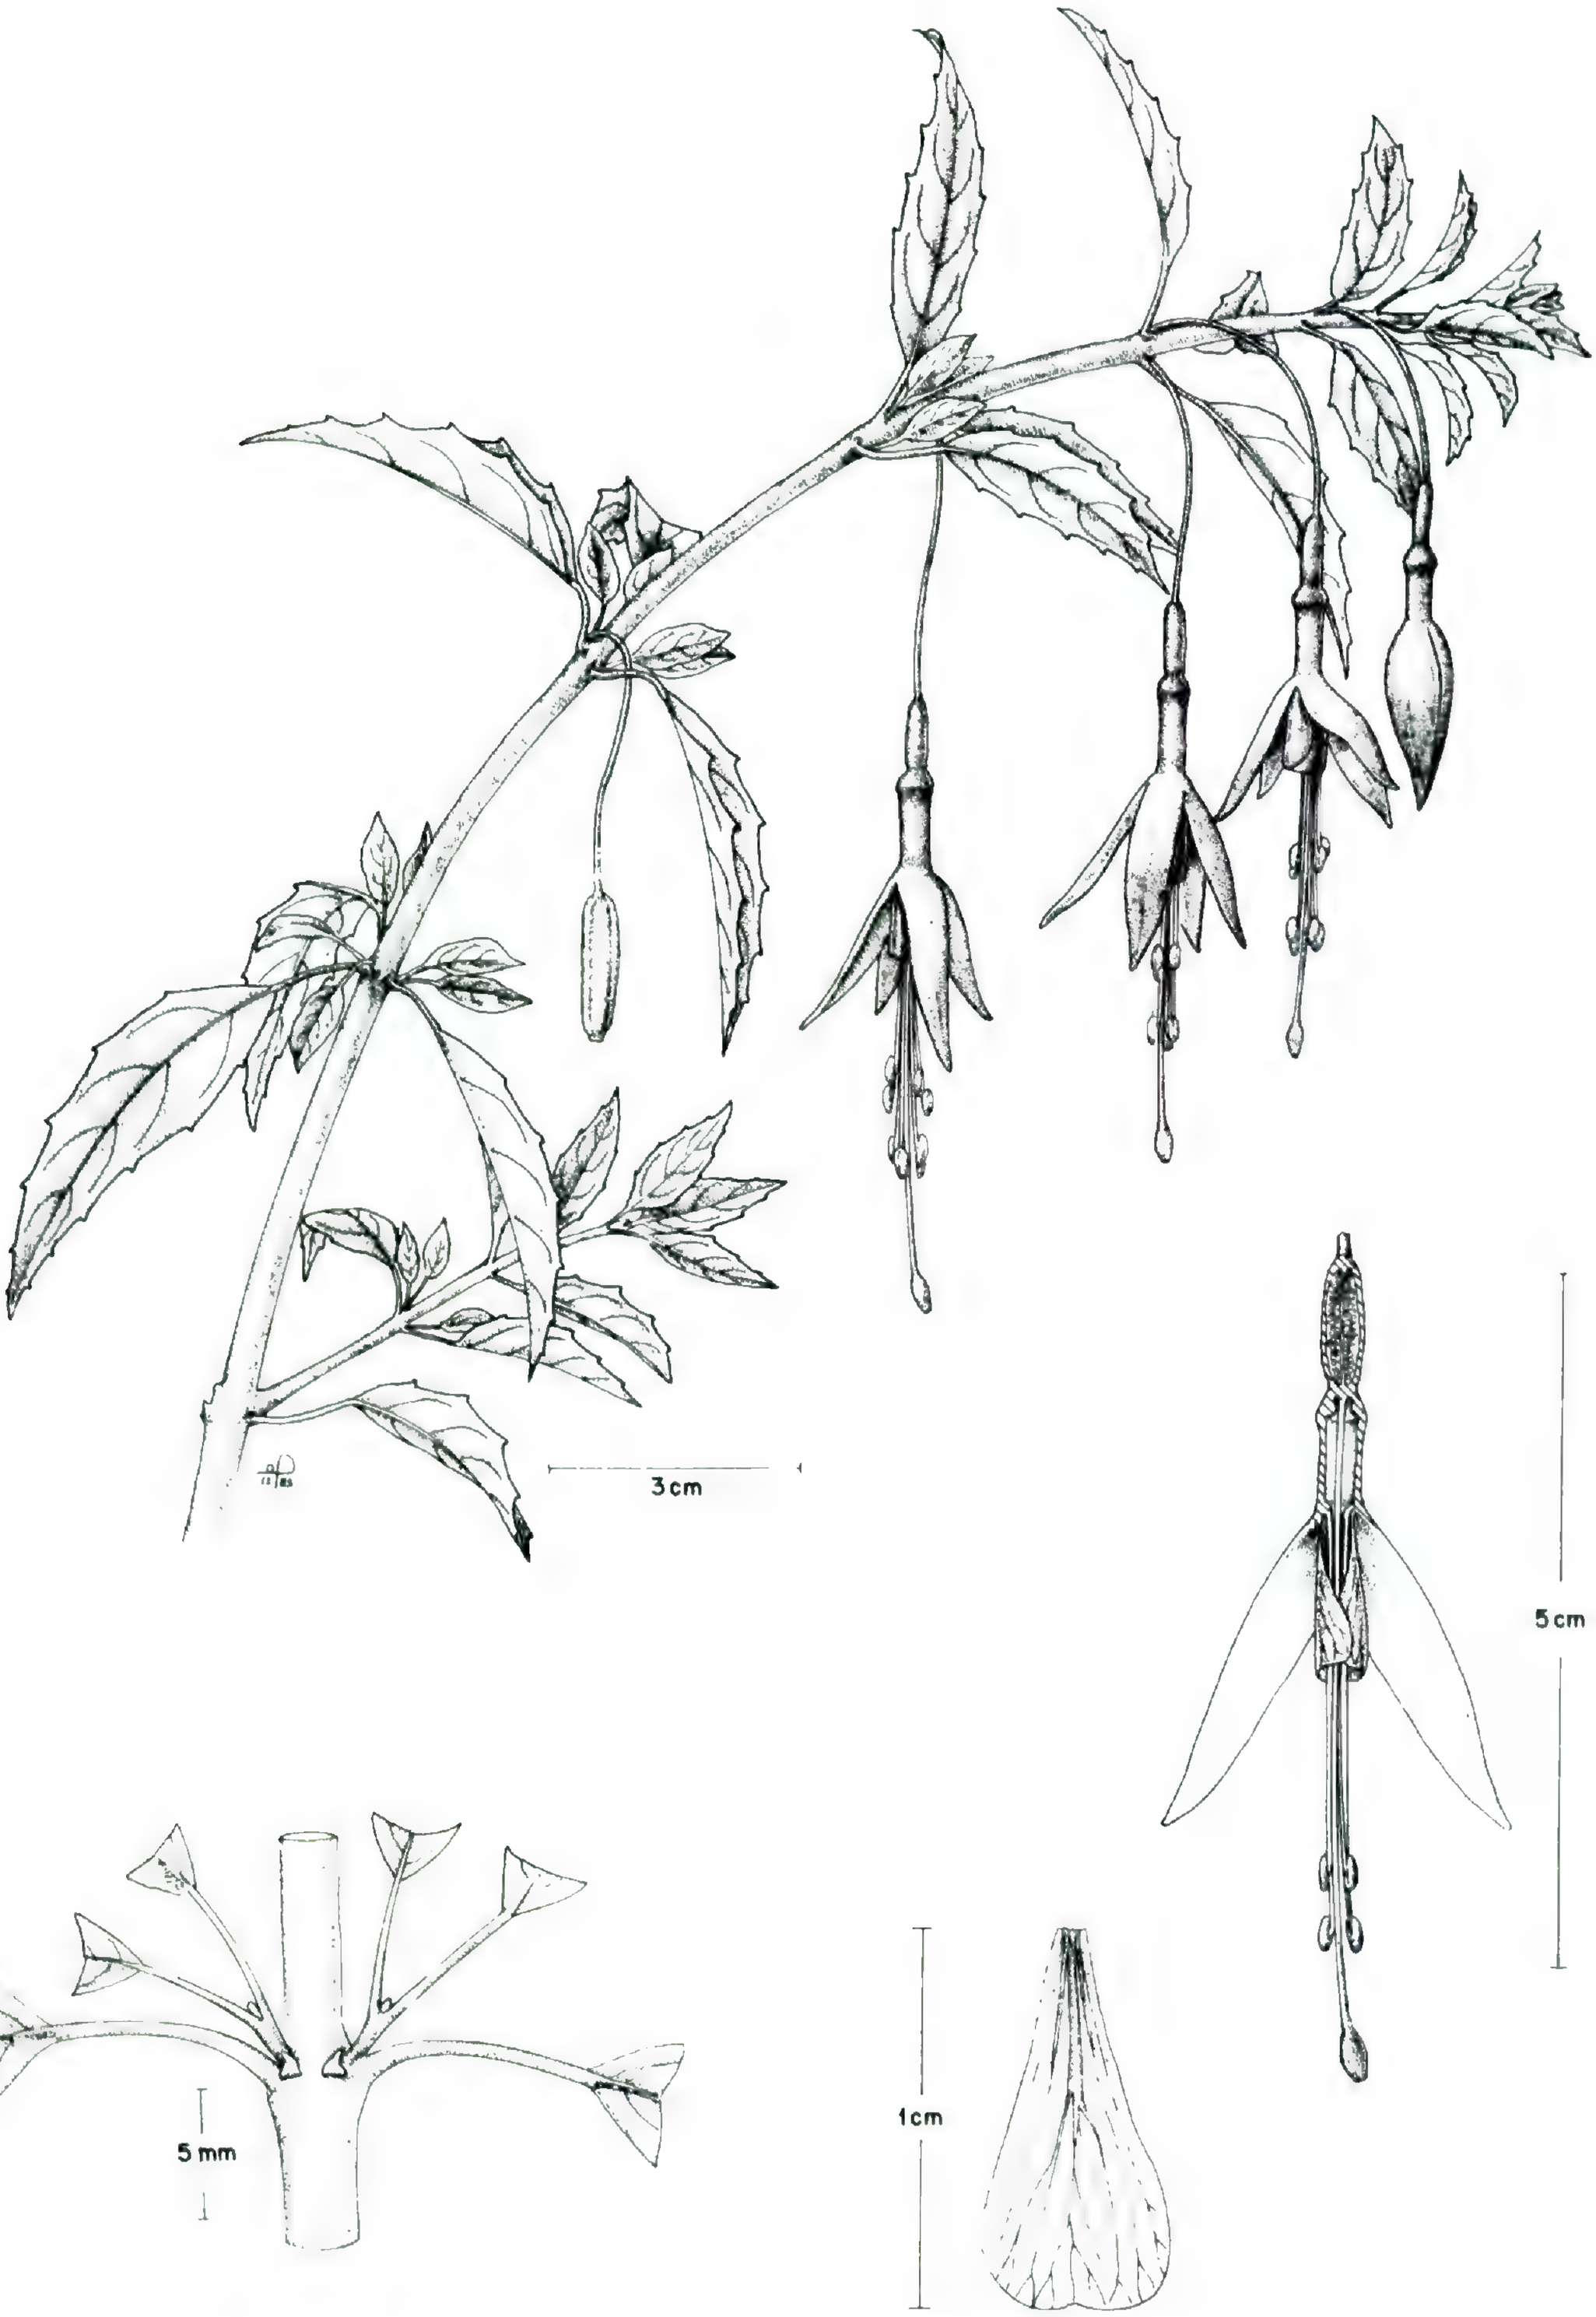

FIGURE 13. *Fuchsia magellanica*. Flowering branch, longitudinally split flower, individual petal spread open, and detail of stem with stipules and petioles. From *Solomon & Solomon 4599*.

veins; margin serrulate or crenate-dentate, often shallowly lobed between the teeth, secondary veins 4–7 per side. Petioles slender, 0.3–1 mm thick, 3–20 mm long. Stipules (narrowly) lanceolate, 0.7–1.3 mm long, 0.5–0.8 mm wide, deciduous. Flowers solitary or rarely in pairs in upper leaf axils; pedicels filiform, pendulous, (13–)20–55 mm long, glabrous to strigillose. Ovary (narrowly) oblong,

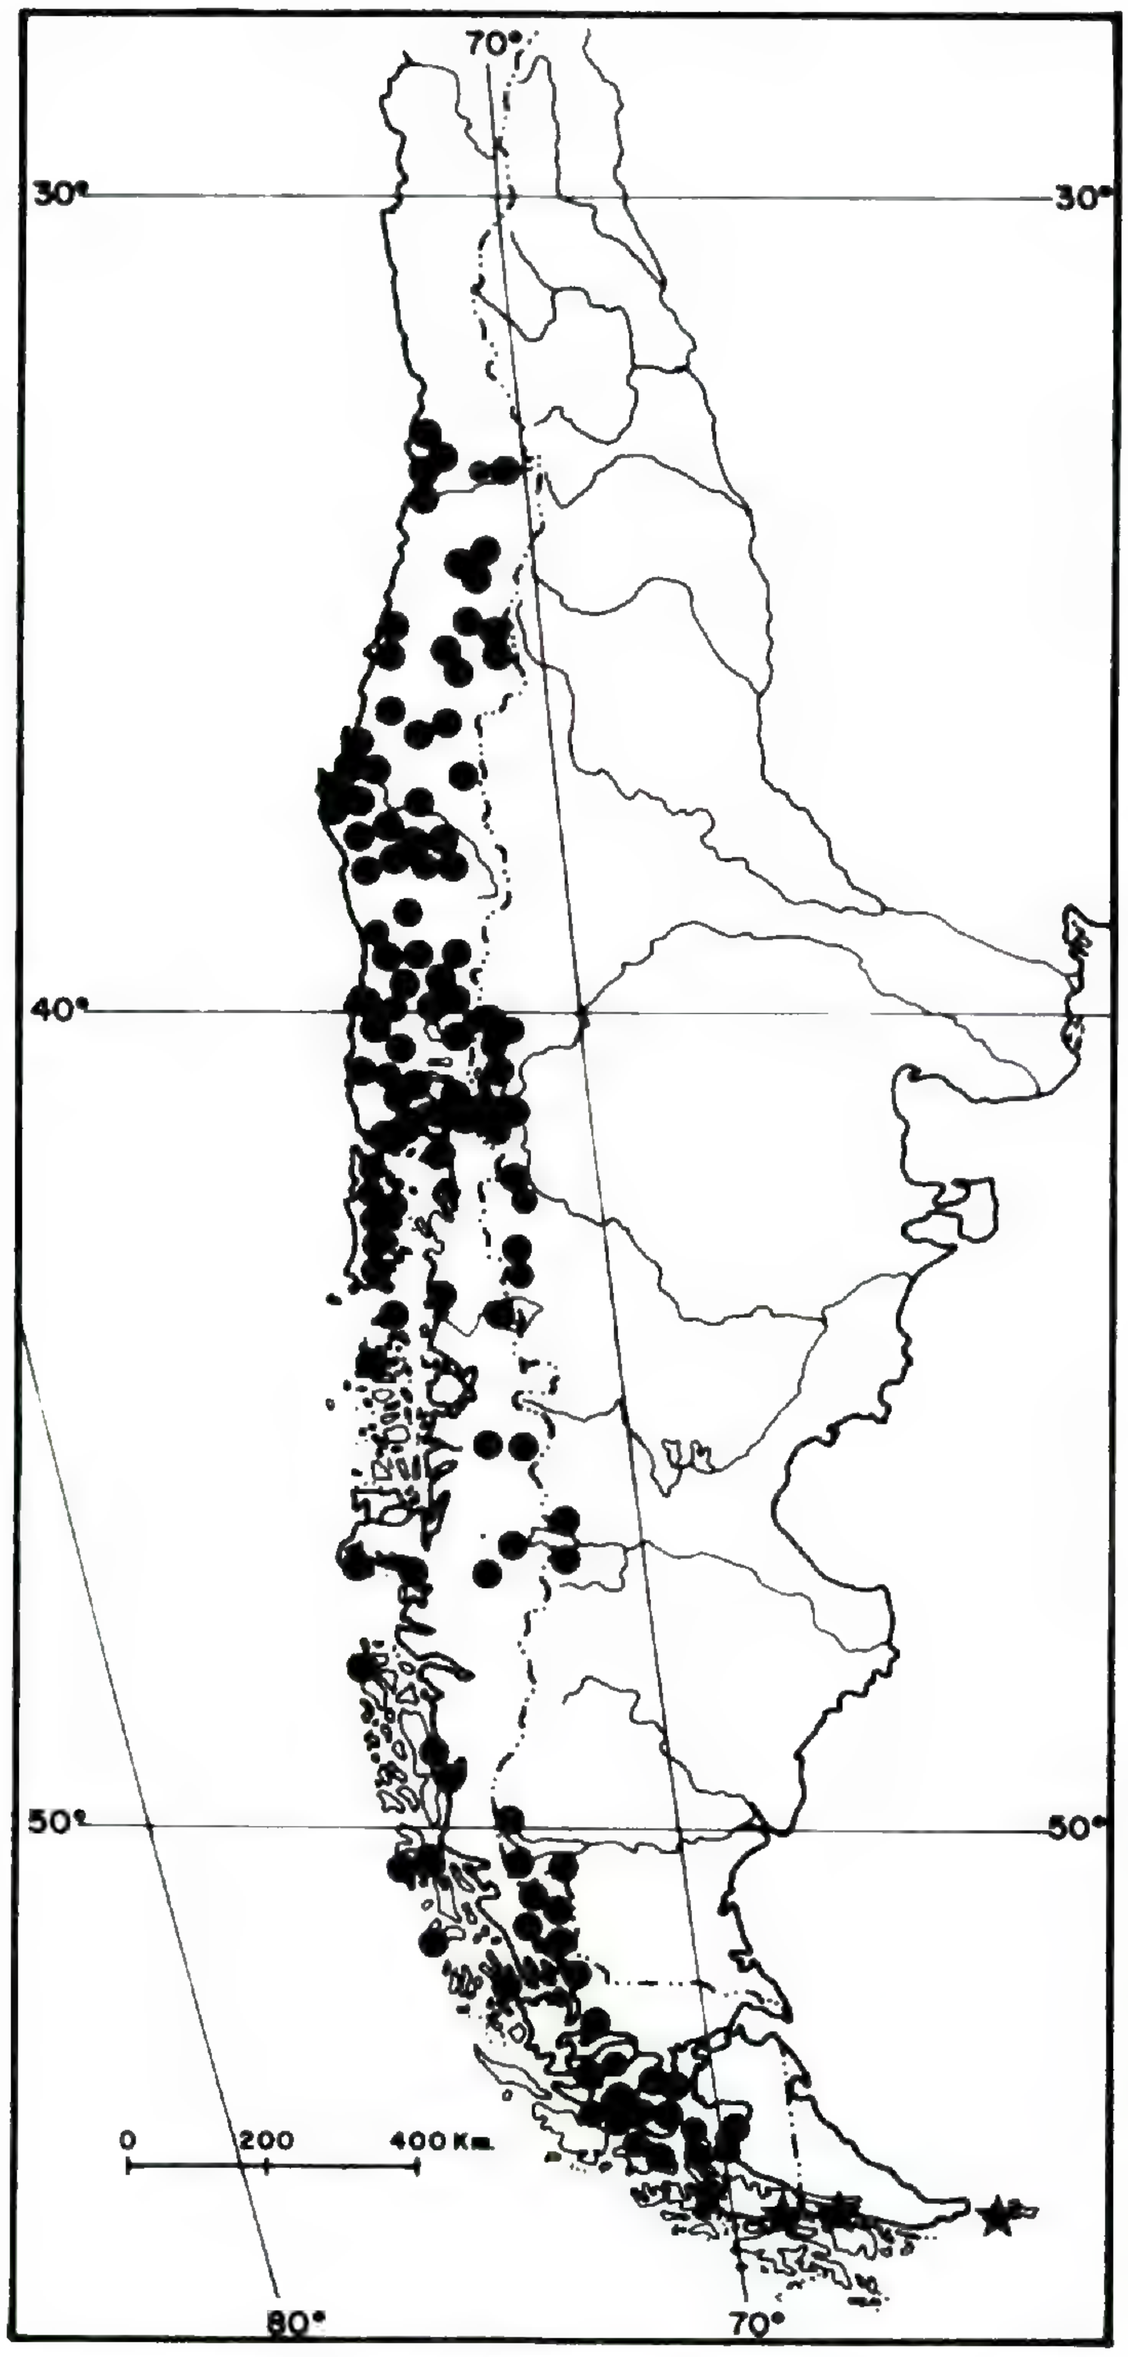

FIGURE 14. Native distribution of *Fuchsia magellanica*. Stars indicate collections made in the early 19th century from populations that have since been eliminated.

(5–)7–11(–14) mm long, 2–3 mm wide. Floral tube cylindrical to narrowly obconic, 7–15 mm long, 2–3.5 mm wide, glabrous to strigillose outside, pilulose inside; nectary 1.8–3 mm high, irregularly lobed. Sepals (15–)17–25(–30) mm long, narrowly lanceolate, connate at the base for 2–5 mm; free lobes (3–)4.5–7(–8) mm wide at base, acuminate at the apex, spreading at anthesis. Tube and sepals generally crimson, rarely pale whitish pink. Petals purple or rarely pale pink, narrowly obovate, (8–)11–20 mm long, 5–11 mm wide, apex rounded. Filaments red-purple, (18–)22–35 mm and (11–)19–31 mm long; anthers purplish, oblong, 2.5–3.5 mm long, 1–2 mm wide. Style purple-red, pubescent at the base; stigma clavate, purple-red, 2–3 mm long, 1–2 mm wide. Berry narrowly oblong, (10–)15–22 mm long, 4–7 mm thick; seeds irregularly oblong-triangular, 1.0–1.4 mm long, 0.7–0.9 mm wide. Gametic chromosome number $n = 22$.

Distribution (Fig. 14). In moist scrub and along forest margins or in clearings, usually near water. Throughout the central and southern Andes of Chile and Argentina and in coastal Chile; from Valparaíso, Chile (32°50′S) and Neuquén, Argentina (39°30′S) to southern Tierra del Fuego (55°S). From sea level (throughout the range) to 1,750 m in central Chile near Santiago. Flowering principally from December to March, occasionally as early as October and as late as April. Widely cultivated throughout the world and naturalized in parts of South America, east Africa, New Zealand, Ireland, and Hawaii.

Fuchsia magellanica is separated from the Brazilian members of section *Quelusia* by 1,000–1,500 km. Yet it is remarkably similar to those species morphologically and can be best distinguished by its elongated ovary and fruit, relatively long petioles (usually over ¼ the length of the blade), and more dentate leaf margins, which are sometimes shallowly lobed between the teeth. *Fuchsia magellanica* lacks the long, drooping branches of some of the lianoid species from Brazil, and it generally grows as an upright shrub. In cultivation it can also reach treelike proportions and is considered the hardiest (most frost-resistant) of all *Fuchsia* species.

A number of different species and varieties have been recognized by others for what is considered here to be a monotypic species. Two different color varieties have been named for plants that lack the typical red coloration of the floral tube, sepals, leaf

veins, and petioles. One, *F. magellanica* var. *molinae*, comes from the island of Chiloé; the other, *F. magellanica* var. *eburnea*, is from the southern Magallanes Region of Chile. Similarly pale-colored plants are also known from Corral, Prov. Valdivia, Chile (*Gunkel 2133*, GH). All of these plants occur sympatrically with red-flowered populations of *F. magellanica* and probably result from minor recurring mutations on pigmentation.

Munz (1943: 9) thought that plants from the southern part of the range, which he called *F. magellanica* var. *typica*, had consistently smaller leaves and flowers than those from the north, but this is clearly not the case. Large-leaved plants occur throughout the range of the species. James Solomon (pers. comm.) examined many local populations in Chile and Argentina and found that individuals growing in the sun usually have smaller leaves and flowers than those nearby in shadier sites. Similarly, clines in leaf size and texture occur along climatic gradients, such as that along the shores of Lago Nahuel Haupi in Argentina. The vegetation in that area becomes increasingly xeric from west to east, and plants of *F. magellanica* respond to this gradient by developing lower, more compact plants with smaller, thicker leaves.

Populations of plants with small, densely packed leaves are common on the island of Chiloé, where high levels of humidity predominate throughout the year. Larger-leaved individuals also occur together with these variants. Some of the phenotypic variants of *F. magellanica* may also be genetically determined, as they are known to maintain their distinctive characteristics under uniform growing conditions. In horticultural circles, there has been a strong tendency to assign varietal names to some of these strains.

In this treatment, I am not recognizing any varietal or subspecific taxa under *F. magellanica*, because it is apparent that a great deal of local variation exists over the broad geographical range of the species, without any clear geographical correlations. The species is cytologically uniform, with over 40 populations counted with $2n = 44$. Since most of the present range of the species, south of 44°S latitude, was completely glaciated during the major glacial advances of the Pleistocene (Vuilleumier, 1971), there has probably been very little time for populations to diverge in the southern part of the range.

In his *Flora of Tierra del Fuego*, Moore (1983) cited localities of *F. magellanica* from as far south as the Beagle Channel at 55°S, and west to Staten Island, at 64°W. Collections from these areas were made in the past century, however, and it is unlikely that the species occurs there naturally today. According to D. Moore (pers. comm.), the introduction of goats on Staten Island early in the last century and the activities of Europeans in the vicinity of the Beagle Channel during the past 100 years have badly deteriorated the woody vegetation of these areas.

On the drier, Argentinian side of the Andean Cordillera, *F. magellanica* occurs natively as far north as the Lago Quillén, at 39°30′S. Northwards, the mountains become increasingly arid. On the Pacific side of the Andes, native populations are found as far north as Concón (32°50′S), just north of Valparaíso. These populations grow close to the coast, along streams in wooded ravines. Looser (1928) found native populations of *F. magellanica* east of Santiago (33°30′S), in the Quebrada de Peñalolén, between 1,450 and 1,750 m, and Navas (1976) reported the species from the nearby Quebrada de Macul.

The northernmost extension of *Fuchsia magellanica* barely overlaps with the southernmost populations of the xeromorphic *F. lycioides* (sect. *Kierschlegeria*) in the vicinity of Concón, north of Valparaíso, Chile. A number of specimens collected in this area during the last century are morphologically intermediate between the two species and may represent interspecific hybrids (see Appendix).

9. Fuchsia regia (Vellozo) Munz, Proc. Calif. Acad. Sci. IV. 25: 13, pl. 1, fig. 5, 1943. *Quelusia regia* Vellozo, Fl. Flum. 149. 1829; Icon. 4: tab. 6. 1831. LECTOTYPE: The illustration in Tab. 6, Volume 4 of the *Icones* of *Flora Fluminensis*. Vellozo stated for the type locality: "in the Pharmacopolitan Alps on the way to the town of Cunha," which is located between Paraty and Cunha, in the Serra da Bocaina, near the São Paulo–Rio de Janeiro border, Brazil. According to Borgmeier (1937), Vellozo collected in this area between 1779 and 1787, and the original illustrations were made in the field from live plants.

Erect to generally scandent or climbing shrubs 0.5–5 m tall, or lianas up to 15 m high in trees. Branchlets wine purple, glabrous to puberulent, rarely densely pilose; main branches ascending in small plants, decumbent to drooping and 1–6 m long in large ones. Leaves opposite, or in whorls of 3, 4, or rarely 5, firmly membranous to coriaceous, (narrowly) elliptic-ovate to ovate, 20–140 mm long, 8–70 mm wide, apex acute to acuminate, base acute to rounded, glabrous to pilose on both

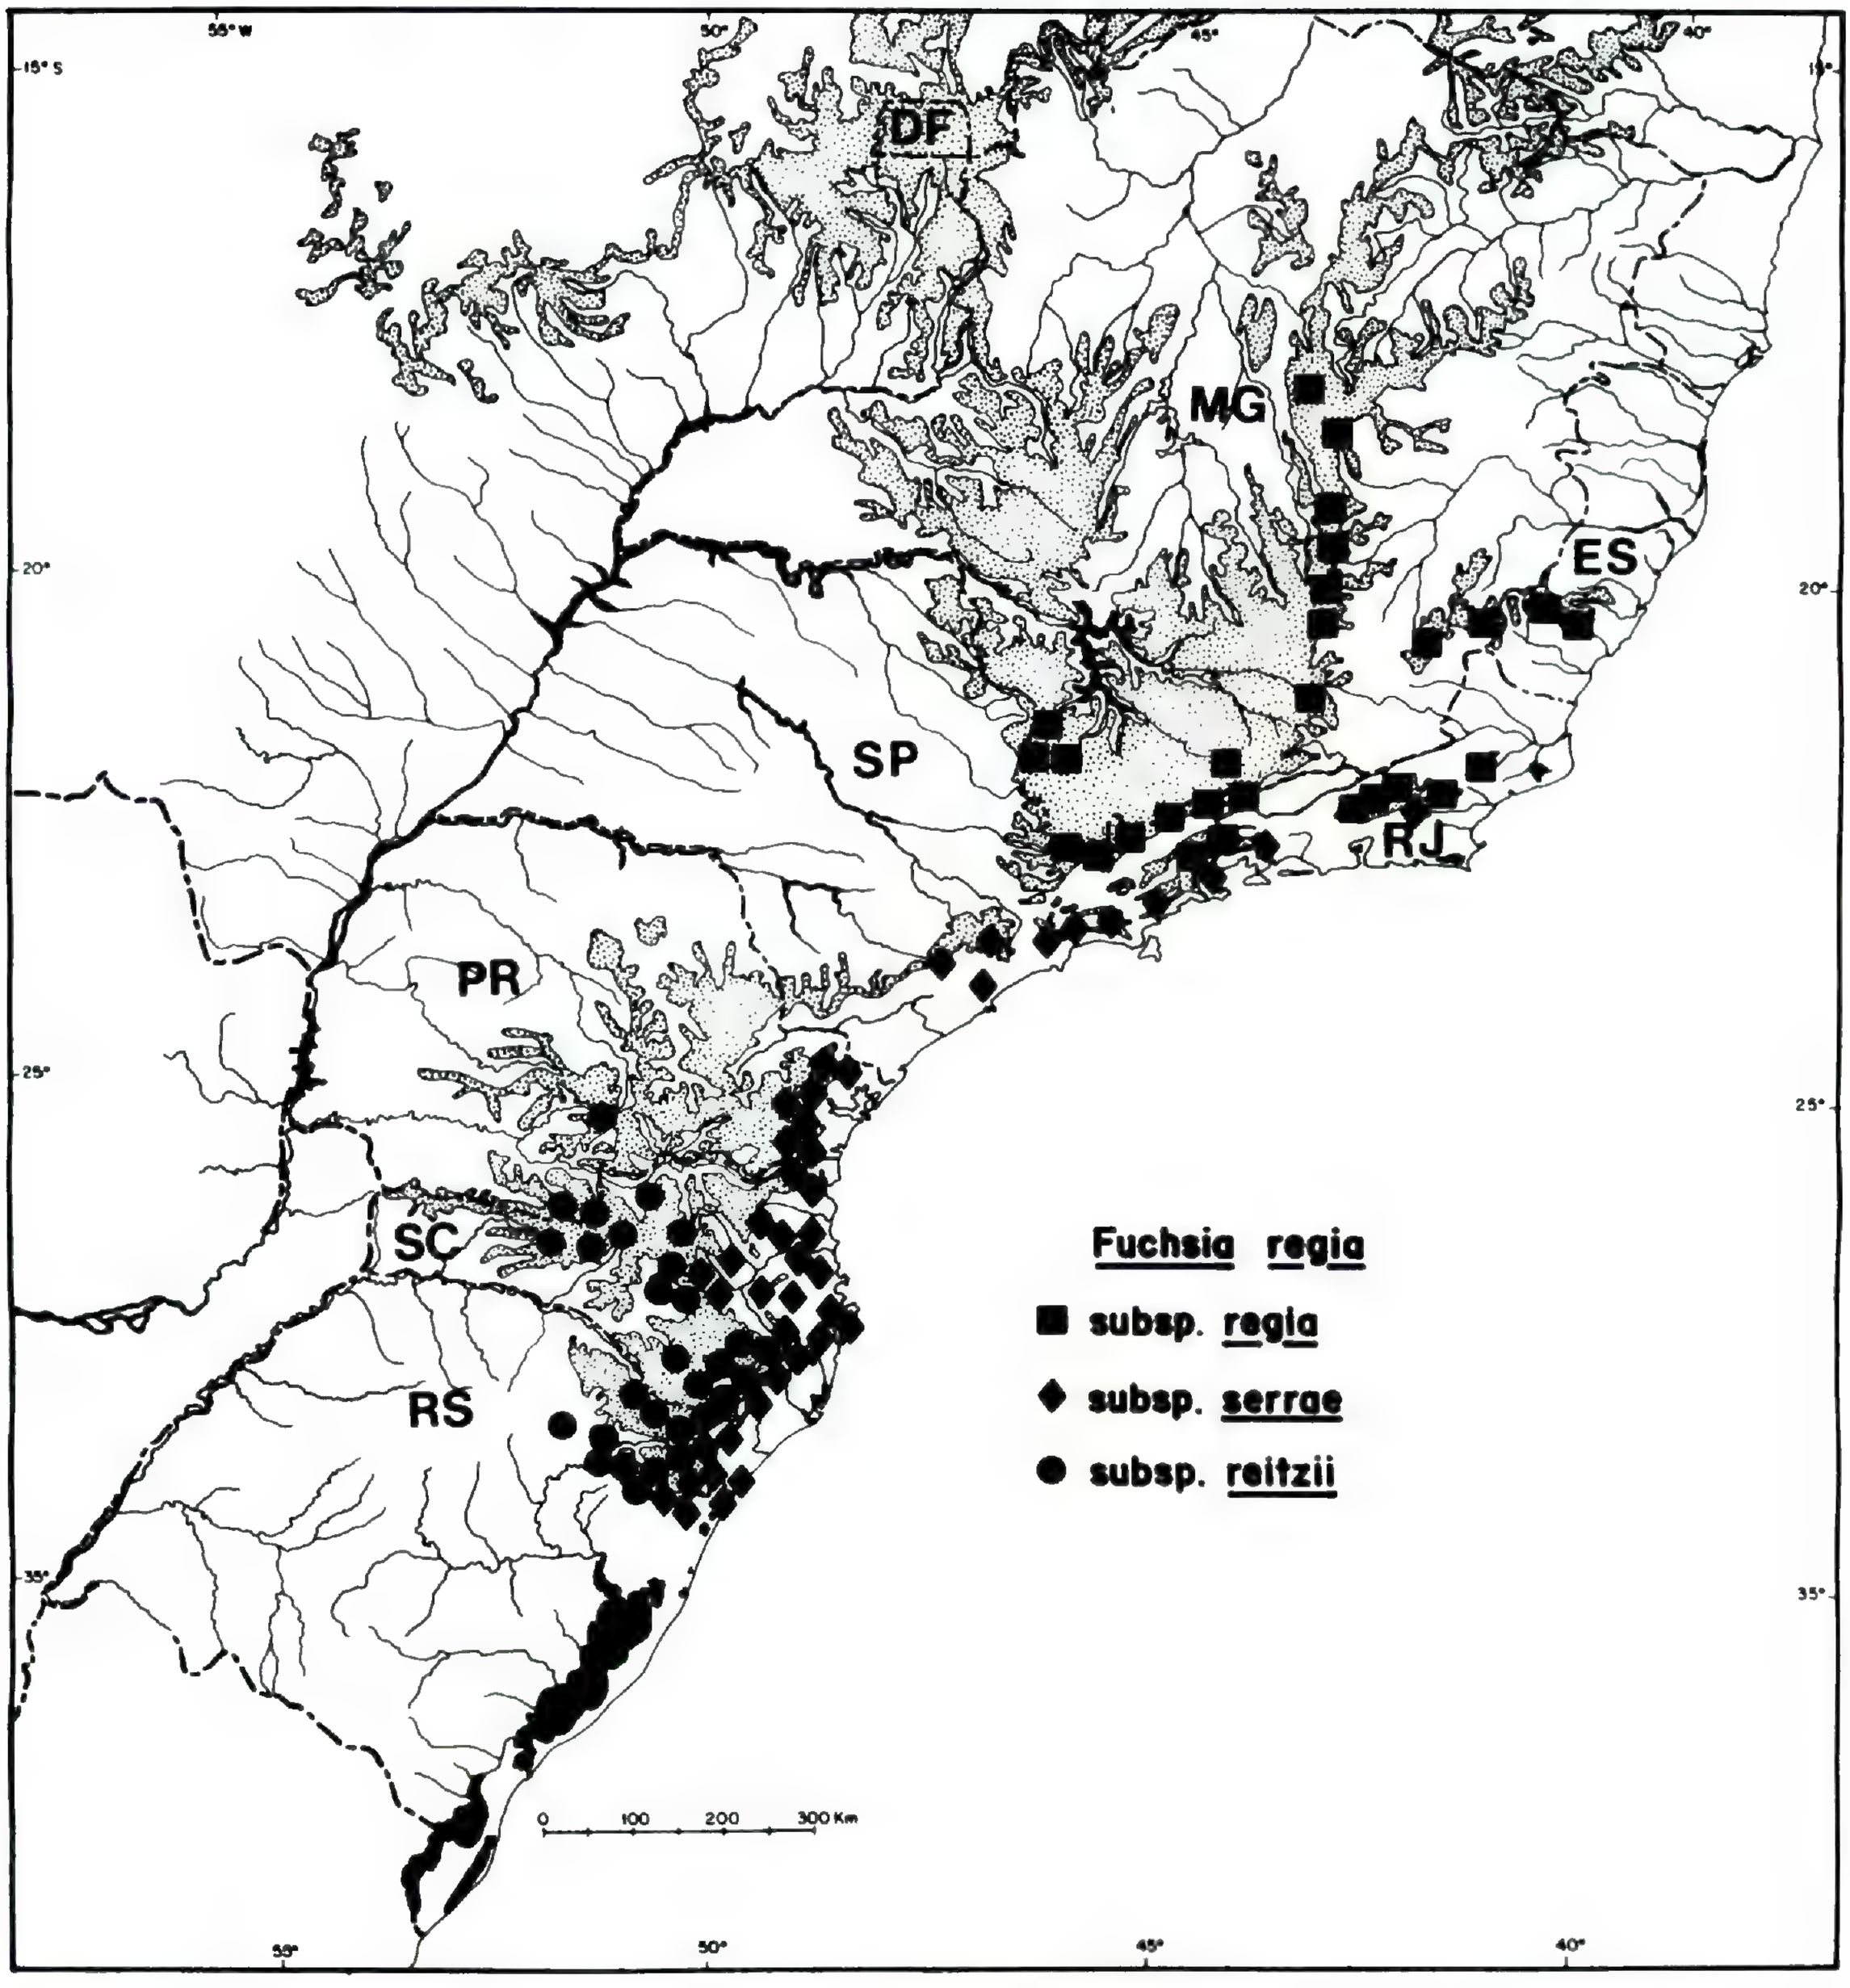

FIGURE 15. Native distributions of the three subspecies of *Fuchsia regia*. Contours higher than 800 m are indicated by the stippled areas. Capital letters are Brazilian state abbreviations. (See caption of Fig. 5.)

surfaces; margin entire to gland-serrate, secondary veins 4–10 per side. Petioles 1–3 mm thick, 3–35 mm long. Stipules triangular, membranous to thick-stubby, 0.8–3 mm long, 0.4–3 mm wide, adjacent ones sometimes fused, usually recurved with age, ephemeral to persistent. Flowers solitary or rarely in pairs in upper leaf axils; pedicels pendulous, 10–55 mm long, usually wine red. Ovary oblong, 5–12 mm long, 2–4 mm wide. Floral tube cylindrical-fusiform, 5–16 mm long, 3–7 mm wide, glabrous to puberulent or pilose outside; nectary smooth or lightly ridged, 2.5–8 mm high. Sepals 15–45 mm long, connate at the base for 3–14 mm; free lobes 3–9 mm wide at base, spreading to recurved or reflexed at anthesis. Tube and sepals red or rose. Petals purple, obovate to spathulate, 10–25 mm long, 8–16 mm wide. Filaments red-purple, 25–45 mm and 20–38 mm long; anthers oblong, purplish, 2–5 mm long, 1–2 mm wide. Style glabrous to pubescent in lower ½; stigma clavate, 2–6 mm long, 1–2 mm wide, exserted 8–25 mm beyond the anthers. Berry oblong, ellipsoid or globose, 10–27 mm long, 9–13 mm thick, dark purple when ripe; seeds tan, oblong to narrowly

triangular, laterally compressed, 1.6–2.5 mm long, 1–1.6 mm wide. Gametic chromosome numbers $n = 22, 44$.

Distribution (Fig. 15). This is the most widely distributed species of *Fuchsia* in Brazil, occurring in the states of Minas Gerais, Espírito Santo, Rio de Janeiro, São Paulo, Paraná, Santa Catarina, and Rio Grande do Sul from 18°20′S to 29°30′S. Most common between 700 and 2,000 m, on the upper, wettest slopes of ranges such as the Serra do Mar, Serra Geral, Serra da Mantiqueira, and Serra do Espinhaço. *Fuchsia regia* subsp. *reitzii* is associated with the *Araucaria* forests of the southern planalto from Paraná to Rio Grande do Sul. Plants occasionally occur as high as 2,400 m on Mt. Itatiaia and at sea level in coastal restingas of Santa Catarina and Rio Grande do Sul. Flowers mainly from October to April.

This is the most variable of the Brazilian species of sect. *Quelusia*. Three distinct and largely allopatric series of populations can be recognized based on differences in several floral and vegetative characters. They intergrade in areas where their ranges overlap, and the presence of octoploid populations in some or all of the populations sampled in each series is unique in the genus. For these reasons, the different series are treated here as subspecies of *F. regia*.

KEY TO THE SUBSPECIES OF *FUCHSIA REGIA*

1a. Sepals strongly connate above the point of insertion of petals and stamens, joined for more than ⅓ of their total length, the free lobes generally recurved; stipules crassate and persistent, giving a nodose appearance to young stems ..... 9b. subsp. *serrae*

1b. Sepals slightly connate at the base, joined for less than ¼ of their total length, the free lobes spreading; stipules membranous or thickened only at the base and young stems not apparently nodose.

2a. Leaves in whorls of 3–5, membranous, tertiary venation conspicuous; margins gland-serrulate and petioles mostly shorter than 10 mm; floral tubes 5–10 mm long, sepals 17–28 mm long ..... 9c. subsp. *reitzii*

2b. Leaves mostly opposite or ternate, subcoriaceous, tertiary venation not conspicuous; margins entire or gland-denticulate and petioles mostly longer than 10 mm; floral tubes 10–16 mm long, sepals 24–45 mm long ..... 9a. subsp. *regia*

9a. Fuchsia regia (Vellozo) Munz subspecies **regia.** *Fuchsia regia* (Vandelli) Munz var. *typica* Munz, Proc. Calif. Acad. Sci. IV. 25: 13. 1943. Vellozo's type illustration shows a plant with narrowly ovate-lanceolate leaves in pairs and threes, and flowers with very shortly connate, long sepals. These characters correspond to the northernmost subspecies, which reaches as far south as the type locality in northern São Paulo state. Figure 16.

Fuchsia integrifolia Cambessèdes in St. Hilaire, Fl. Bras. Merid. 2(17): 273. 1830. TYPE: Brazil. Minas Gerais: "Serra da Caraça, near city of Villa Rica (Ouro Preto) and near São Gabriel," 1819, *Auguste de Saint Hilaire C¹80* (holotype, P, with two different branches, the one to the left the type and tagged as C¹ 80, the one to the right with a tag stating "Serra da Caraça," photograph at F; isotypes, P—again with two different branches, the one to the left numbered C¹ 80, F #1008268 "ex P," RB).

Fuchsia pyrifolia K. Presl, Symbol. Bot. 2: 19, tab. 65. 1834. TYPE: Brazil, "ad Rio Janeiro," *Presl?* (holotype, PRC—445/a).

Shrubs 0.5–5 m tall, occasionally erect but usually scandent, or lianas to 15 m high in trees. Branchlets generally glaucous and wine purple, occasionally loosely to densely pilose, older plants with long hanging branches to 5 m long. Leaves opposite, or in whorls of 3 and 4, subcoriaceous, elliptic to lance-elliptic or ovate, 40–140 mm long, 10–50(–70) mm wide, apex acute to acuminate, base acute to cuneate or rounded, sublustrous green and glabrous to pubescent above, veins often reddish-tinged, paler green and glabrous to pilose below, sometimes with tufts of pilose hairs at the base of the lower midvein; margin subentire to remotely gland-denticulate, secondary veins 6–9(–10) per side. Petioles stout, 2–3 mm thick, canaliculate above, (6–)10–28 mm long, wine purple. Stipules triangular, membranous or thickened at the base, ± recurved, 0.9–2(–3) mm long, 0.5–1.8 mm wide, adjacent ones sometimes fused, the base usually persistent but the tip deciduous. Flowers solitary in upper leaf axils; pedicels 22–55 mm long, pendulous. Ovary cylindrical, 6–11 mm long, 3–4 mm thick. Floral tube narrowly to broadly cylindrical-fusiform, 10–16 mm long, 4–6 mm wide, glabrous to subpilose outside; nectary smooth to ridged, 5–8 mm high. Sepals 24–45 mm long, narrowly lanceolate, connate at the base for 3–7 mm; free lobes 4–9 mm wide at base, spreading at anthesis. Tube and sepals red to rose. Petals violet, obovate, 13–22 mm long, 10–16 mm wide. Filaments red-purple, 25–44 mm and 23–38 mm long; anthers oblong, 3–5 mm long, 1.5–2 mm wide. Style glabrous to pilose in lower half; stigma red, narrowly clavate, 3.5–6 mm long, 1.2–1.6 mm thick, exserted 10–27 mm beyond the anthers when fully extended. Berry oblong-ellipsoid, purple when ripe, 20–25 mm long, 9–12 mm thick; seeds

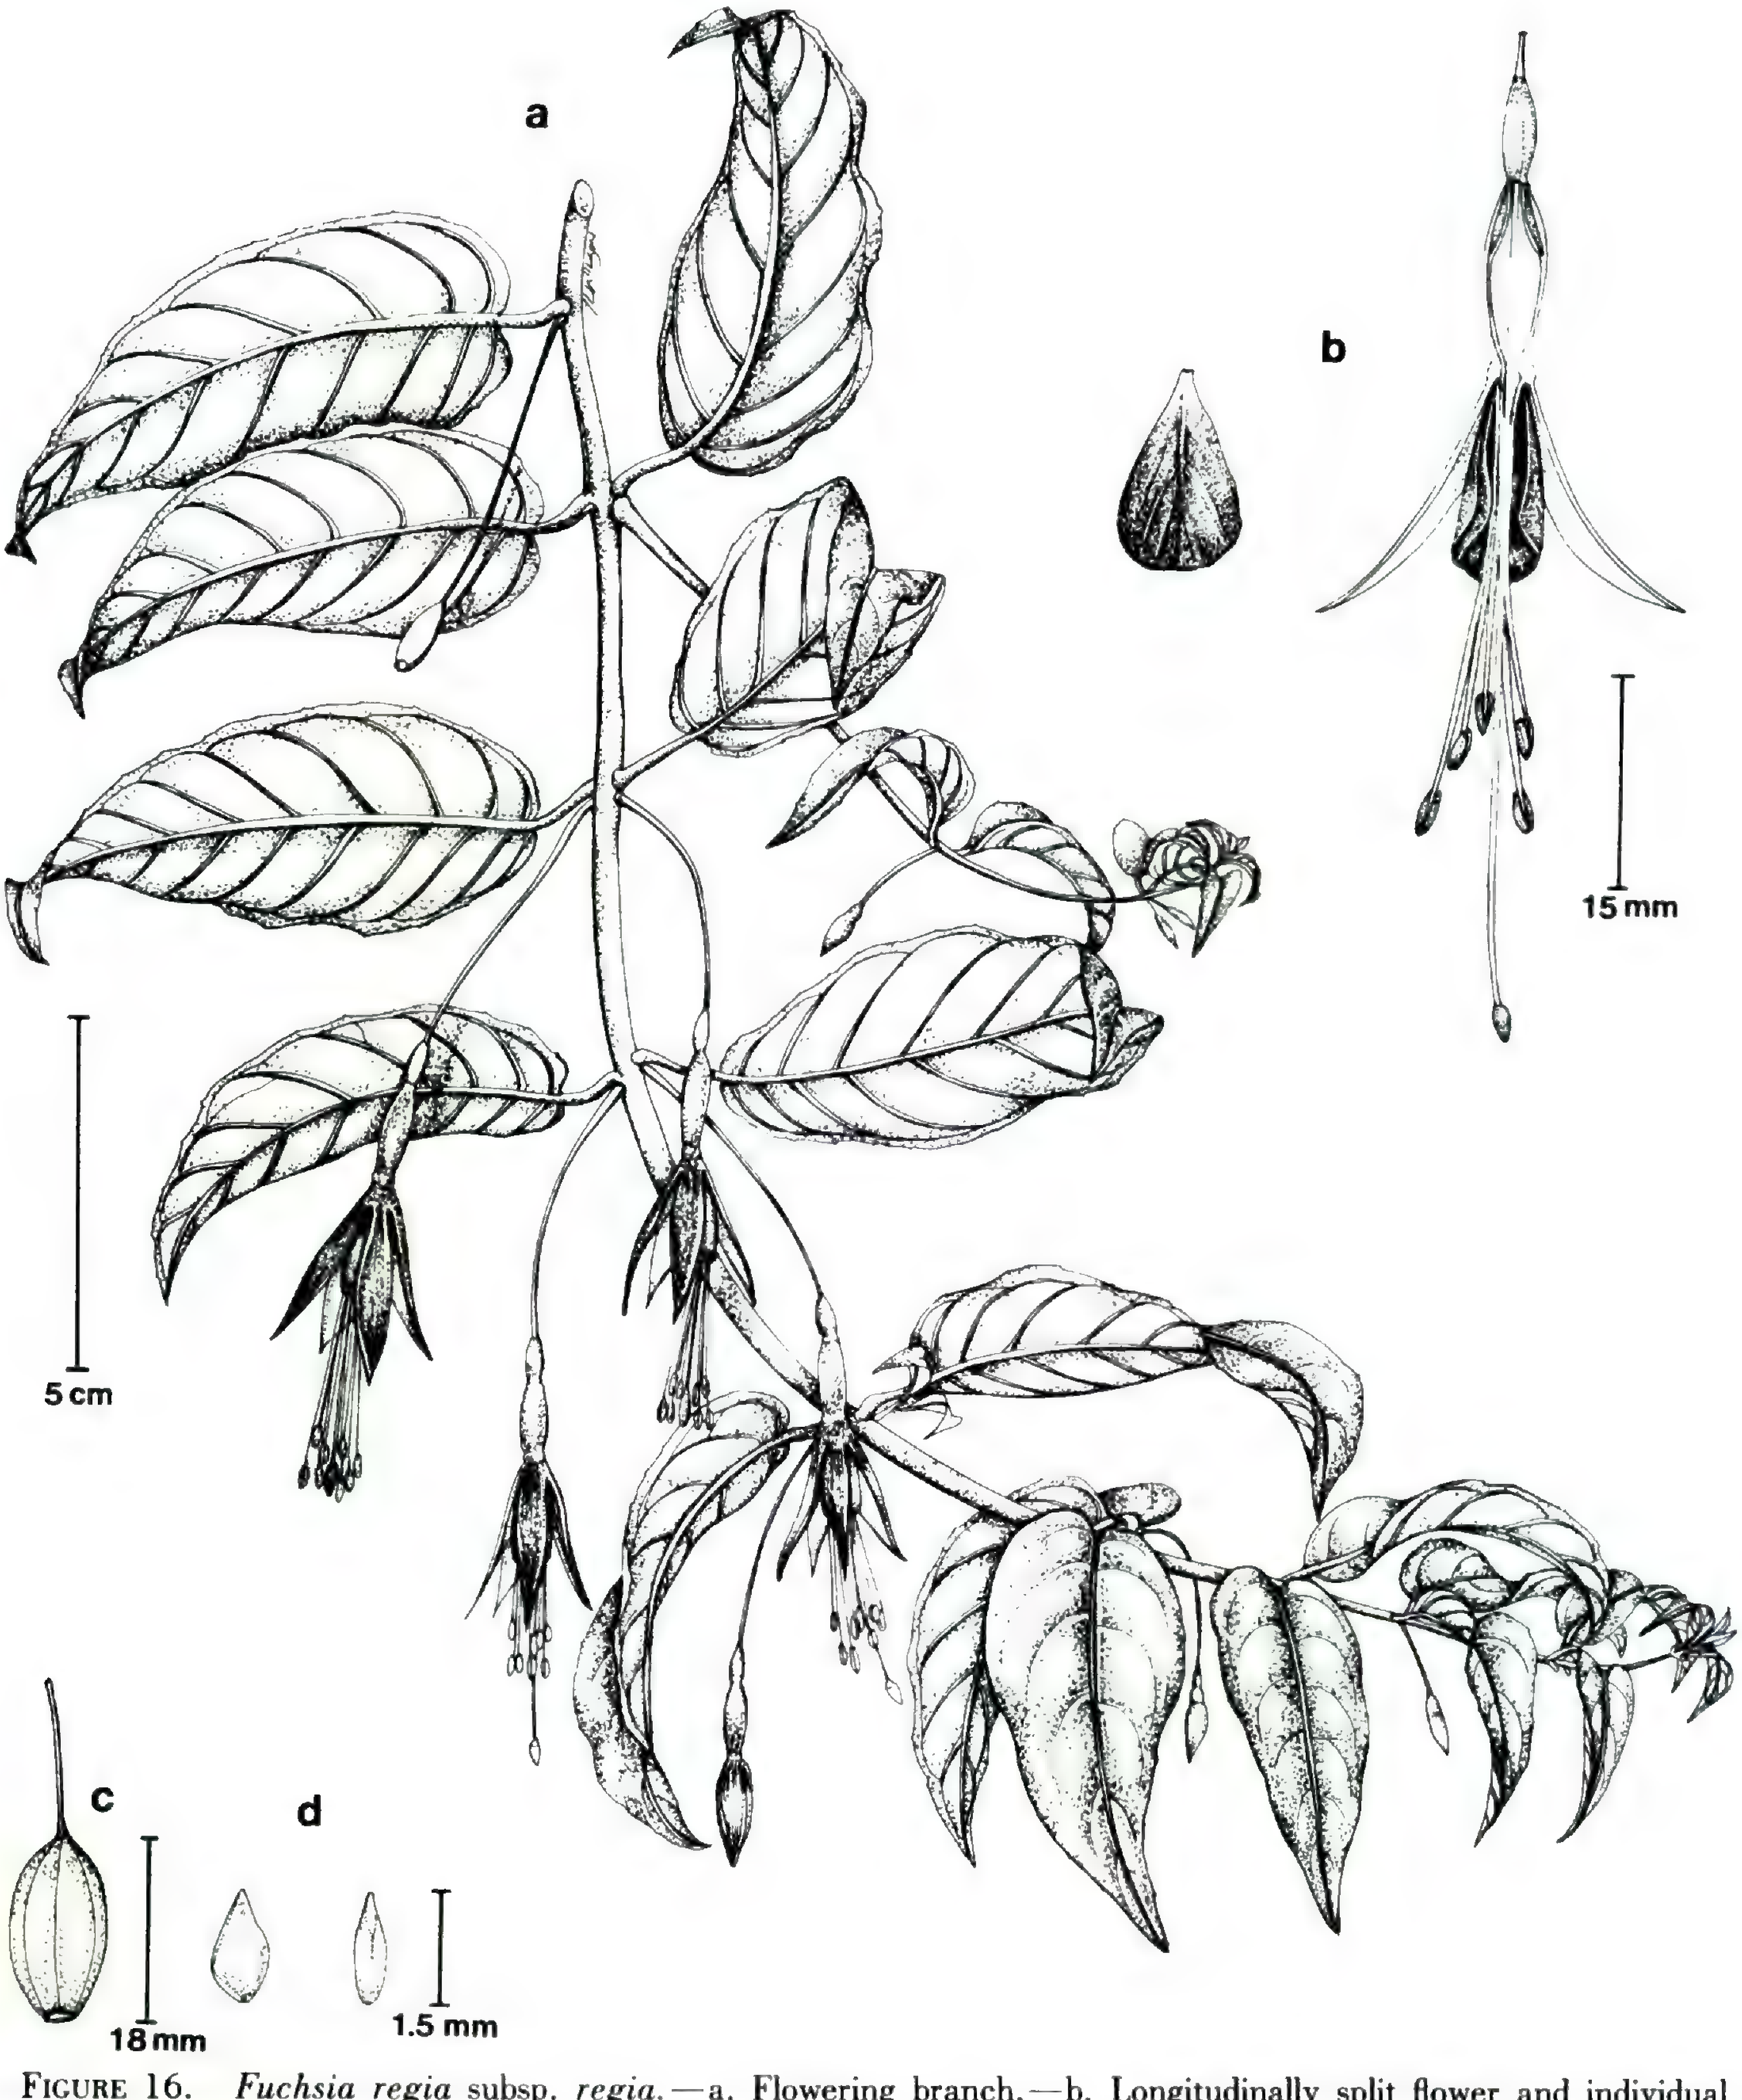

FIGURE 16. *Fuchsia regia* subsp. *regia*.—a. Flowering branch.—b. Longitudinally split flower and individual petal.—c. Slightly immature berry.—d. Seed from (c) in two lateral views. From *Ramamoorthy 683-2*.

1.8–2.8 mm long, 1.2–1.8 mm wide. Gametic chromosome numbers $n = 22, 44$.

Distribution (Fig. 15). In montane cloud forests of the Serra do Mar, Serra do Caparaó, Serra do Espinhaço, Serra da Caraça, Serra da Mantiqueira, Serra da Bocaina, and other subsidiary mountain ranges in Espírito Santo, Minas Gerais, Rio de Janeiro, and northern São Paulo states, 1,000–2,400 m. Flowering mainly from October to April.

Fuchsia regia subsp. *regia* is the most widespread of the Brazilian fuchsias, occurring in four different states, centered in Rio de Janeiro and Minas Gerais. As a result of its fragmented distribution, with populations in a number of discrete mountain ranges, considerable morphological differentiation has taken place throughout the range of this subspecies. It is also cytologically heterogeneous, with tetraploid and octoploid populations. All counts made from Minas Gerais and northern Rio de Janeiro have been tetraploid, whereas octoploid and tetraploid individuals occur together in northern São Paulo and south-central Rio de Janeiro states, in areas such as Itatiaia, Serra da Bocaina, and Serra dos Órgãos (see fig. 9 in Hoshino & Berry, 1989). The different cytotypes cannot be distinguished morphologically, however, and their relationships are not well understood.

Fuchsia regia subsp. *regia* can be distinguished from other taxa of sect. *Quelusia* by having large flowers with spreading sepals and only slight sepal connation, large leaves with petioles generally longer than 10 mm, and mostly glabrous stems and foliage.

This subspecies has a particularly broad ecological tolerance, extending from tall cloud forest at 1,000 m to open campos as high as 2,400 m. When it occurs inside the forest, *F. regia* subsp. *regia* grows as a liana, flowering when its branches reach sufficient light in the tree canopies. As the vegetation decreases in height with greater elevation, it grows as a scandent shrub, and as a short, erect shrub when found on the edges of the open campos. This gradual transition in the habit of subsp. *regia* has been observed in several localities, such as the Serra dos Órgãos and the Morro da Nova Caledônia in Rio de Janeiro, and the Serra do Itacolomi and Serra do Itambé in Minas Gerais.

As a result of its broad altitudinal and geographical distribution, *F. regia* subsp. *regia* occurs sympatrically with four other species from sect. *Quelusia*. In each case, morphologically intermediate individuals have been found that indicate the occurrence of interspecific hybridization (see Appendix). It also occurs sympatrically with *F. regia* subsp. *serrae* in northern São Paulo along the eastern slopes of the Serra da Bocaina, where it forms hybrid populations, with further intergradation southwards along the Serra do Mar as far as Caraguatatuba. These populations are discussed in the Appendix.

Several collections of *F. regia* subsp. *regia* from widely distant localities are unusually pubescent yet do not appear to be the result of hybridization or introgression with pubescent species growing nearby, such as *F. alpestris* or *F. coccinea*. The specimen *Campos Porto 3421* (RB, from Campos do Jordão, São Paulo, 1,600 m) is similar in all morphological features to nearby glabrous populations of *F. regia*, but the entire plant is covered by a dense, pilose indumentum. Three collections from Minas Gerais are similarly pubescent: *Gardner 4555* (K), *Claussen 88* (G), and *Brade 16953* (RB, US, from the Serra do Caparaó). *Martinelli et al. 169* (RB, Vale das Videiras, Petrópolis, Rio de Janeiro) is covered by short, fine pubescence, which is unusual among the populations of *F. regia* from Rio de Janeiro. These pubescent variants are apparently quite rare, and none were found during my fieldwork in Brazil.

9b. Fuchsia regia subsp. **serrae** P. Berry, subsp. nov. TYPE: Brazil. Paraná: Mun. Morretes, Recanto Engº Lacerda, Estrada da Graciosa, 850 m, 28 Jan. 1985, *P. E. Berry, T. Plowman & F. Juarez 4493* (holotype, MO; isotype, MBM; $n = 44$). Figure 17.

Fuchsia affinis Cambessèdes, Fl. Bras. Merid. 2(17): 274. 1830. TYPE: Brazil. Paraná: "in forest near Ferraria, district of Curitiba," May 1820, *Auguste de Saint Hilaire C² 1622* (lectotype, P, here designated; isolectotype, P, with no number). The lectotype sheet contains two different specimens, but the branch corresponding to *St. Hilaire 1622* is clearly marked on the left side; it was annotated, possibly by St. Hilaire, and labeled as the type collection of *F. affinis*.

Fuchsia radicans Miers in Lindley, Bot. Reg. 27: pl. 66. 1841. TYPE: Brazil. Rio de Janeiro: Organ Mts., *John Miers in Feb. 1838* (holotype, BM; isotype, K). There are two sheets of Miers collections labeled as *F. radicans* at BM; one sheet contains three different plants, but the holotype has only one specimen on its sheet, with a pasted blue slip stating

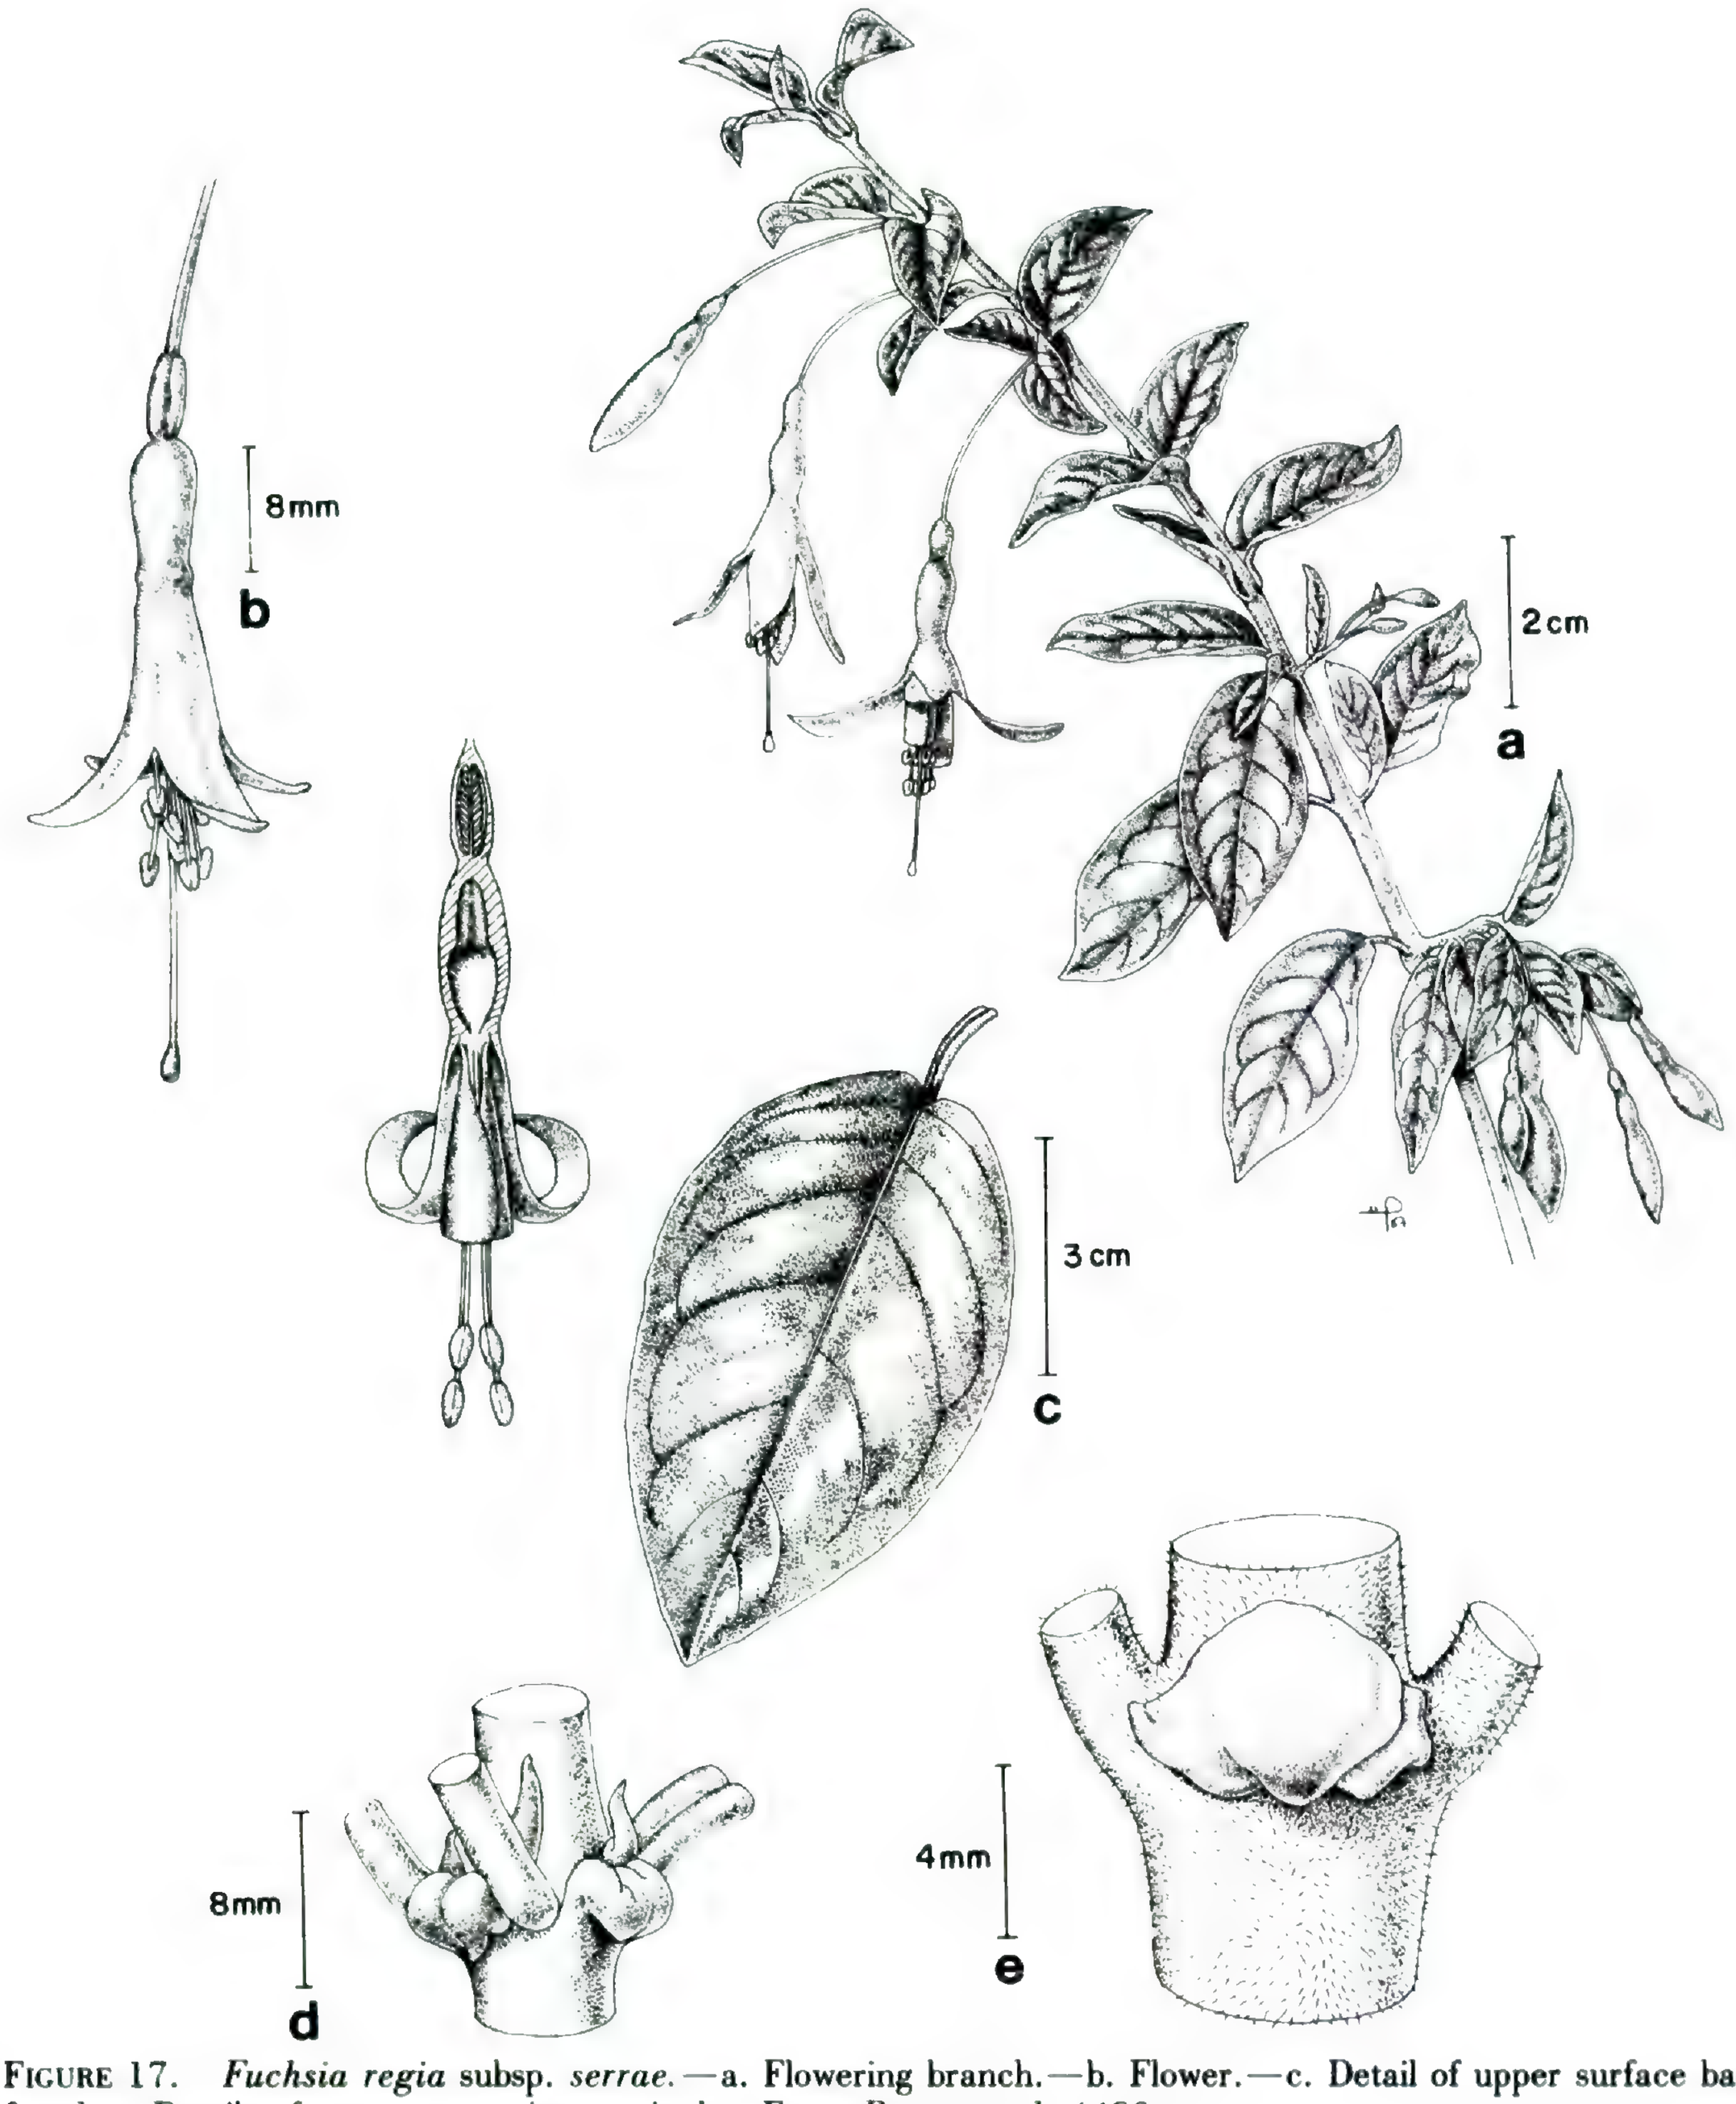

FIGURE 17. *Fuchsia regia* subsp. *serrae*.—a. Flowering branch.—b. Flower.—c. Detail of upper surface basal leaf.—d, e. Details of crassate, persistent stipules. From *Berry et al. 4492*.

"*Fuchsia radicans* Nob., Organ Mts., Feb., 1838" and a small typeset label of "Herb. John Miers."

Frutex 1–4 metralis aliquando in arboribus scandens usque ad 15 m, ramulis plerumque subtiliter puberulentibus interdum dense pilosis, lateralibus saepe brevibus divaricatisque. Folia opposita vel 3–4 verticillata, coriacea, (anguste) ovata ellipticave, margine subintegro, petiolis 1.5–3 mm crassis (7–)10–35 mm longis, stipulis prominentibus incrassatis recurvatis 2–3 mm longis latisque, ca. 0.5 mm crassis, contiguis interdum connatis, facie nodosis. Tubi florales cylindrico-fusiformes (6–)7–15 mm longi, sepalis (15–)19–34 mm longis, (4–)5–7 mm latis, basi (5–)8–14 mm connatis, lobis patentibus saepe recurvatis vel raro reflexis. Bacca oblonga 16–26 mm longa, 9–13 mm crassa, seminibus 2–2.5 mm longis, 1–1.5 mm latis. Numerus gameticus chromosomatum $n = 44$.

Scandent to climbing shrubs 1–4 m tall, or lianas to 15 m high in trees. Branchlets generally finely puberulent, sometimes subglabrous or densely short-pilose, the lateral ones often short and divaricate; older branches on large plants hanging, to 6 m long, with basal stems to 6 cm diam. Leaves op-

posite or in whorls of 3–4, coriaceous, (narrowly) ovate to elliptic, (35–)60–110 mm long, (15–)25–45 mm wide, apex acute to acuminate, base rounded to acute and sometimes ± uneven, smooth and lustrous dark green above, pale below, glabrous to lightly pubescent on both surfaces; margin subentire, secondary veins 5–8(–10) per side. Petioles 1.5–3 mm thick, usually dull purple, canaliculate above, (7–)10–24(–35) mm long. Stipules prominent, crassate, 2–3 mm wide, 2–3 mm long, ca. 0.5 mm thick, recurved, persistent, adjacent ones sometimes fused, drying tan-colored and giving a nodose appearance to the stems. Flowers solitary in upper leaf axils; pedicels 20–45 mm long, pendulous. Ovary cylindrical, 6–12 mm long, 2–4 mm wide. Floral tube cylindrical-fusiform, (6–)7–15 mm long, 3–7 mm wide, glabrous to puberulent outside; nectary ± smooth, 5–8 mm high. Sepals (15–)19–34 mm long, connate at the base for (5–)8–10(–14) mm and forming a long, usually 4-ridged sepal tube, the free lobes (4–)5–7 mm wide at base and spreading to most often recurved or rarely reflexed at anthesis. Tube and petals bright red. Petals violet, obovate to spathulate, 11–20 mm long, 8–15 mm wide. Filaments red, 22–48 and 20–40 mm long; anthers red-purple, 3–4 mm long, 1.5–2 mm wide. Style red, glabrous to pilose near base; stigma red, clavate, 2–4 mm long, 1–2 mm wide, exserted 15–23 mm beyond the anthers. Berry oblong, 16–26 mm long, 9–13 mm thick, purple when ripe; seeds 2–2.5 mm long, 1–1.5 mm wide. Gametic chromosome number $n = 44$.

Distribution (Fig. 15). Typical of dense cloud forests on the crest and wet, coastal escarpments of the Serra do Mar and Serra Geral, in Rio Grande do Sul, Santa Catarina, Paraná, São Paulo and southern Rio de Janeiro states, from 500 to 1,450 m. Also found at lower elevations on the top of isolated "morros" in the Atlantic coastal forest of Santa Catarina, or rarely occurring near sea level in coastal restingas in northern Rio Grande do Sul and southern Santa Catarina. Flowering mainly from November to March, occasionally in other months.

Fuchsia regia subsp. *serrae* is the only taxon in sect. *Quelusia* besides *F. brevilobis* with the sepals connate for over one-third of their length. It is unique in its persistent, crassate stipules and lustrous, subcoriaceous leaves with thick petioles. Unlike the other subspecies of *F. regia*, the sepals are usually recurved at anthesis and four-angled in bud.

This subspecies is most common along the crest and upper slopes of the "serras," the steep and very wet region on the eastern edge of the southern Brazilian planalto as it drops abruptly to the Atlantic coastal plains. The rugged terrain, with sheer drops of 800 m or more, such as those found in the Aparados da Serra in northern Rio Grande do Sul, creates a broad diversity of microhabitats reflected in the large degree of variability in different populations of this subspecies. For example, low, densely branched subshrubs characteristically grow in rock crevices on the steep drop-offs of the Aparados, while tall lianas with long, drooping branches are found in more protected, forested areas near the crest of the Serra.

The degree of sepal connation varies considerably in different parts of the range of *F. regia* subsp. *serrae*. In northern Paraná, where it occurs together with the long-tubed *F. brevilobis*, the sepals are often joined for half or more of their length. Along the Serra Geral in southern Santa Catarina and Rio Grande do Sul, however, the sepals are less joined than populations further north; in extreme cases, individuals like *Falkenberg 3744* and *3745* have the sepals joined for only 4–6 mm, but their thick, shiny leaves and nodose stipules are characteristic of subsp. *serrae*.

Along the edge and just inland from the steep drop-offs of the Serra Geral in Rio Grande do Sul

and southern Santa Catarina, a sharp ecotone occurs between the drier, flatter planalto and the wet, steep coastal slopes. In this area, *Fuchsia regia* subsp. *serrae* occurs sympatrically with the easternmost populations of *Fuchsia regia* subsp. *reitzii*, and the two subspecies intergrade extensively in areas such as Itaimbezinho, Serra da Rocinha, and the edge of the Serra Geral near Uribici and Bom Jardim da Serra in Santa Catarina. Further discussion and a list of intermediate, probable hybrid individuals between these two subspecies is found in the Appendix.

Towards the northern limits of the range of *Fuchsia regia* subsp. *serrae*, this subspecies also contacts populations of *Fuchsia regia* subsp. *regia*, especially in the Serra da Bocaina in northern São Paulo state. Populations of subsp. *serrae* predominate there on the lower, coastal slopes below 1,100 m, while subsp. *regia* occurs at higher elevations and further inland. Extensive intergradation between these two subspecies occurs on the upper coastal slopes of the Serra, where unusually pilose individuals are also found. Some of these individuals are octoploid, as in all the southern populations of subsp. *serrae*, while others are tetraploid, like some of the populations of subsp. *regia* from the Bocaina range and further north (Hoshino & Berry, 1989). Although *F. regia* subsp. *regia* reaches its southern limit at the Serra da Bocaina, populations of *Fuchsia* with mixed ploidy levels and dense pubescence occur south of the Bocaina area as far as Ubatuba in the Serra do Mar of north-central São Paulo state (Hoshino & Berry, 1989).

Fuchsia regia subsp. *serrae* also occurs sympatrically with *F. brevilobis* in several localities in Paraná. Although *F. regia* is octoploid in this area, and *F. brevilobis* is tetraploid, the occurrence of morphologically intermediate individuals indicates that hybridization has taken place between these taxa (see Appendix). The unusually long sepal tubes of populations of *F. regia* subsp. *serrae* in this area are characteristic of *F. brevilobis* and may be the result of introgression with this species.

Outside of its typical montane habitats, *F. regia* subsp. *serrae* has also been found in coastal restingas at sea level, near the Rio Grande do Sul–Santa Catarina border. Reitz (1961) first detected this apparent anomaly in the distribution of typically montane taxa, and found it to occur in at least ten other species that normally occur along the crest of the Serra Geral. The presence of these species in the restingas must represent recent chance introductions from the nearby serras, as the coastal plains of this area are only of Quaternary age (Klein, 1984).

9c. Fuchsia regia subsp. **reitzii** P. Berry, subsp. nov. TYPE: Brazil. Santa Catarina: Município São Joaquim, Fazenda de Laranja, São Joaquim, 1,400 m, 13 Jan. 1959, *P. Raulino Reitz & Roberto Klein 8135* (holotype, UC #240288; isotypes, B, BR, G, GH, HBR, ICN, K, NY, U). Figure 18.

Fuchsia pubescens Cambessèdes in St. Hilaire, Fl. Brasil. Merid. 2(17): 275, tab. 134. 1830. TYPE: Brazil: "in fields near the Rio Yapó in the part of São Paulo Province called Campos Geraes," currently in Paraná, Municípios Piraí do Sul and Jaguariaíva, May 1820, *Auguste de Saint Hilaire C² 1545* (holotype, P, on the same sheet with a small piece of *St. Hilaire 2276*, which is *F. coccinea* from Minas Gerais; isotypes, P, as *St. Hilaire C¹ 1545* and also mixed with *2276*, MPU). The holotype at P was annotated as the type specimen of *F. pubescens*, and Cambessèdes's illustration shows the verticillate leaves and flower and round fruits characteristic of *F. regia* subsp. *reitzii*. The other collection from Minas Gerais cited by Cambessèdes in his protologue is *F. coccinea*.

Frutex erectus scandensve 1–4 metralis, ramulis purpurascentibus subglabris vel dense puberulentibus vel pilosis ferruginescentibus, ramis cito excorticatis. Folia 3–4(–5) verticillata, elliptica ad anguste ovato-elliptica, apice acuta basi acuto-acuminata obtusave, nervis tertiariis conspicuis, margine glanduloso-serrulato, petiolis 3–7(–15) mm longis, stipulis lanceolatis membranaceis 0.8–1.4 mm longis. Flores verticillati, tubis floralibus cylindrico-fusiformibus 5–11 mm longis, sepalis anguste lanceolato-oblongis 17–28 mm longis, basi 2–6 mm connatis sub anthesi patentibus, petalis obovatis 10–15(–20) mm longis, 7–13 mm latis. Bacca globosa vel interdum ellipsoidea 10–16 mm longa, 9–12 mm lata, seminibus 1.6–2 mm longis, 1–1.3 mm latis. Numerus gameticus chromosomatum $n = 44$.

Erect to scandent shrubs 1–3 m high, or climbers in trees or brush to 4 m tall. Young branches purplish, subglabrous to densely puberulent or pilose, the pubescence ferrugineous in some plants; older stems with reddish to pale tan, readily exfoliating bark. Leaves in whorls of 3 or 4(–5), firmly membranous, (narrowly) elliptic to narrowly ovate-elliptic, 20–65(–90) mm long, 7–20(–40) mm wide, acute at the apex, acute to attenuate or obtuse at the base, dark dull green and subglabrous above, pale green and subglabrous to densely pubescent below with conspicuous tertiary venation, margin serrulate, usually with prominent glandular teeth ascending apically at a ± 45° angle, secondary veins 5–8 per side. Petioles 3–7(–15) mm long. Stipules lanceolate, 0.8–1.4 mm long, 0.4–1 mm wide, thick at the base, purple, drying dark, divergent to recurved with age, with apiculate, semipersistent tips. Flowers solitary or sometimes 2 per leaf axil, near branch tips; pedicels slender, 10–

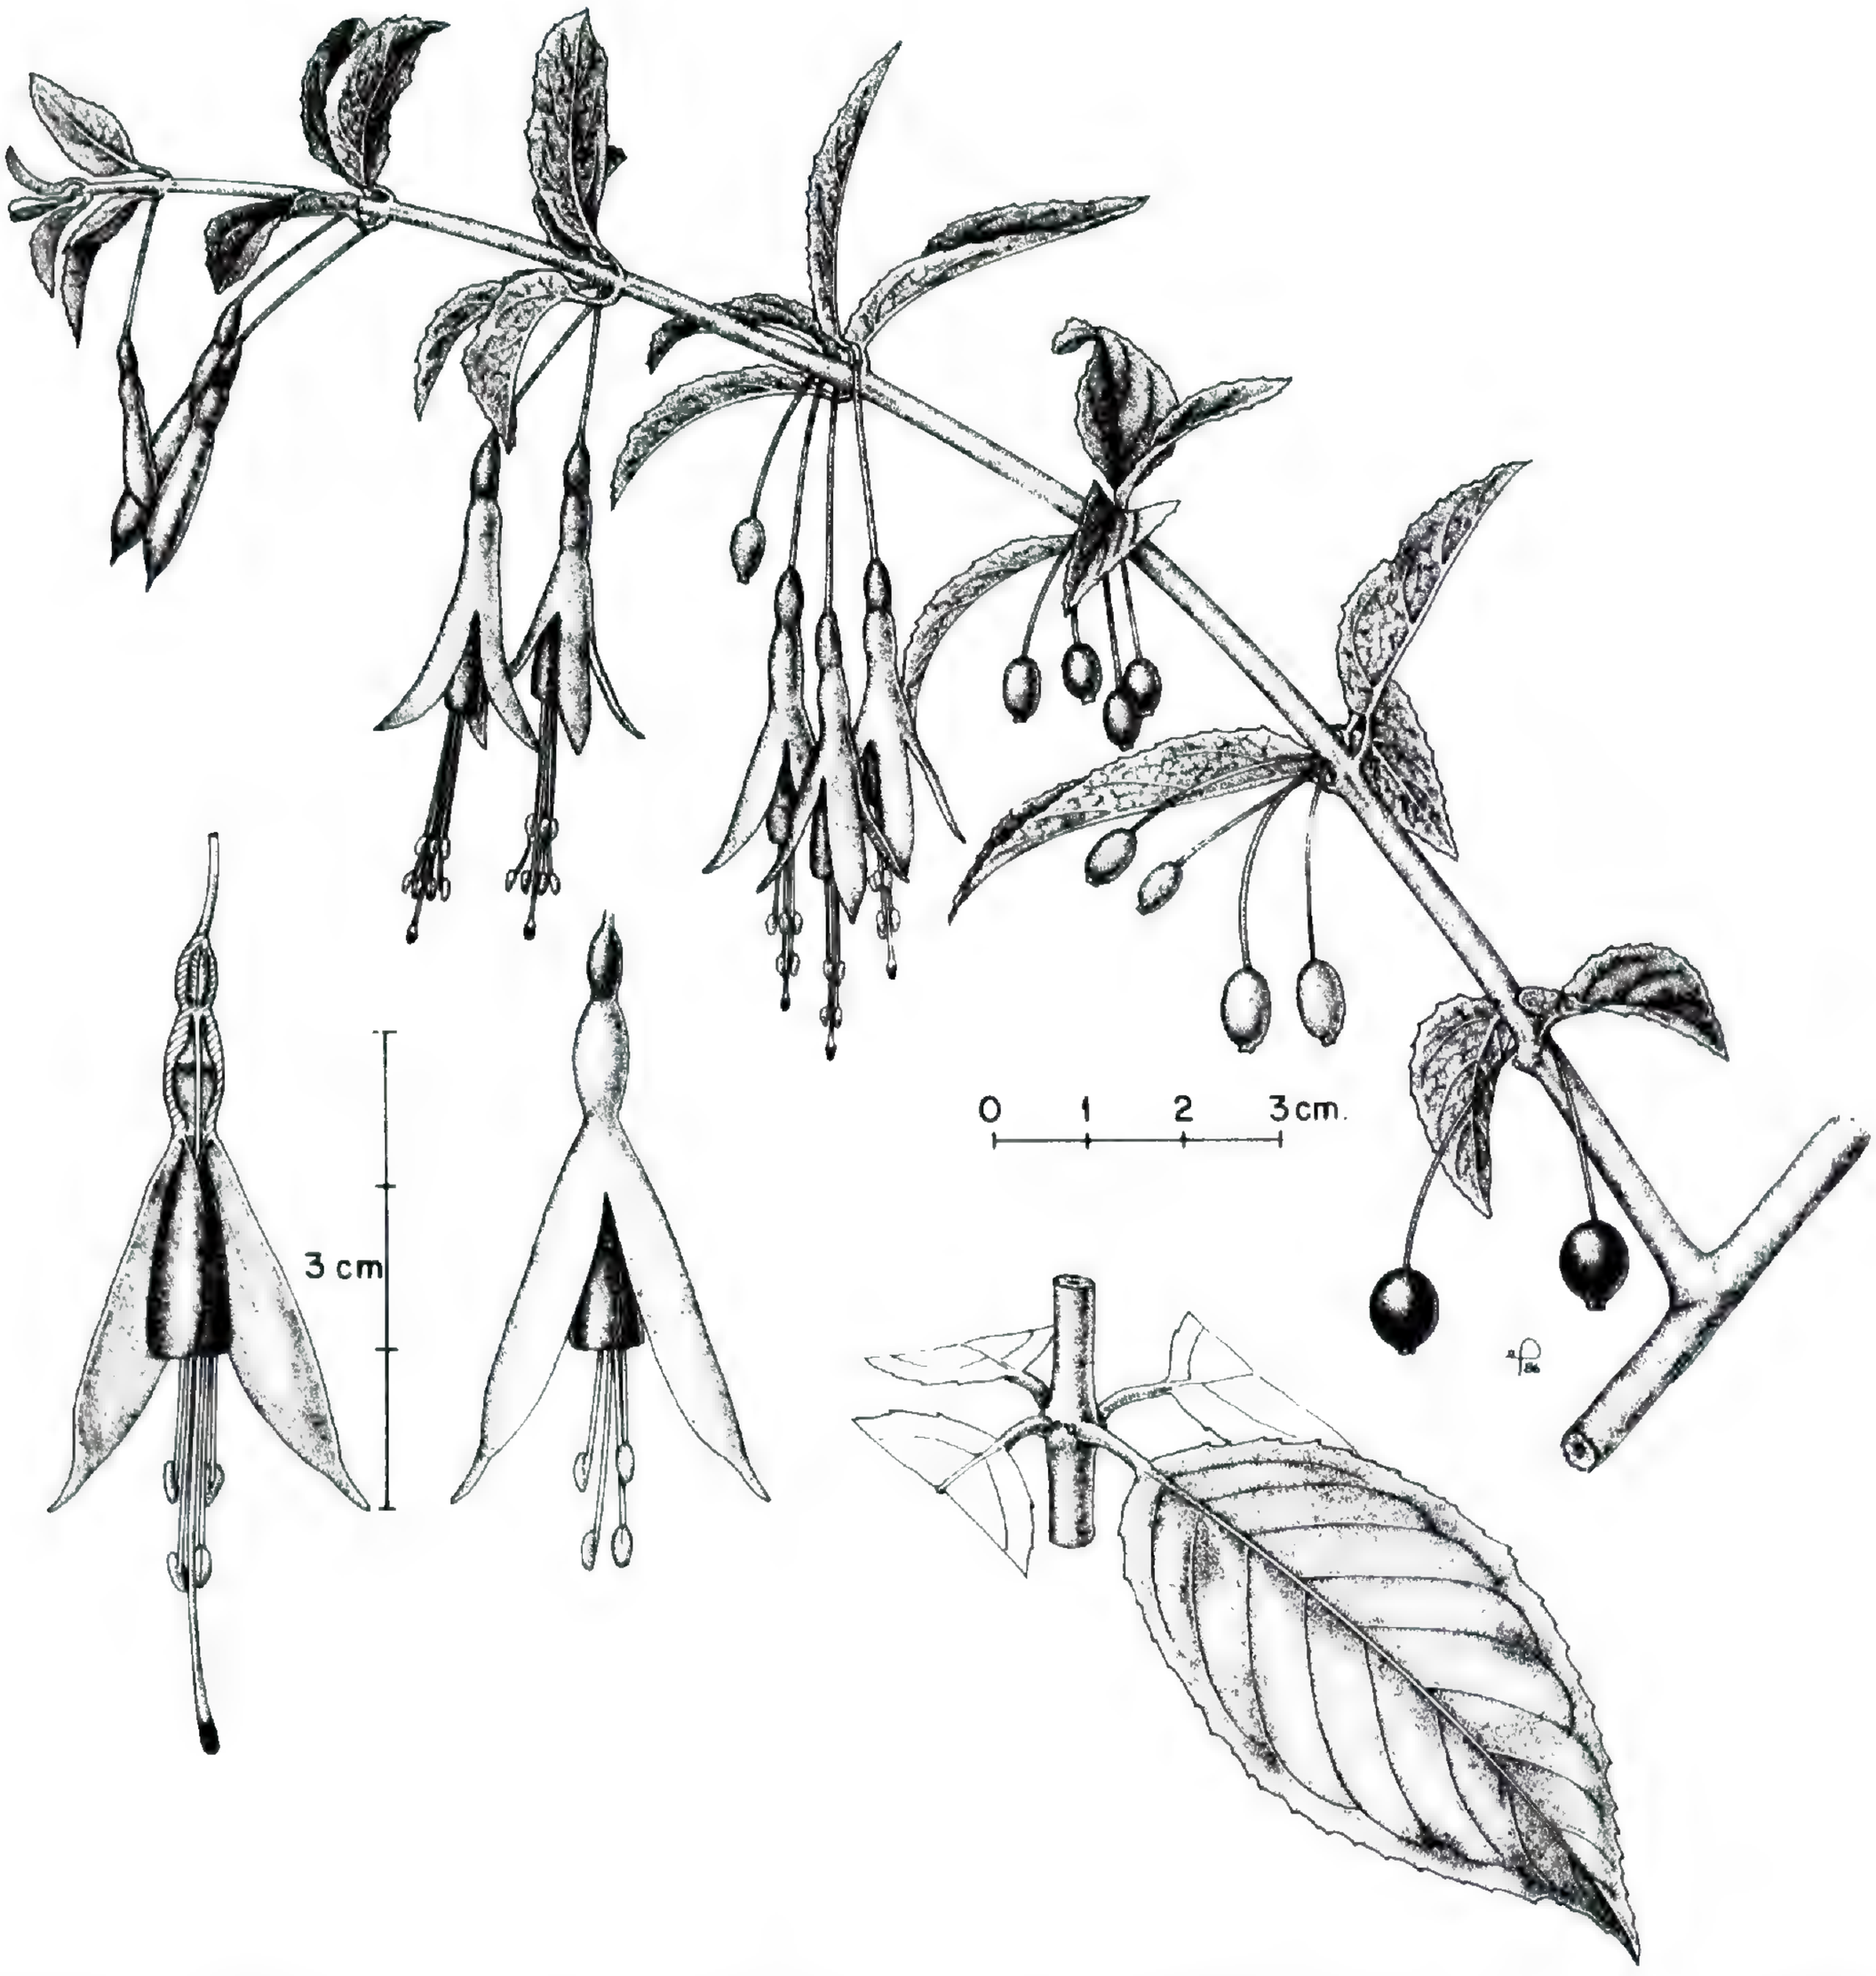

FIGURE 18. *Fuchsia regia* subsp. *reitzii*. Flowering branch, detail of flowers, and detail upper surface of basal leaf. From *Berry et al. 4512*.

35(–50) mm long, pendulous. Ovary oblong, (4–)5–9 mm long, 2–4 mm wide. Floral tube cylindrical-fusiform, 5–9(–11) mm long, 2–4(–6) mm wide, subglabrous to puberulent or loosely pilose outside, glabrous inside; nectary smooth, 2.5–5 mm high. Sepals 17–28 mm long, narrowly lance-oblong, connate at the base for 2–6 mm; free lobes 3–5(–6) mm wide at base, subacuminate at the apex, spreading at anthesis. Tube and sepals red. Petals purple, obovate, 10–15(–20) mm long, 7–13 mm wide. Filaments reddish, 25–45 mm and 20–38 mm long; anthers red-purple, oblong-elliptic, 2–2.5 mm long, 1–1.5 mm wide. Style glabrous to pilose in lower half; stigma clavate, 2–2.5 mm long, 1–1.5 mm wide, exserted 5–15 mm beyond the anthers. Berry globose to ellipsoid, shiny dark purple when ripe, (10–)12–16 mm long, 9–12 mm wide; seeds tan, 1.6–2 mm long, 1–1.3 mm wide. Gametic chromosome number $n = 44$.

Distribution (Fig. 15). Occurring principally in low wooded areas and usually along streams or seepages, on the planalto west of the Serra Geral and Serra do Mar in south-central Paraná, Santa Catarina, and Rio Grande do Sul, at 880–1,730 m. At the top of the escarpments of the coastal mountain ranges subsp. *reitzii* intergrades with *F. regia* subsp. *serrae*. Flowers mainly from November to March.

Fuchsia regia subsp. *reitzii* is distinguished by its whorled, membranous leaves with gland-serrate margins and a matte surface having more noticeable tertiary venation than the other subspecies of *F. regia*. Compared with *F. regia* subsp. *serrae*, the only other *Fuchsia* that grows near populations of subsp. *reitzii*, the sepals are much less joined and spreading (instead of recurved), the stipules are much less prominent, the leaf bases are more acute, and the berries are rounder. This subspecies is named in honor of P. Raulino Reitz of the Herbário Barbosa Rodrigues, Itajaí, Santa Catarina, who has made great contributions to the knowledge of the flora of Santa Catarina.

Subspecies *reitzii* is restricted to the planalto west of the coastal mountain ranges of southernmost Brazil. Its overall distribution in this area parallels that of *Araucaria angustifolia*, although it does not tolerate the shade of the dense conifer forests. Both species extend as far east as the edge of the coastal escarpments but end abruptly there

and do not appear on the seaward slopes or in the lower, coastal forest (Hueck, 1953).

Along the eastern edge of the planalto, where sharp drop-offs usually occur down to the Atlantic lowlands, the range of *F. regia* subsp. *reitzii* overlaps with *F. regia* subsp. *serrae*, which extends up from the moist, coastal slopes of the serras. A great deal of intergradation and variation exists in the *Fuchsia* populations of these areas, especially at the crest itself and just inland of the steep drop-offs. In some instances, the extreme local variability is indicative of hybrid swarms, while in other sites, odd variants are found that can extend beyond the normal limits of variation of either subspecies (see Appendix).

A number of unusually pubescent individuals, usually with conspicuously tan or ferrugineous hairs, occur in populations near the southern and western extremes of the range of subsp. *reitzii* in Rio Grande do Sul. Collections from the Farroupilha area, such as *Rambo 45781*, *45782*, and *40172* and *Camargo 980*, are uniformly pubescent, while others, such as *Rambo 31024* from Vila Oliva near Caxias, and *Rambo 51576* from Passo do Socorro near Vacaria, occur together with more typical subglabrous individuals of the subspecies.

APPENDIX. Natural hybrids in *Fuchsia* sect. *Quelusia*

The main criterion used in detecting hybrids was the morphological intermediacy of several characters. In all cases, the putative parents were known to occur nearby.

1. *F. magellanica* × *F. lycioides*

F. macrostemma var. *parviflora* W. J. Hooker, Bot. Misc. 3: 309. TYPE: Chile. Valparaíso, 1832, *Bridges 199* (holotype, K—Benth.; isotype, CGE).

Specimens examined. CHILE. V REGION (VALPARAÍSO): Valparaíso, *Bertero 1006* (G, GH); in valleys near Valparaíso, *Bridges s.n.* (CGE, K—Hook.).

Representative cultivated specimens. CHILE: Juan

Fernández Islands, Más Atierra, *Meyer 9551* (MO). U.S.A. California: Berkeley, *Bracelin 1422* (BM). ZIMBABWE. Salisbury, *Biegel 5549* (K).

Fuchsia lycioides belongs to a different section, *Kierschlegeria*, and differs widely from *F. magellanica* in its small, alternate leaves, spinose leaf bases, smaller flowers with included stamens and reflexed sepals, and generally occurs in much drier habitats. Both species are tetraploid (Hoshino & Berry, 1989) and have been shown to be closely related by chloroplast DNA restriction site analysis (Sytsma & Smith, 1988). The ranges of the two species barely overlap in the hills around Valparaíso, where several natural hybrids were collected in the early 1800s. These plants are characterized by small flowers with larger, convolute petals than those of *F. lycioides*. The leaves are larger and more often opposite than in *F. lycioides*, with the characteristic dentation of *F. magellanica*. They also lack the spinose leaf bases typical of *F. lycioides*. The natural habitats where the early hybrids were collected have probably been totally eliminated by urban growth.

Hybrids of these two species appear quite often in cultivation and have sometimes been confused with the true *F. lycioides*, as in the cytological study of Chaudhuri (1956).

2. *F. regia* subsp. *regia* × *F. alpestris*

Specimens examined. BRAZIL. RIO DE JANEIRO: Pedra Dubois, Santa Maria Madalena, *Santos Lima & Brade 14240* (B, RB); *Plowman & de Lima 12885* (F, MO).

Both parental species occur locally on Pedra Dubois; the specimens cited above are intermediate in their short, fine pubescence, petiole length (6–10 mm), and flower size (floral tubes 10–12 mm long).

3. *F. regia* subsp. *serrae* × *F. brevilobis*

Specimens examined. BRAZIL. SÃO PAULO: Reserva Carlos Botelho, between Sete Barras and São Miguel Arcangel, 800 m, *Prance et al. 6896* (MBM). PARANÁ: 13 km W of Sesmaria and Rio Capivari, Mun. Bocaiúva do Sul, 815 m, *Berry et al. 4448* (MBM, MO; $n = 44$); road from Eng°. Lange train station and Prainhas, 310 m, *Cordeiro et al. in 16 Jan. 1987* (MBM; $n = 22$).

Fuchsia brevilobis is sympatric with *F. regia* subsp. *serrae* over most of its range but usually grows at lower elevations. These taxa are unique in the section in having their sepals connate for more than one-third of their length, but *F. brevilobis* has more membranous leaves that are narrower, shorter-petioled, and more pubescent than *F. regia* subsp. *serrae*, while the latter has more prominent, persistent stipules. The flowers of *F. regia* subsp. *serrae* also differ from *F. brevilobis* in their four-ridged buds, glabrous, nitid surface, and flaring sepal tube. The intermediate individuals cited above are from three different localities where the parent species are locally present. In the Capivari locality, the same hummingbird was observed visiting flowers of both species in succession.

Further experimental work on artificial hybrids of these two taxa is desirable, since only tetraploid counts have been obtained from *F. brevilobis*, and all individuals examined of *F. regia* subsp. *serrae* have been octoploid (Hoshino & Berry, 1989). The count obtained from *Cordeiro et al. in 16 Jan 1987* was tetraploid, indicating that it may only be a variant of *F. brevilobis*, and that of *Berry et al. 4448* was octoploid, as found in *F. regia* subsp. *serrae*.

4. *F. regia* subsp. *regia* × *F. campos-portoi*

Specimens examined. BRAZIL. RIO DE JANEIRO: Itatiaia, just above Hotel Brocken-Holsene, road to Abrigo Rebouças, 2,340 m, *Berry et al. 4440* (MO, RB; $n = 22$); Itatiaia, Agulhas Negras, *Lanstyak 253* (RB #61360).

Fuchsia campos-portoi is endemic to the high-altitude campos of Mount Itatiaia and is very distinctive in its small, narrow, strongly serrate leaves and small, short-tubed flowers. *Fuchsia regia* is common in forests at lower elevations on the same mountain range and occurs together with *F. campos-portoi* in thickets near the treeline above 2,200 m. Both specimens cited above are intermediate in leaf size, number of secondary veins, and floral features, such as the ratio of tube to sepal lengths. Meiosis in buds of *Berry et al. 4440* was normal, with the same chromosome number as recorded in local parental populations.

5. *F. regia* subsp. *regia* × *F. coccinea*

Specimens examined. BRAZIL. MINAS GERAIS: Serra do Itacolomi, near base of Pico do Itacolomi, 1,500–1,700 m, *Badini 22451* (OUPR); *Berry et al. 4546* ($n = 22$), *4547*, *4548* (MO, RB); *Falkenberg 3380* (FLOR); *Mello Barreto 9168* (R); Serra da Caraça, *Mello Barreto 7157* (BHMH).

Fuchsia coccinea typically grows in thickets amid the rocky, open campo of the highest peaks in Minas Gerais. On the Serra do Itacolomi, fire has destroyed much of the woody vegetation on the highest slopes; *F. coccinea* is now very rare in that area, and intermediate forms with *F. regia* are common. In the series of *Berry 4545–4550* and *Falkenberg 3380–3387*, some of the individ-

uals were treated under *F. coccinea*, but several of them show signs of introgression with *F. regia*, such as leaves that are larger or more coriaceous and rounder-based than individuals of isolated populations of *F. coccinea*. The collections cited above are clearly intermediate between the two species in key characters, such as petiole length, degree of leaf pubescence, and leaf shape. Both species are tetraploid in this locality, and the one hybrid examined cytologically was tetraploid with normal bivalent formation.

Both species are also known together from the Pico do Itambé, farther north in the Serra do Espinhaço. Although the collections of *Anderson et al. 35832* and *Furlan et al. 3058* were treated under *F. coccinea*, they both have unusually thick leaves for that species, as well as rounded rather than cordate leaf bases; these traits may be the result of introgression with sympatric populations of *F. regia*.

6. *F. regia* subsp. *regia* × *F. glazioviana*

Specimens examined. BRAZIL. RIO DE JANEIRO: Morro da Nova Caledônia, outskirts of Nova Friburgo, 1,810–1,950 m, *Berry et al. 4424*, *4427* (MO, RB), *4429* (RB), *4430* (MO, RB; $n = 22$).

As in the previous two cases, *F. glazioviana* is a local, high-elevation endemic that is sympatric with *F. regia* near the former's lower altitudinal limits. *Fuchsia glazioviana* has small, densely packed leaves and smaller, narrower flowers than *F. regia*. Most of the hybrids were found along roadsides in cleared areas, and one large patch of variable individuals was seen in an exposed area near the upper limit of the cloud forest. Local populations of both species are tetraploid, as was the one intermediate individual counted.

7. *F. regia* subsp. *serrae* × *F. regia* subsp. *regia*

Specimens examined. BRAZIL. SÃO PAULO–RIO DE JANEIRO BORDER AREA: Reserva Florestal da Bocaina, *Sucre et al. 2932* (AAU, MO, RB, US); Serra da Bocaina, road to old Estação de Fruticultura (now IBDF park HQ), *Duarte 7689* (MO, RB); *Handro 807* (SP); *Ramamoorthy & Vital 1176* (MO; $n = 44$); Bananal, Rio Bonito, Serra da Bocaina, 1,000–1,100 m, *Martinelli et al. 7779* (RB); Bananal, Sertão do Rio Vermelho, E of Bocaina, *Brade 15269* (RB); Sertão Bocaina, *Pabst 4744* (MO).

Populations of *F. regia* subsp. *serrae* and subsp. *regia* converge and intergrade extensively on the upper, seaward slopes of the Serra da Bocaina, close to the Rio de Janeiro–São Paulo border. *Fuchsia regia* subsp. *regia* reaches its southernmost limits in the Serra da Bocaina, occurring mostly at altitudes of 1,100–1,550 m on both sides of the Serra. *Fuchsia regia* subsp. *serrae* occurs exclusively on the lower, seaward slopes of the same range between 500 and 1,150 m, part of an almost continuous distribution down the coastal slopes of the Serra do Mar and Serra Geral as far as Rio Grande do Sul.

Varied intermediate forms between the two subspecies occur between 1,150 and 1,350 m on the upper slopes of the Serra da Bocaina, along the road from Cunha to Paraty. Most of the fuchsias in this area, including those cited in the above list, are unusually pubescent for *F. regia*. The degree of sepal connation and the thickness and persistence of the stipules, which generally distinguish these taxa, vary widely between individuals in this area, whereas populations higher up on the Serra and further inland are largely glabrous and fall well within the normal range of variation of *F. regia* subsp. *regia*. Hoshino & Berry (1989) reported tetraploid and octoploid individuals of *Fuchsia* from this area, further indicating the intergradation of the basically octoploid subsp. *serrae* and the mostly tetraploid subsp. *regia*. Hexaploid hybrids should be sought in mixed populations.

Although *F. regia* subsp. *regia* is not found further south in São Paulo, more populations of aberrant or intermediate individuals occur as far south as the Serra do Mar above Ubatuba, approximately 60 km south of the Bocaina massif. Tetraploid and octoploid individuals occur side by side at the Alto da Serra near the crest of the mountain (Hoshino & Berry, 1989), again with the unusual pubescence for *F. regia* and considerable variability in such traits as the degree of stipule development. In most other features, however, these individuals resemble *F. regia* subsp. *serrae* more closely than subsp. *regia*.

8. *F. regia* subsp. *serrae* × *F. regia* subsp. *reitzii*

Specimens examined. BRAZIL. SANTA CATARINA: top of Serra Geral and escarpments, km 22–25 from Lauro Müller to Bom Jardim da Serra, 1,270–1,450 m, *Berry et al. 4517*, *4519* (MBM, MO); *Falkenberg 2302* (FLOR); Rio Caveiras a Lajes, *Lutz in 29 Dec. 1949* (R #116687); Serra da Rocinha, border of Santa Catarina and Rio Grande do Sul, 1,250–1,280 m, 22 km above Timbé do Sul, *Falkenberg et al. 3762* (FLOR, MO; the whole series of *Falkenberg et al. 3756–3766* is a variable series of mostly intermediate variants); *Rambo 4604* (PACA); NW of Uribici, km 90 of road to Braço do Norte, 950 m, *Falkenberg et al. 3784* (FLOR, MO). RIO GRANDE DO SUL: Itaimbezinho, Aparados da Serra, *Falkenberg 261*, *264*, *275*, *354*, *357* (FLOR); *Pirani & Yano 839* (SP); *Rambo 49363*, *50150* (PACA); Caracol, near Canela, *Emrich in Feb. 1951* (PACA 50187); *Lindeman & Haas s.n.* (ICN #21790); 18 km N of Canela, Salto da Ferradura, *Schultz s.n.* (ICN #21032); Bom Jesus, *Fal-*

kenberg 1150 (FLOR); Taimbé, São Francisco de Paula, *Rambo 49363* (SI); Fazenda Bernardo Velho, Aparados da Serra, Bom Jesus, *Rambo 34864* (SI).

Both of these two subspecies are morphologically and ecologically distinct over most of their ranges, with *F. regia* subsp. *reitzii* confined to thickets in the southern planalto and *F. regia* subsp. *serrae* inhabiting the wet, seaward slopes of the coastal mountain ranges. *Fuchsia regia* subsp. *serrae* has nitid, subcoriaceous leaves with thick stipules and flowers with strongly connate, recurved sepals, while subsp. *reitzii* has thinner, more whorled leaves with serrate margins, thin stipules, and flowers with spreading, slightly connate sepals.

A narrow ecotone occurs all along the crest of the Serra do Mar and the Serra Geral in Santa Catarina and Rio Grande do Sul as the high rolling plains end and the steep coastal ranges drop abruptly to the Atlantic lowlands. Along this belt, which occurs sometimes just at the crest of the ridges and other times extends a few hundred meters or several kilometers inland, the two subspecies of *F. regia* converge and intergrade in a bewildering variety of variants, some of them exceeding the normal limits of variation of either parental subspecies.

The narrowest ecotone observed was at the Serra da Rocinha, on the Santa Catarina–Rio Grande do Sul border. In this area, the planalto is covered right to the edge by grassy campos, followed by steep drop-offs covered by a special "Aparados" flora adapted to the persistent rains and mists from the rising coastal air masses (Rambo, 1956). Along the rim of the serra cliffs, between 1,250 and 1,280 m, hybrid swarms of *F. regia* subsp. *serrae* and *reitzii* occur together with occasional plants that can be distinguished as parental, such as those included in the collection series of *Falkenberg et al. 3756–3766.*

Other areas where similar series of intermediates have been observed and collected include the Aparados da Serra at Itaimbezinho, in Rio Grande do Sul, and the area around the crest of the Serra Geral between Bom Jardim da Serra and Lauro Müller in Santa Catarina. Near the town of Urubici, Santa Catarina, plants of *F. regia* subsp. *serrae* occur farther inland from the crest of the Serra Geral, around the base of the Morro da Igreja and Campo dos Padres, the highest points in Santa Catarina. Where the two subspecies occurred sympatrically, as in the collection series of *Falkenberg et al. 3787–3791* (FLOR, MO; just W of the crest of the ridge between Urubici and Braço do Norte, at 1,030 m), some unusual variants of subsp. *serrae* were found with flowers less than half the normal size (*#3790*).

Both subspecies are octoploid and are characterized by variable numbers of multivalents during meiotic metaphase (Hoshino & Berry, 1989); the one intermediate individual examined had the same chromosome number and type of meiotic configuration.

OBSERVATIONS ON POLYPLOIDY IN *FUCHSIA* SECTS. *QUELUSIA* AND *KIERSCHLEGERIA* (ONAGRACEAE)[1]

Takuji Hoshino[2] *and Paul E. Berry*[3]

ABSTRACT

Chromosome numbers are reported for all eleven taxa currently recognized in *Fuchsia* sect. *Quelusia* and for *F. lycioides*, the sole member of sect. *Kierschlegeria*. Results are based on the study of individuals from 103 native populations and 13 cultivated plants. Most species and sections of *Fuchsia* are diploid ($n = x = 11$), but sects. *Quelusia* and *Kierschlegeria* are entirely polyploid, including the only naturally occurring octoploids in the genus. Polyploidy in these sections is always associated with 3(4)-aperturate pollen grains, instead of the normal 2-aperturate condition in the genus. All chromosome counts obtained from *F. lycioides* and from seven of the nine species in sect. *Quelusia* were tetraploid, but intraspecific variation in ploidy level was found in two Brazilian species of sect. *Quelusia*. The only wild individual examined of *F. alpestris* was tetraploid, whereas a cultivated specimen of this species from Europe was octoploid. In the widespread, polytypic *F. regia*, all individuals examined of subspecies *reitzii* and *serrae* were octoploid, but both tetraploid and octoploid populations were found in subsp. *regia*. Both ploidy levels were also found in the extreme northern range of subsp. *serrae*, in individuals that were morphologically intermediate with subsp. *regia*. This situation suggests that octoploidy has evolved recently and possibly repeatedly in sect. *Quelusia*, whereas tetraploidy probably originated in a common ancestor to sects. *Quelusia* and *Kierschlegeria*.

Fuchsia is one of the largest genera of the Onagraceae, with over 100 species occurring mostly in tropical montane cloud forests. It is placed in its own tribe, Fuchsieae, on the basis of its fleshy fruits and mostly 2-aperturate pollen. Chromosomes in *Fuchsia* are large and are heterogeneous in size for the family, with interphase nuclei having pycnotic areas that are variable in number, size, and density (Kurabayashi et al., 1962); these are unspecialized features shared with *Lopezia* and *Circaea*. All species examined in the genus have the basic chromosome number of the family, $x = 11$ (Raven, 1979), and none have the translocation systems or aneuploidy that are characteristic of other onagraceous genera such as *Oenothera* and *Clarkia*.

In recent efforts to improve our understanding of the relationships of the different species and sections of *Fuchsia*, the distribution of chromosome numbers has been determined for as many species as possible in the genus, together with extensive surveys of the palynology and foliar flavonoid chemistry of most taxa (Nowicke et al., 1984; Averett et al., 1986). To date, diploid chromosome counts ($n = 11$) have been obtained for 69 species and tetraploid counts ($n = 22$) for 10 species (Breedlove, 1969; Breedlove et al., 1982; Berry, 1982, 1985; Berry et al., 1988; Hoshino & Berry, 1988). Of the ten sections currently recognized in the genus (Berry et al., 1988), six are entirely diploid. The two largest sections, *Fuchsia* (61 species) and *Hemsleyella* (14 species), are predominantly diploid, but sect. *Fuchsia* has six known tetraploid or partly tetraploid species (Berry, 1982), and sect. *Hemsleyella* has two tetraploid species (Berry, 1985). This paper presents the results of

[1] Supported by grants to P. Berry by the American Philosophical Society, the Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICIT, Venezuela), the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq, Brazil), as well as a U.S. National Science Foundation grant to Peter H. Raven. We are especially grateful to T. P. Ramamoorthy for making the initial chromosome counts in this study and to C. Marticorena, who made an extensive transect in Chile to collect seeds of many *Fuchsia* populations. Live seeds or fixed buds were also kindly sent to us by J. Diem, E. Pisano, D. Reiman-Dietiker, and E. Riquelme. We also thank D. Falkenberg, P. Goldblatt, and P. Raven for helpful comments on a draft of this paper.

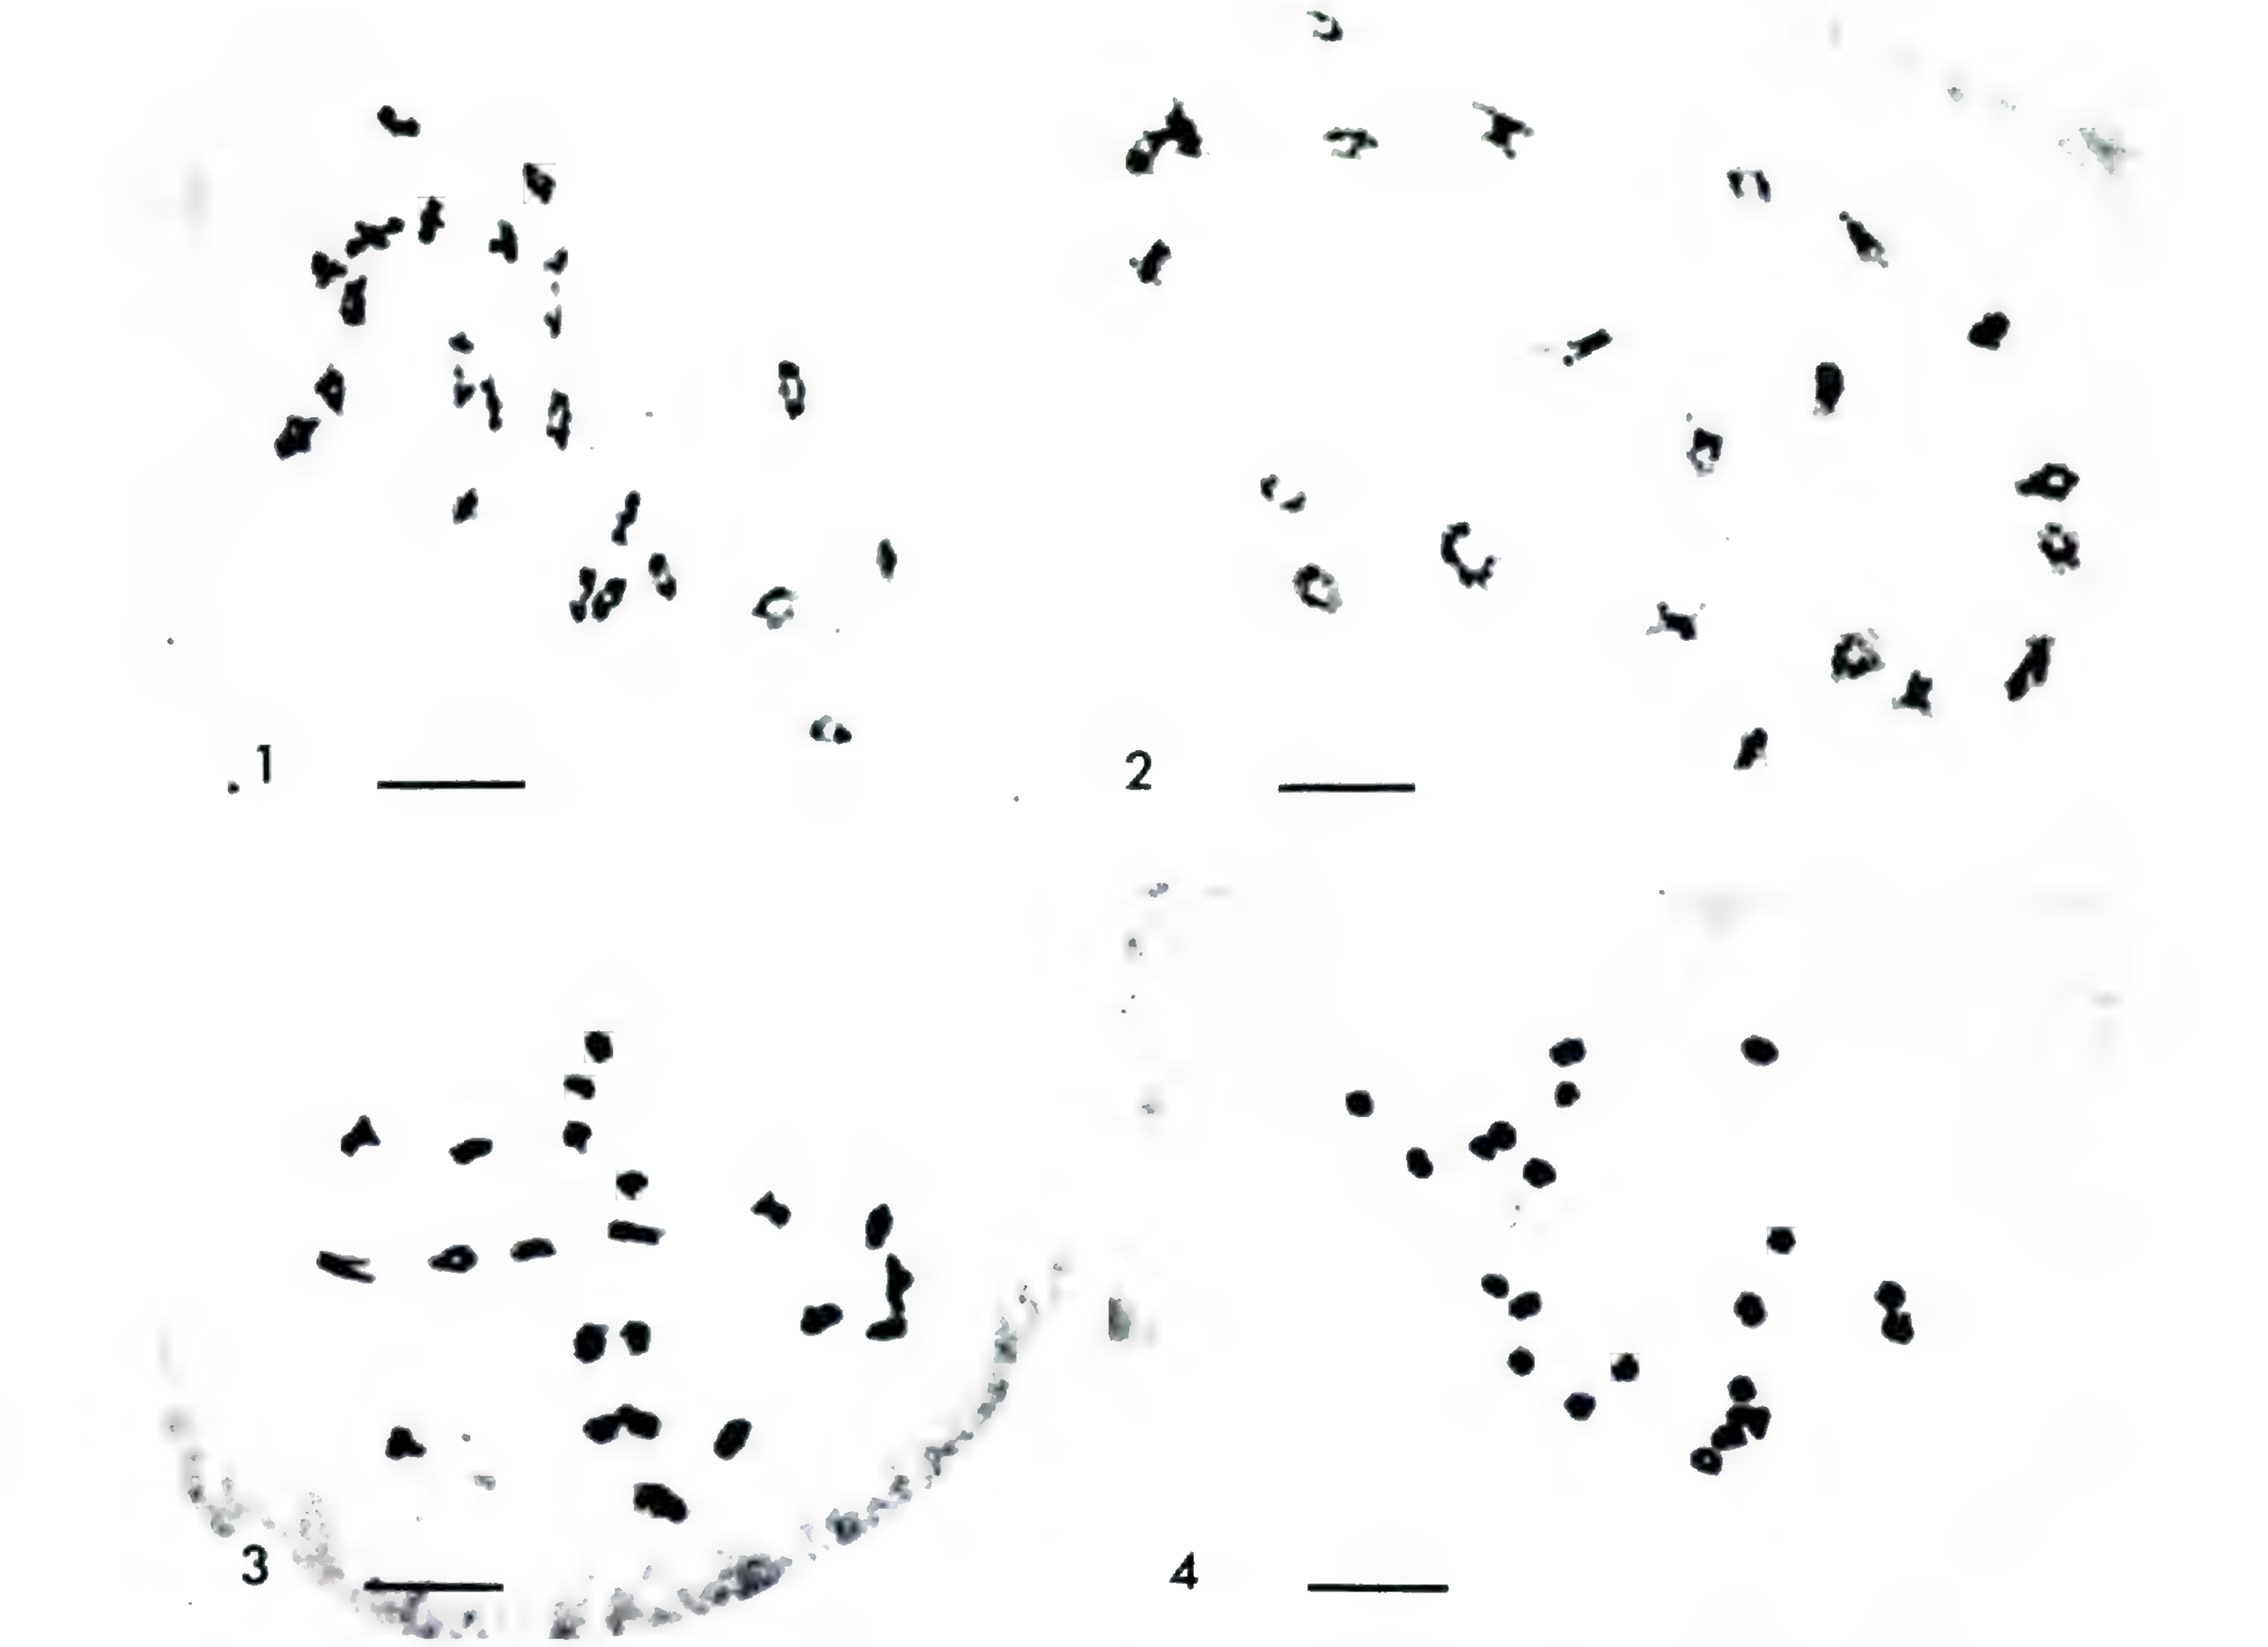
TABLE 1. Summary of chromosome numbers in *Fuchsia* sect. *Quelusia*.

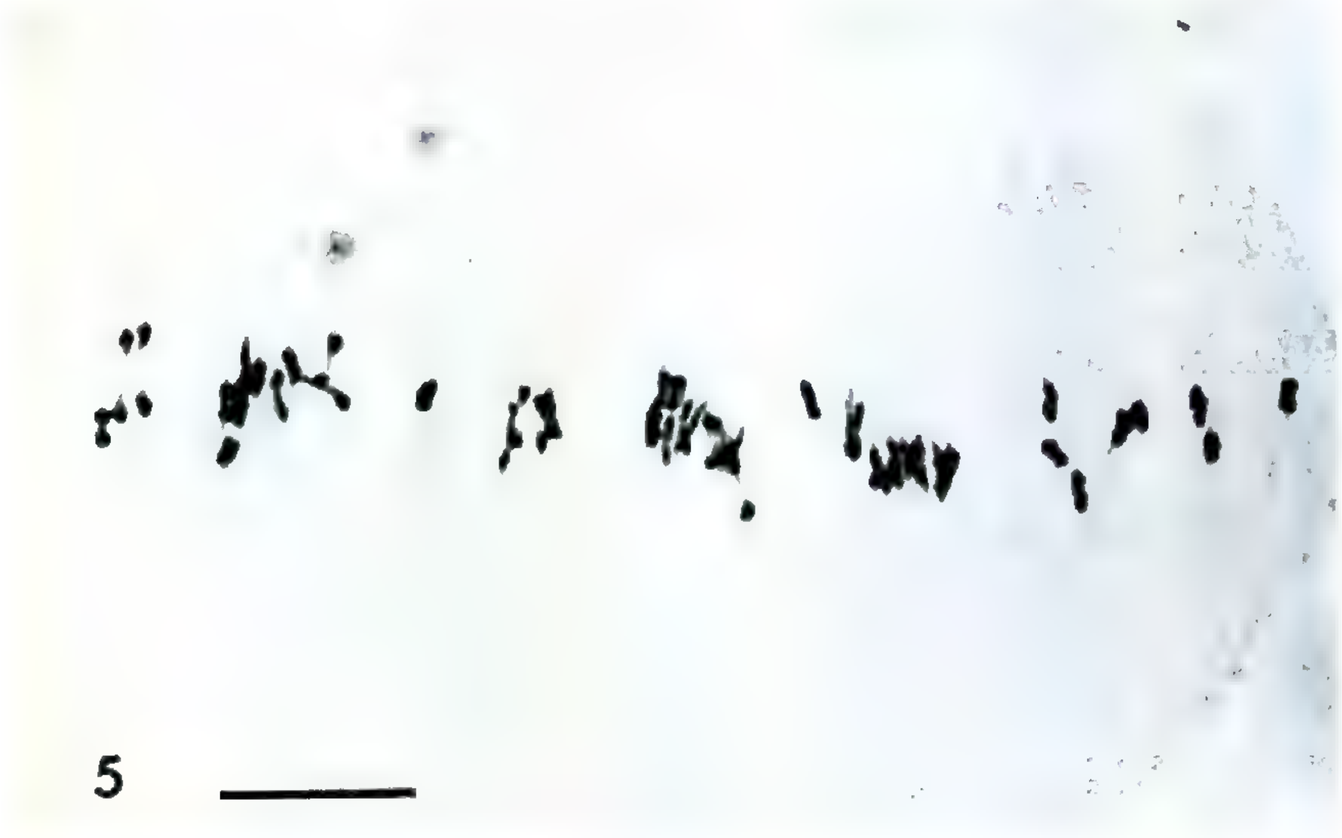
Taxon	Gametic Chromosome Number
F. alpestris Gardner	22, 44
F. bracelinae Munz	22
F. brevilobis P. Berry	22
F. campos-portoi Pilger & Schulze	22
F. coccinea Dryander	22
F. glazioviana Taubert	22
F. hatschbachii P. Berry	22
F. magellanica Lamarck	22
F. regia (Vellozo) Munz subsp. *regia*	22, 44
F. regia subsp. *reitzii* P. Berry	44
F. regia subsp. *serrae* P. Berry	44

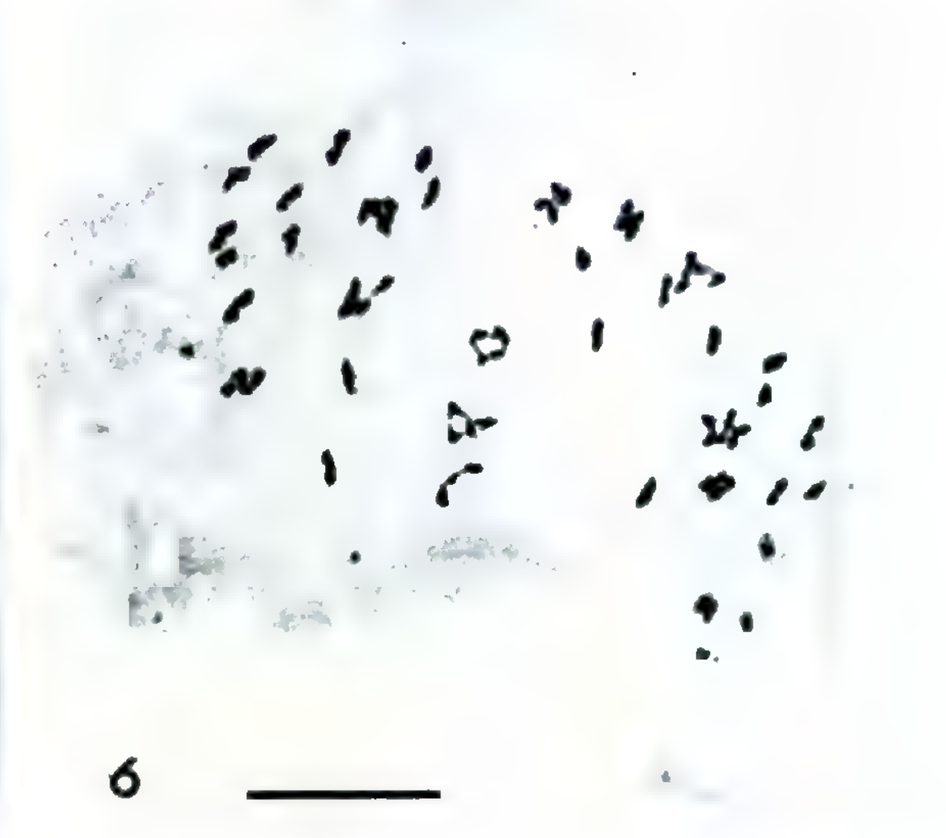
a comprehensive survey of the cytology of all 11 taxa of sect. *Quelusia*, concurrently with a systematic revision of the section (Berry, 1989). It also presents the first published counts for *Fuchsia lycioides*, the sole member of sect. *Kierschlegeria*.

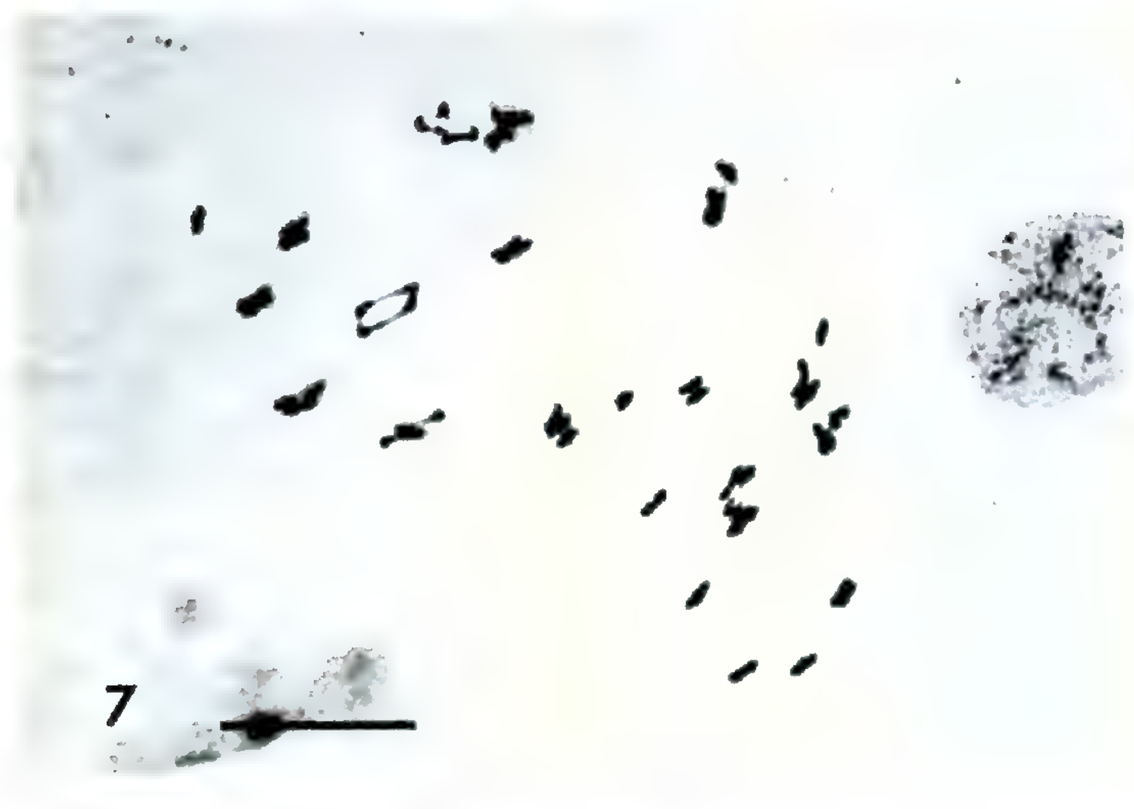
The only previous reports on chromosomes in sect. *Quelusia* were from *F. magellanica*. The first report by Warth (1923) was $n = 22$ for *F. coccinea*, but photographs in a subsequent publication (Warth, 1925) showed that this was a misidentification of *F. magellanica*. Johanssen (1929a, b) reported diploid counts of $n = 11$ for two horticultural selections of *F. magellanica*, but no vouchers or illustrations were provided to verify the identity of his plants, which were very likely misidentified (P. Raven, pers. comm.). A report of $2n = 44$ in *F. magellanica* by Haque (1952) also lacked vouchers. Chaudhuri (1956) made counts of $n = 22$ in *F. magellanica* and noted that it had



FIGURES 1–4. Photomicrographs of meiotic chromosomes of *Fuchsia* sect. *Quelusia*.—1. Metaphase I in *F. bracelinae* (*Berry et al. 4524*). $2n = 44$ (22II).—2. Diakinesis in *F. campos-portoi* (*Berry et al. 4435*). $2n = 44$ (22II).—3. Metaphase I in *F. coccinea* (*Berry et al. 4458*). $2n = 44$ (22II).—4. Metaphase I in *F. regia* subsp. *regia* (*Berry et al. 4544*). $2n = 44$ (22II). Scale bars = 10 μm.







FIGURES 5–8. Photomicrographs of meiotic metaphase chromosomes of *Fuchsia* sect. *Quelusia*.—5. *Fuchsia regia* subsp. *reitzii* (*Berry & Falkenberg 4510*). $2n = 88$ (15IV & 14II).—6. *Fuchsia regia* subsp. *serrae* (*Berry et al. 4492*). $2n = 88$ (9IV & 26II).—7. *Fuchsia regia* subsp. *serrae* (*Berry et al. 4493*). $2n = 88$ (17IV & 10II).—8. *Fuchsia regia* subsp. *reitzii* (probable hybrid with subsp. *serrae*, from *Berry & Falkenberg 4517*). $2n = 88$ (15IV & 14II). Scale bars = 20 μm.

distinctly shorter chromosomes than several diploid species he examined in the genus. Kurabayashi et al. (1962) examined two different collections of *F. magellanica*, which they also found to be tetraploid with short chromosomes. Although Chaudhuri (1956) reported a tetraploid count for *F. lycioides*, no voucher specimens were provided, and his description of this entity clearly indicates that it was a hybrid, probably of *F. magellanica* × *F. lycioides* parentage.

Materials and Methods

Meiotic chromosomes were examined in pollen mother cells of young buds fixed in Carnoy's solution (3 : 1 absolute ethanol to glacial acetic acid) for 24 hours, then transferred to 70% ethanol for storage. Anthers were squashed in 1% aceto-orcein.

Somatic chromosomes were studied in root tip apices, which were pretreated in 0.002 M aqueous 8-hydroxyquinoline for 6 hours at 5°C, then fixed in Carnoy's solution and macerated in 10% HCl for 6 minutes at 60°C. The root tips were stained in 1% aceto-orcein for 10 or 20 minutes and then squashed.

To establish pollen fertility, pollen grains were stained with Alexander's solution (Alexander, 1969).

Results

Chromosome counts from 40 different populations of native and cultivated individuals of *F. magellanica* were consistently tetraploid ($n = 22$; Table 1, Appendix). The populations sampled covered most of the range of this widespread species of southern Argentina and Chile, leaving little doubt that it is cytologically uniform throughout its range.

Counts of all other taxa in sect. *Quelusia* represent their first validated chromosome reports (Table 1). Seven Brazilian species, including the newly described *F. brevilobis* and *F. hatschbachii* (Berry, 1989), are all tetraploid, based on at least two counts for each species. The Chilean *F. lycioides*

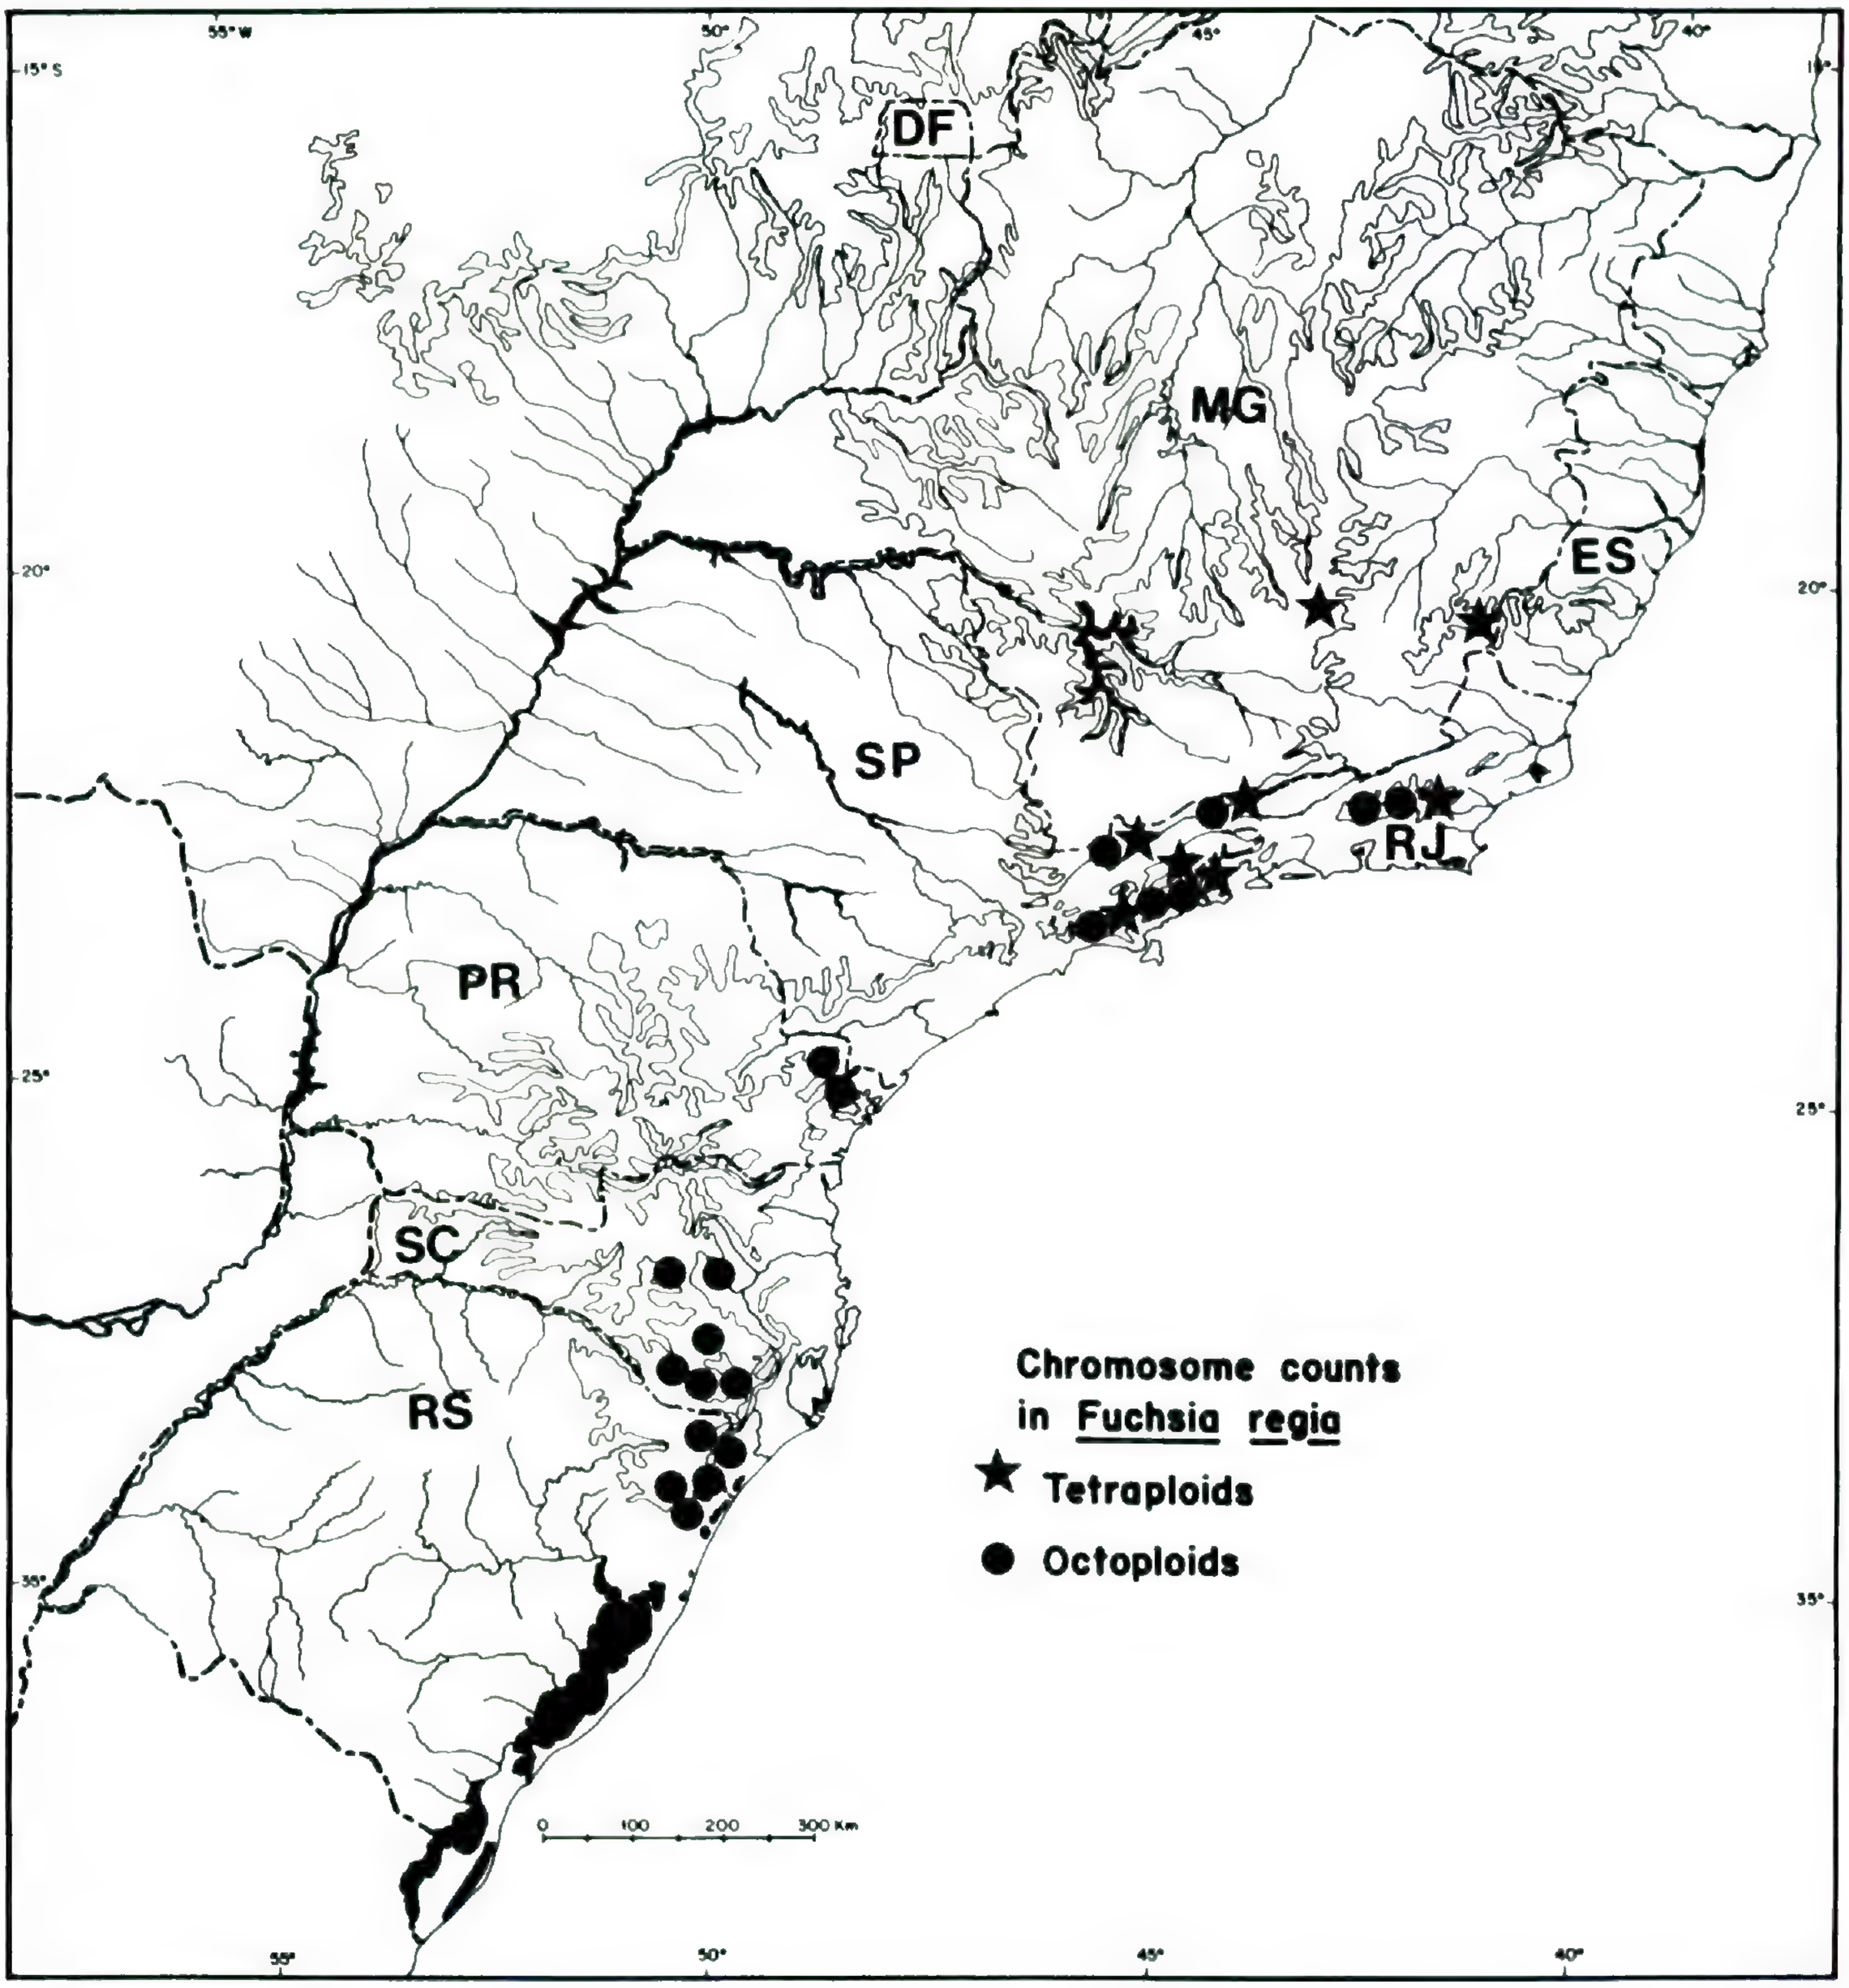


FIGURE 9. Geographical distributions of the different cytotypes of *Fuchsia regia* in southeastern Brazil. Pairs of capital letters refer to state abbreviations, RJ = Rio de Janeiro, etc. Contour lines indicated at 800 m.

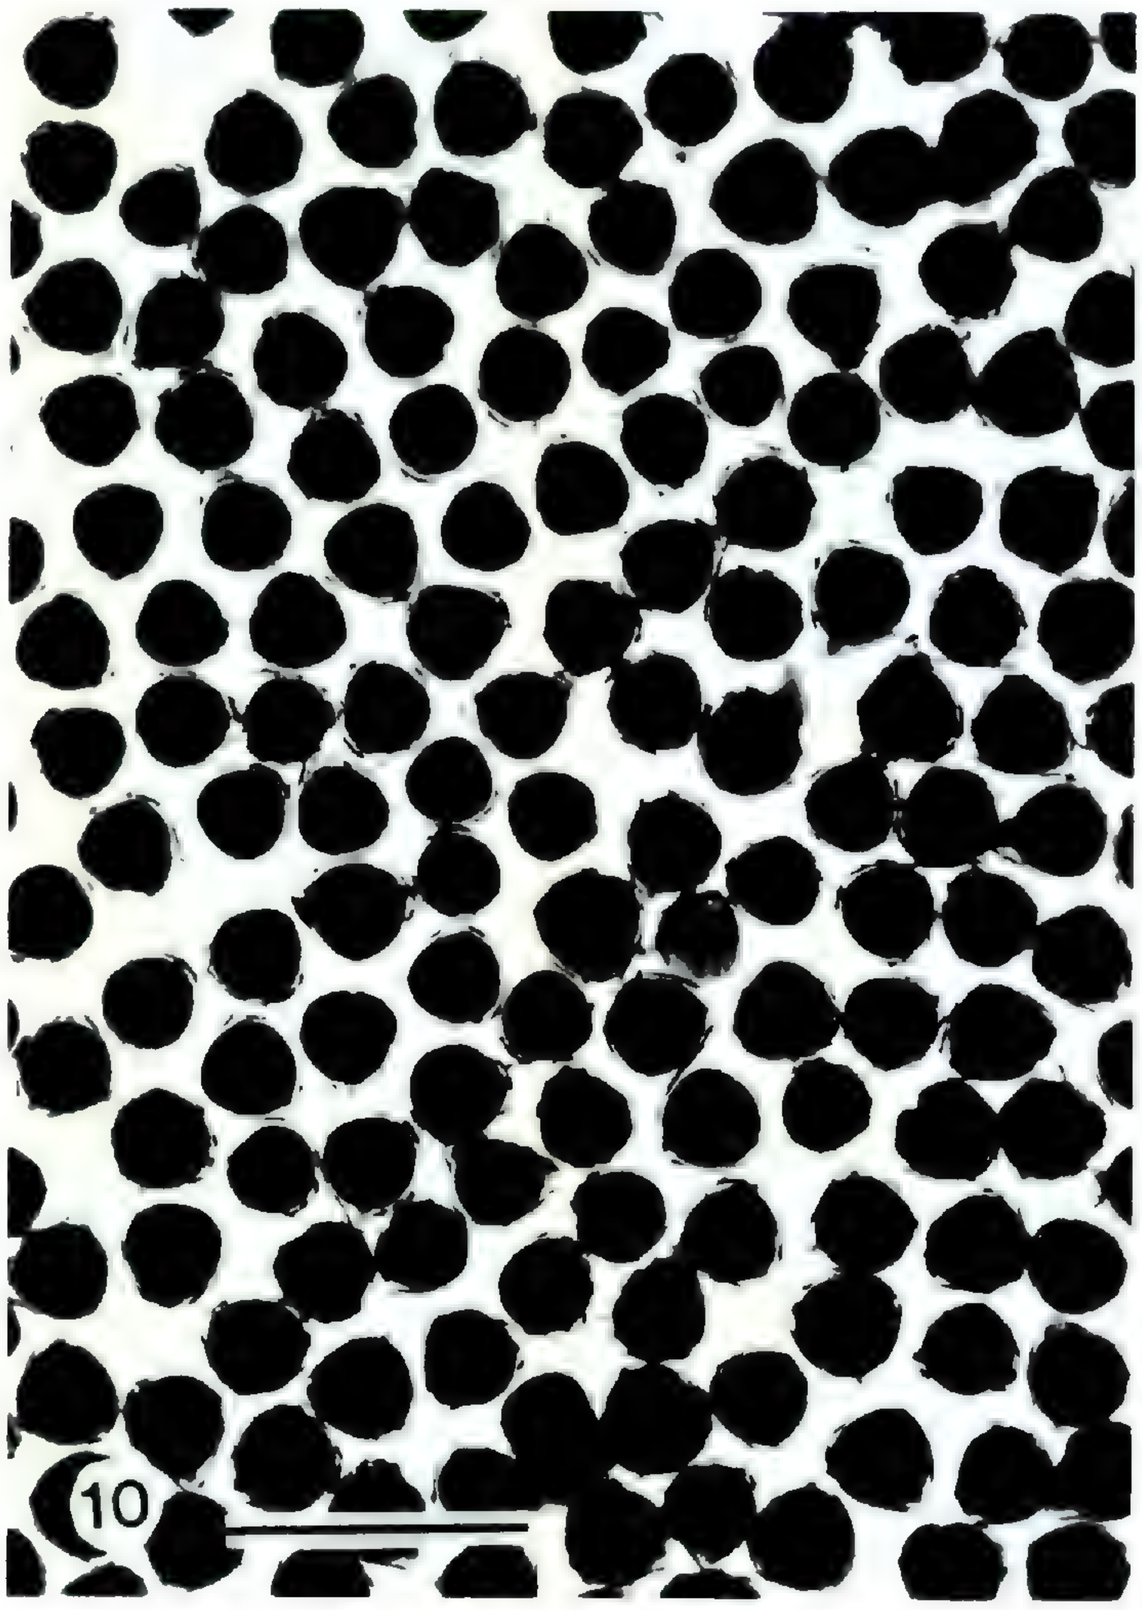
(sect. *Kierschlegeria*) is also tetraploid. Normal bivalent formation was found in all tetraploid collections examined (Figs. 1–4). In the Brazilian *F. alpestris*, the single naturally occurring individual counted was tetraploid, but a plant of this species cultivated in Europe was octoploid.

Fuchsia regia, the most widespread species of the genus in Brazil, has tetraploid and octoploid populations (see Appendix). Populations from the southern half of its range were entirely octoploid, including all populations counted of subspecies *reitzii* and *serrae* and one naturally occurring hybrid between them. In most of the octoploids, numerous quadrivalents and bivalents were formed (Figs. 5–8).

Populations of *F. regia* subsp. *regia* with both tetraploid and octoploid individuals were found in northern São Paulo and southern Rio de Janeiro states (Appendix, Figure 9). The southernmost tetraploid individuals of *F. regia* came from north-central São Paulo State. These collections are morphologically intermediate, probable hybrids between subspecies *regia* and *serrae*. They also occurred sympatrically with octoploid individuals



FIGURES 10, 11. Photomicrographs of pollen grains from *Fuchsia* sect. *Quelusia*.—10. *Fuchsia regia* subsp. *serrae* ($2n = 88$) (*Ramamoorthy & Hatschbach 830*).—11. *Fuchsia regia* subsp. *regia* × *F. regia* subsp. *serrae* ($2n = 66$), artificial hybrid between *Ramamoorthy 683* (subsp. *regia*, $2n = 44$) and *Ramamoorthy & Hatschbach 830* (subsp. *serrae*, $2n = 88$), cultivated at Missouri Botanical Garden, *M2588*. Scale bars = 150 μm.

of *F. regia* subsp. *serrae*, but no hexaploid individuals were found in these areas. In Minas Gerais and other parts of Rio de Janeiro, all populations of subsp. *regia* sampled were tetraploid. The distribution of the different cytotypes of *F. regia* is shown in Figure 9.

Although meiosis was not observed in an artificial hexaploid hybrid between a tetraploid plant of *F. regia* subsp. *regia* and an octoploid one of subsp. *serrae*, more than 50% of the pollen grains of the hybrid were aborted. Both parents, however, showed fully stained and apparently viable pollen grains (Figs. 10, 11).

DISCUSSION

Sections *Kierschlegeria* and *Quelusia* are the only entirely polyploid sections of *Fuchsia*. In both groups, polyploidy is associated with 3-aperturate pollen, considered to be derived from the more common 2-aperturate condition in the genus (Nowicke et al., 1984). Despite differences between the two sections in viscin thread type (Nowicke et al., 1984), seed number and anatomy, sexual systems, and other morphological features (Berry, 1982), a preliminary chloroplast DNA restriction site analysis by Sytsma & Smith (1988) has shown the two sections to be more closely related to one another than to any other section of the genus. The results of a separate cladistic analysis of the species of these two sections by Berry (1989) were consistent with the hypothesis that tetraploidy evolved in a common ancestor. Since the other eight sections of the genus are predominantly diploid, including the South Pacific sect. *Skinnera* and all four Central American sections, it is clear that no existing member of sect. *Quelusia* or sect. *Kierschlegeria* could have directly given rise to those groups.

Octoploidy in natural populations of *Fuchsia* is known only in sect. *Quelusia*, where it has been detected primarily in *F. regia*, a species that also has tetraploid populations. Quadrivalents are common in the octoploid individuals examined, indicating a close chromosomal homology between the genomes that came together. Both the presence of different ploidy levels and the varying numbers of multivalents in *F. regia* indicate a recent origin of octoploidy in the genus. Whether the octoploidy detected in *F. alpestris* originated naturally or

under cultivation is not known, but the extent of the two different chromosome numbers needs to be examined further in nature. Cases of intraspecific polyploidy are widespread in the Onagraceae and have been recorded in over 40 species and 11 genera (Lewis, 1979).

The high level of pollen abortion in the artificial hexaploid between a tetraploid and an octoploid subspecies of *Fuchsia regia* is indicative of irregularities in meiotic pairing and disjunction, which may explain the absence of naturally occurring hexaploids among the individuals sampled in areas where tetraploids and octoploids both were found. Areas where tetraploid and octoploid populations of *F. regia* are known to occur sympatrically, such as the Serra da Bocaina and Campos do Jordão in northern São Paulo state, and the Itatiaia massif and the Serra dos Órgãos in Rio de Janeiro, should be sampled more intensively for naturally occurring hexaploids.

Within the Onagraceae, the pattern of polyploidy in *Fuchsia* sect. *Quelusia* is most similar to that of *Ludwigia*, where polyploidy has been a frequent and important part of the evolutionary strategy in most of the genus, with numerous cases of intraspecific polyploidy (Raven & Tai, 1979). Unlike the situation in tribe Onagreae, where polyploidy is associated with autogamy and aneuploidy in annual species, aneuploidy is unknown in *Fuchsia* and *Ludwigia*, and polyploid taxa are perennial and predominantly outcrossing. This clearly shows that the effects of polyploidy can vary widely in related genera, depending on factors such as the longevity of the species and the habitat in which they occur.

Fuchsia regia subsp. *regia* × *F. regia* subsp. *serrae* ($2n = 66$).

Artificial hybrid between *Ramamoorthy 683* (subsp. *regia*, $n = 22$) and *Ramamoorthy & Hatschbach 830* (subsp. *serrae*, $n = 44$), cultivated at Missouri Botanical Garden, *M2588*.

NOTES ON THE *CORDIA PANAMENSIS* COMPLEX (BORAGINACEAE) AND A NEW SPECIES FROM COLOMBIA

Cordia is a large pantropical genus of about 300 species, divided by most recent authors into six sections (Nowicke & Miller, in press). Section *Myxa*, with over 150 species, is the largest in the Neotropics and includes all but one of the paleotropical species (Miller, 1985). It is difficult taxonomically because most of the groups that can be recognized within the section have obscure boundaries.

One such group is the *Cordia panamensis* Riley group (Miller, 1985), which is widespread in Central America, the West Indies, and northern South America. This group is particularly problematic in terms of its definition within sect. *Myxa*, as well as species delimitations within it. It is loosely defined and may very well not be monophyletic, yet the species all share a similar appearance and are often confused in herbaria. The *C. panamensis* group is characterized by ovate to lanceolate, scabrous to scabrid, usually anisophyllous leaves that generally dry brown. All of the species except *C. anisophylla* J. S. Miller are dioecious. Perhaps *C. bicolor* A. DC. and *C. sellowiana* Cham. should be included, but *C. bicolor* does not dry brown, and both species differ in being homostylous.

Sculpturing on the surface of the endocarps appears to be useful in distinguishing species of *Cordia* sect. *Myxa* (Miller, in prep.) but has not yet been used for this. Dried fruits of various species of the *C. panamensis* group were soaked in 5% NaOH for two days to soften the exocarp and mesocarp, then washed in running water to remove outer tissues and expose the cleaned, outer surface of the endocarp. *Cordia gentryi* has an endocarp with raised, quadrangular areas (Fig. 1C); in *C. anisophylla* the raised areas are much longer (Fig. 1D). Other members of the group have rugulose (*C. panamensis*, Fig. 1E) to spinulose (*C. hebeclada* I. M. Johnston, Fig. 1F) endocarps.

Recent studies of members of the *C. panamensis* group have helped clarify the relationships of species in Central America (Miller, 1985, 1988) and Venezuela (Gaviria, 1987). The group is defined here as consisting of ten species, but problems still exist with differentiating *C. panamensis* and *C. macrophylla*. I have seen little material of *C. macrophylla* and have maintained it as separate following Johnston (1949). As part of a review of the *C. panamensis* group, several novel collections from Pacific coastal Colombia appear to represent an undescribed species.

KEY TO THE SPECIES OF THE *CORDIA PANAMENSIS* GROUP

1a. Leaf apices acute to obtuse.
  2a. Stems, petioles, and inflorescence branches with echinate hairs ..... *C. cymosa* (J. D. Smith) Standley
  2b. Stems, petioles, and inflorescence branches with simple hairs.
    3a. Petioles longer than 15 mm; twigs puberulent to strigillose; South America ..... *C. tetrandra* Aubl.
    3b. Petioles shorter than 15 mm; twigs velutinous to hirsute; West Indies ..... *C. sulcata* DC.
1b. Leaf apices acuminate to caudate.
  4a. Twigs strigillose, the hairs appressed, short, white or translucent.
    5a. Flowers distylous; corollas longer than 10 mm; mature fruits ellipsoid, longer than 8 mm ..... *C. anisophylla* J. S. Miller
    5b. Flowers dioecious; corollas shorter than 5 mm; mature fruits ovoid, shorter than 8 mm ..... *C. sericicalyx* DC.
  4b. Twigs with erect or curly hairs or densely short-velutinous, or if strigillose, the hairs brown.
    6a. Leaf apices caudate; mature fruits longer than 14 mm, glabrous ..... *C. gentryi* J. S. Miller
    6b. Leaf apices acuminate; fruits shorter than 14 mm or puberulent.
      7a. Branches of the inflorescences ferruginous-tomentose; fruits puberulent ..... *C. toqueve* Aubl.
      7b. Branches of the inflorescence velutinous to hirsute; fruits glabrous.
        8a. Stems hirsute to hispid.
          9a. Twigs shaggy-velutinous; Jamaica ..... *C. macrophylla* L.
          9b. Twigs hirsute; Mexico to South America, Trinidad, and Tobago ..... *C. panamensis* Riley

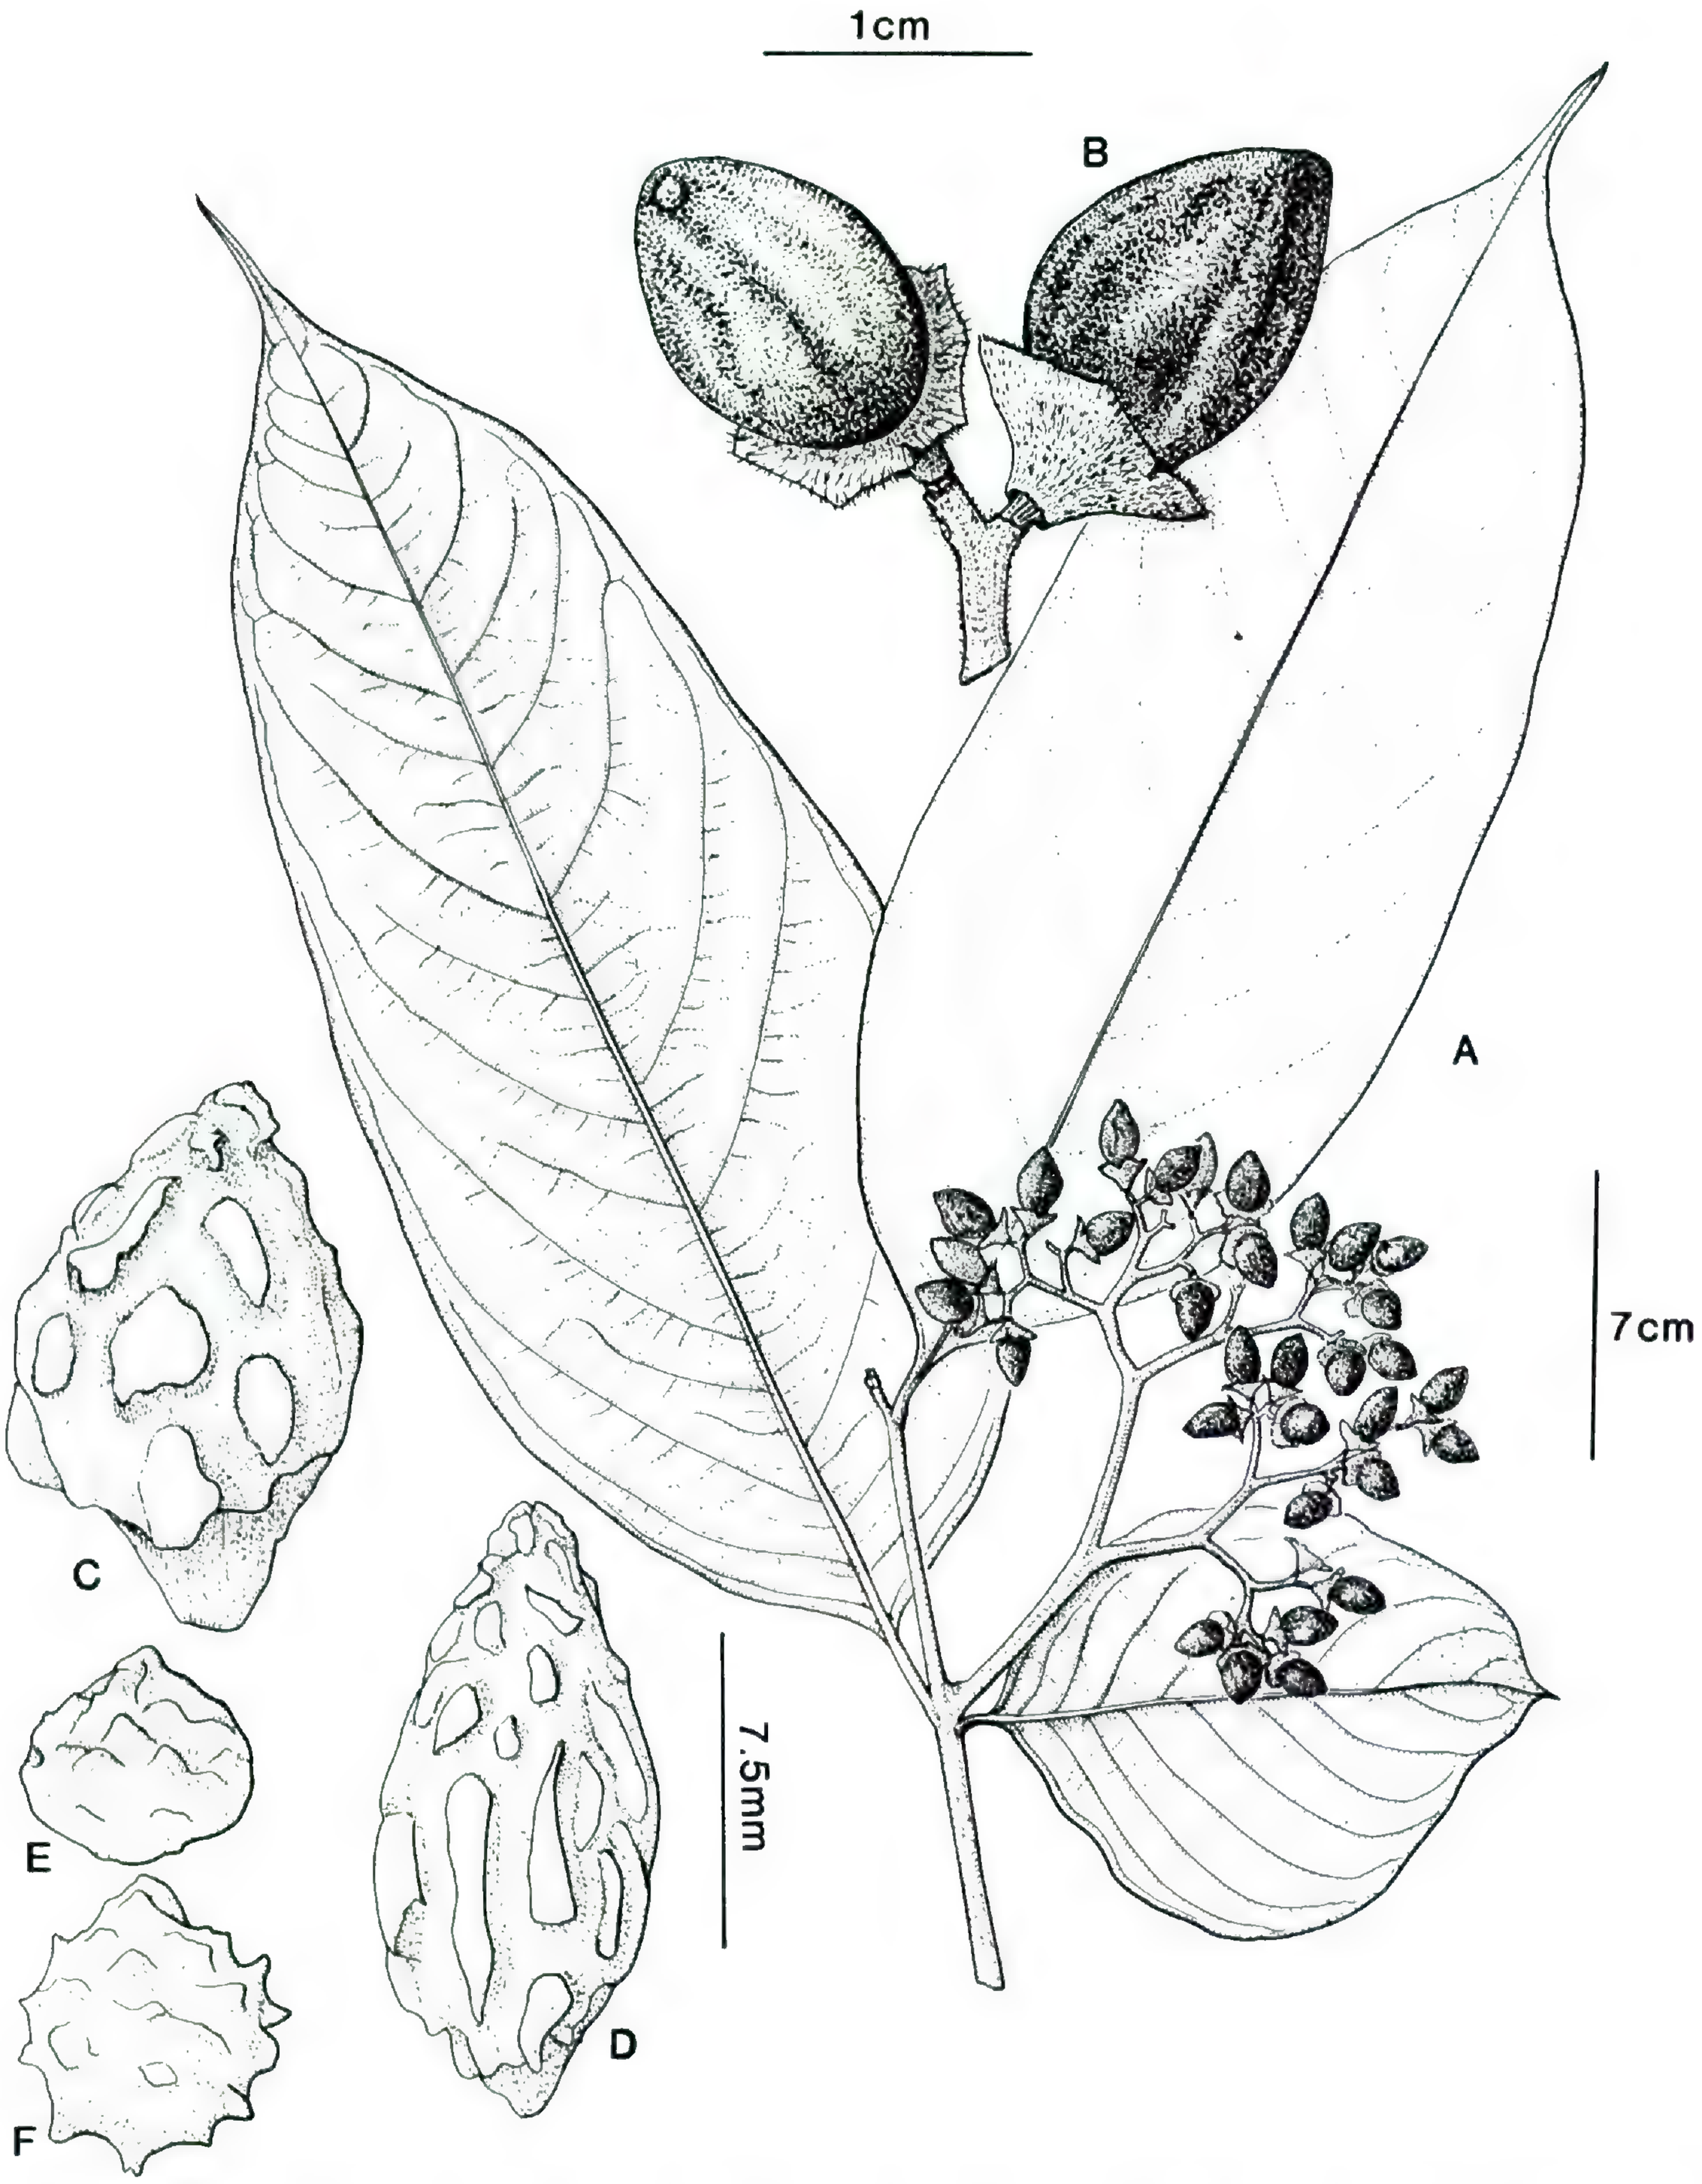

FIGURE 1. A–C. *Cordia gentryi* (*Gentry et al. 17874* (MO), Colombia).—A. Fruiting branch.—B. Fruits with persistent calyces. C. Dorsal view of endocarp. –D. *Cordia anisophylla* (*Mori & Kallunki 6373* (MO), Panama), dorsal view of endocarp.—E. *Cordia panamensis* (*Miller & Miller 961* (MO), Panama), dorsal view of endocarp. —F. *Cordia hebeclada* (*Gentry et al. 19686* (MO), Peru), dorsal view of endocarp.

8b. Stems pubescent to densely short velutinous.
9a. Fruits white; twigs hirsute to velutinous; upper leaf surface scabrous; West Indies ..... *C. sulcata* DC.
9b. Fruits yellow; twigs short and evenly golden brown velutinous; upper leaf surface glabrous to scabrid; Colombia, Ecuador, Peru ..... *C. hebeclada* I. M. Johnston

Cordia gentryi J. S. Miller, sp. nov. TYPE: Colombia. El Valle: Bajo Calima, Dindo area, 100 m, 11 July 1984, *A. Gentry, M. Monsalve & D. Wolfe 47874* (holotype, MO 3521285).

Arbor ad 8 m alta, ramunculis dense strigillosis ad puberulentis. Folia persistentia, petiolis 1.7–2.6 mm longis; laminae anisophyllae, folia maioribus ovatis, 30–35.3 cm longis, 10.7–13 cm latis, apice caudatis, basi obtusis, minoribus orbicularis, superficie scabrida, pagina inferiore grosse pubens. Flores ignoti. Fructus drupaceus, aurantiacus, endocarpo osseo, inaequilateraliter ovoideo, 16 mm longo, 10 mm lato.

Tree 8 m tall, the twigs densely puberulent with erect, brown hairs. Leaves persistent, dimorphic; petioles 1.7–2.6 mm long, canaliculate adaxially, puberulent, with erect, brown hairs; the larger blades narrowly ovate, 30–35.3 cm long, 10.7–13 cm wide, the apex caudate, 3–4 cm long, the base obtuse; smaller blades orbicular, 11–15.5 cm long, 9.5–14 cm wide, the apex abruptly short acuminate, the base rounded to acute, both types with the margin entire, the upper surface scabrous, the hairs translucent, appressed, the midrib raised, puberulent, the lower surface coarsely pubescent, with 6–10 pairs of secondary veins. Flowers unknown. Infructescence broadly cymose, ca. 13 cm broad. Fruits drupaceous, orange-yellow, the fruiting calyx slightly accrescent, unevenly 5-lobed, 9–11 mm broad, appearing torn along the margin, uniformly strigillose, somewhat sericeous inside, the mesocarp mucilaginous, the endocarp bony, inequilaterally ovoid, 16 mm long, 10 mm broad, the surface reticulate with raised quadrangular areas.

Distribution. *Cordia gentryi* is known from the Colombian provinces of Chocó and El Valle at elevations below 100 m in wet tropical forests.

Additional specimens examined. COLOMBIA. CHOCÓ: area of Baudó, on the right side of Río Baudó, about 13 km upstream from the estuary of Quebrada Carpio and the shore opposite Quebrada Cola Barquita, 11 Feb. 1967, *Fuchs & Zanella 21294* (MO). EL VALLE: Bajo Calima, ca. 10 km N of Buenaventura, Cartón de Colombia concession, transition between tropical wet and pluvial forest, ca. 50 m, 10 Dec. 1981, *Gentry 35508* (MO).

Cordia gentryi is most easily distinguished by its caudate leaf apex and large, orange-yellow fruits. It most resembles *C. panamensis* and *C. anisophylla* J. S. Miller. *Cordia panamensis* differs in having hirsute twigs and white fruits shorter than 7.5 mm. *Cordia anisophylla* differs in having thinner ellipsoid fruits 6–7.5 mm broad and less-prolonged leaf apices.

NOTES

A NEW *ASPIDOGYNE* (ORCHIDACEAE) FROM VENEZUELAN GUAYANA

The genus *Aspidogyne* Garay is one of the recent segregates from *Erythrodes* Bl. (Garay, 1977) and comprises 27 species, widely distributed in the American tropics, primarily Brazil. They are small to medium-sized terrestrial, humicolous, to (rarely) subepiphytic herbs growing in mostly shady places of rain or cloud forests.

Aspidogyne belongs to the pantropical subtribe *Physurinae*, of seven genera. Among them, *Aspidogyne* can be recognized by the following combination of features: horizontal stigmata; elongate, erect column; and entire emarginate rostellum.

A revision of the *Aspidogyne* species of the Venezuelan Guayana for the orchid treatment in Steyermark's *Flora of the Venezuelan Guayana* has revealed a different identity for the species that appeared in Foldats (1970) as *Erythrodes picta* (Lyndley) Ames, a synonym of *Aspidogyne argentea* (Vell.) Garay. Foldats had already noted that the Venezuelan material cited under *E. picta* differed from the type, and suggested that it might represent a new variety. New evidence shows that the differences are sufficient for recognition of a new species, described below.

Aspidogyne steyermarkii Carnevali & Foldats, sp. nov. TYPE: Venezuela. Bolívar: cabeceras del Río Chicanán, Sierra de Lema, 80 km SW de El Dorado, 500 m, 6°5′N, 62°W, 22 Aug. 1967, *Steyermark 89371* (holotype, VEN; isotype, MO).

Species haec *A. argentea* (Vell.) Garay similis, at sepalo dorsali acuto, petalis non lobulatis, calcari cylindrico, labelli lobo centrali transvere rhombico recedit.

Terrestrial herbs, 9–19 cm high. Stems basally rhizomatose, creeping at the base, aphyllous, apically ascendent to erect, 2–6-foliate. Leaves deep olive-brown with red streaks on both sides of midrib and with the same colored spots near margin above, pale lavender with pale streaks and dots below, ovate to ovate-elliptic, acute, basally rounded to somewhat truncate, 7–28 mm long, 8–12 mm wide; petioles about 12 mm long, basally dilated and sheathing. Inflorescences of erect, laxly pauci- to pluriflorous racemes, 4.5–11 cm long, the peduncle densely pubescent. Flowers resupinate, small, with white tepals and labellum. Tepals uninnervate, subfleshy. Dorsal sepal elliptic, acute, 4 mm long, 1.2 mm wide; lateral sepals ovate-elliptic, subacute, basally attenuate, somewhat oblique, 5 mm long, 2 mm wide; petals narrowly obovate-elliptic, acute, 3.8 mm long, 1.1 mm wide. Labellum elliptic in overall outline, 5.1 mm long, 2.7 mm wide, contracted above its apical third, obovate below the contraction, dilated in a transversely rhombic terminal lobe above, 0.8 mm long, 1.2 mm wide, subacute. Spur cylindric, acute, slightly arched, 5.2 mm long, 0.7 mm thick. Column clavate, 3 mm long; rostellum aristate, acute.

This new species belongs in sect. *Argenteae* Garay. It is similar to *Aspidogyne argentea* (Vell.) Garay but differs by having acute (vs. rounded or obtuse) dorsal sepals, cylindric (vs. fusiform) spur, petals apically not lobulate, and the labellum with a transversely rhombic, subacute (vs. transversely obreniform, truncate, apiculate) apical lobe.

We are grateful to Lic. Bruno Manara for criticism of the Latin diagnosis and for the drawing.

THREE NEW SPECIES OF *BOMAREA* (ALSTROEMERIACEAE) FROM MESOAMERICA

During preparation of the treatment of *Bomarea* Mirbel for the *Flora Mesoamericana*, I found three previously undescribed species in the Missouri Botanical Garden herbarium (MO). The types of all three species are from Panama, from where no new species have been described since the treatment of the genus in the *Flora of Panama* (Killip, 1945).

Characters of these new species common to all Alstroemeriaceae (Dahlgren et al., 1985) are: sepals 3; petals 3; stamens 6 with anthers pseudobasifixed (the tip of the filament inserted in a deep

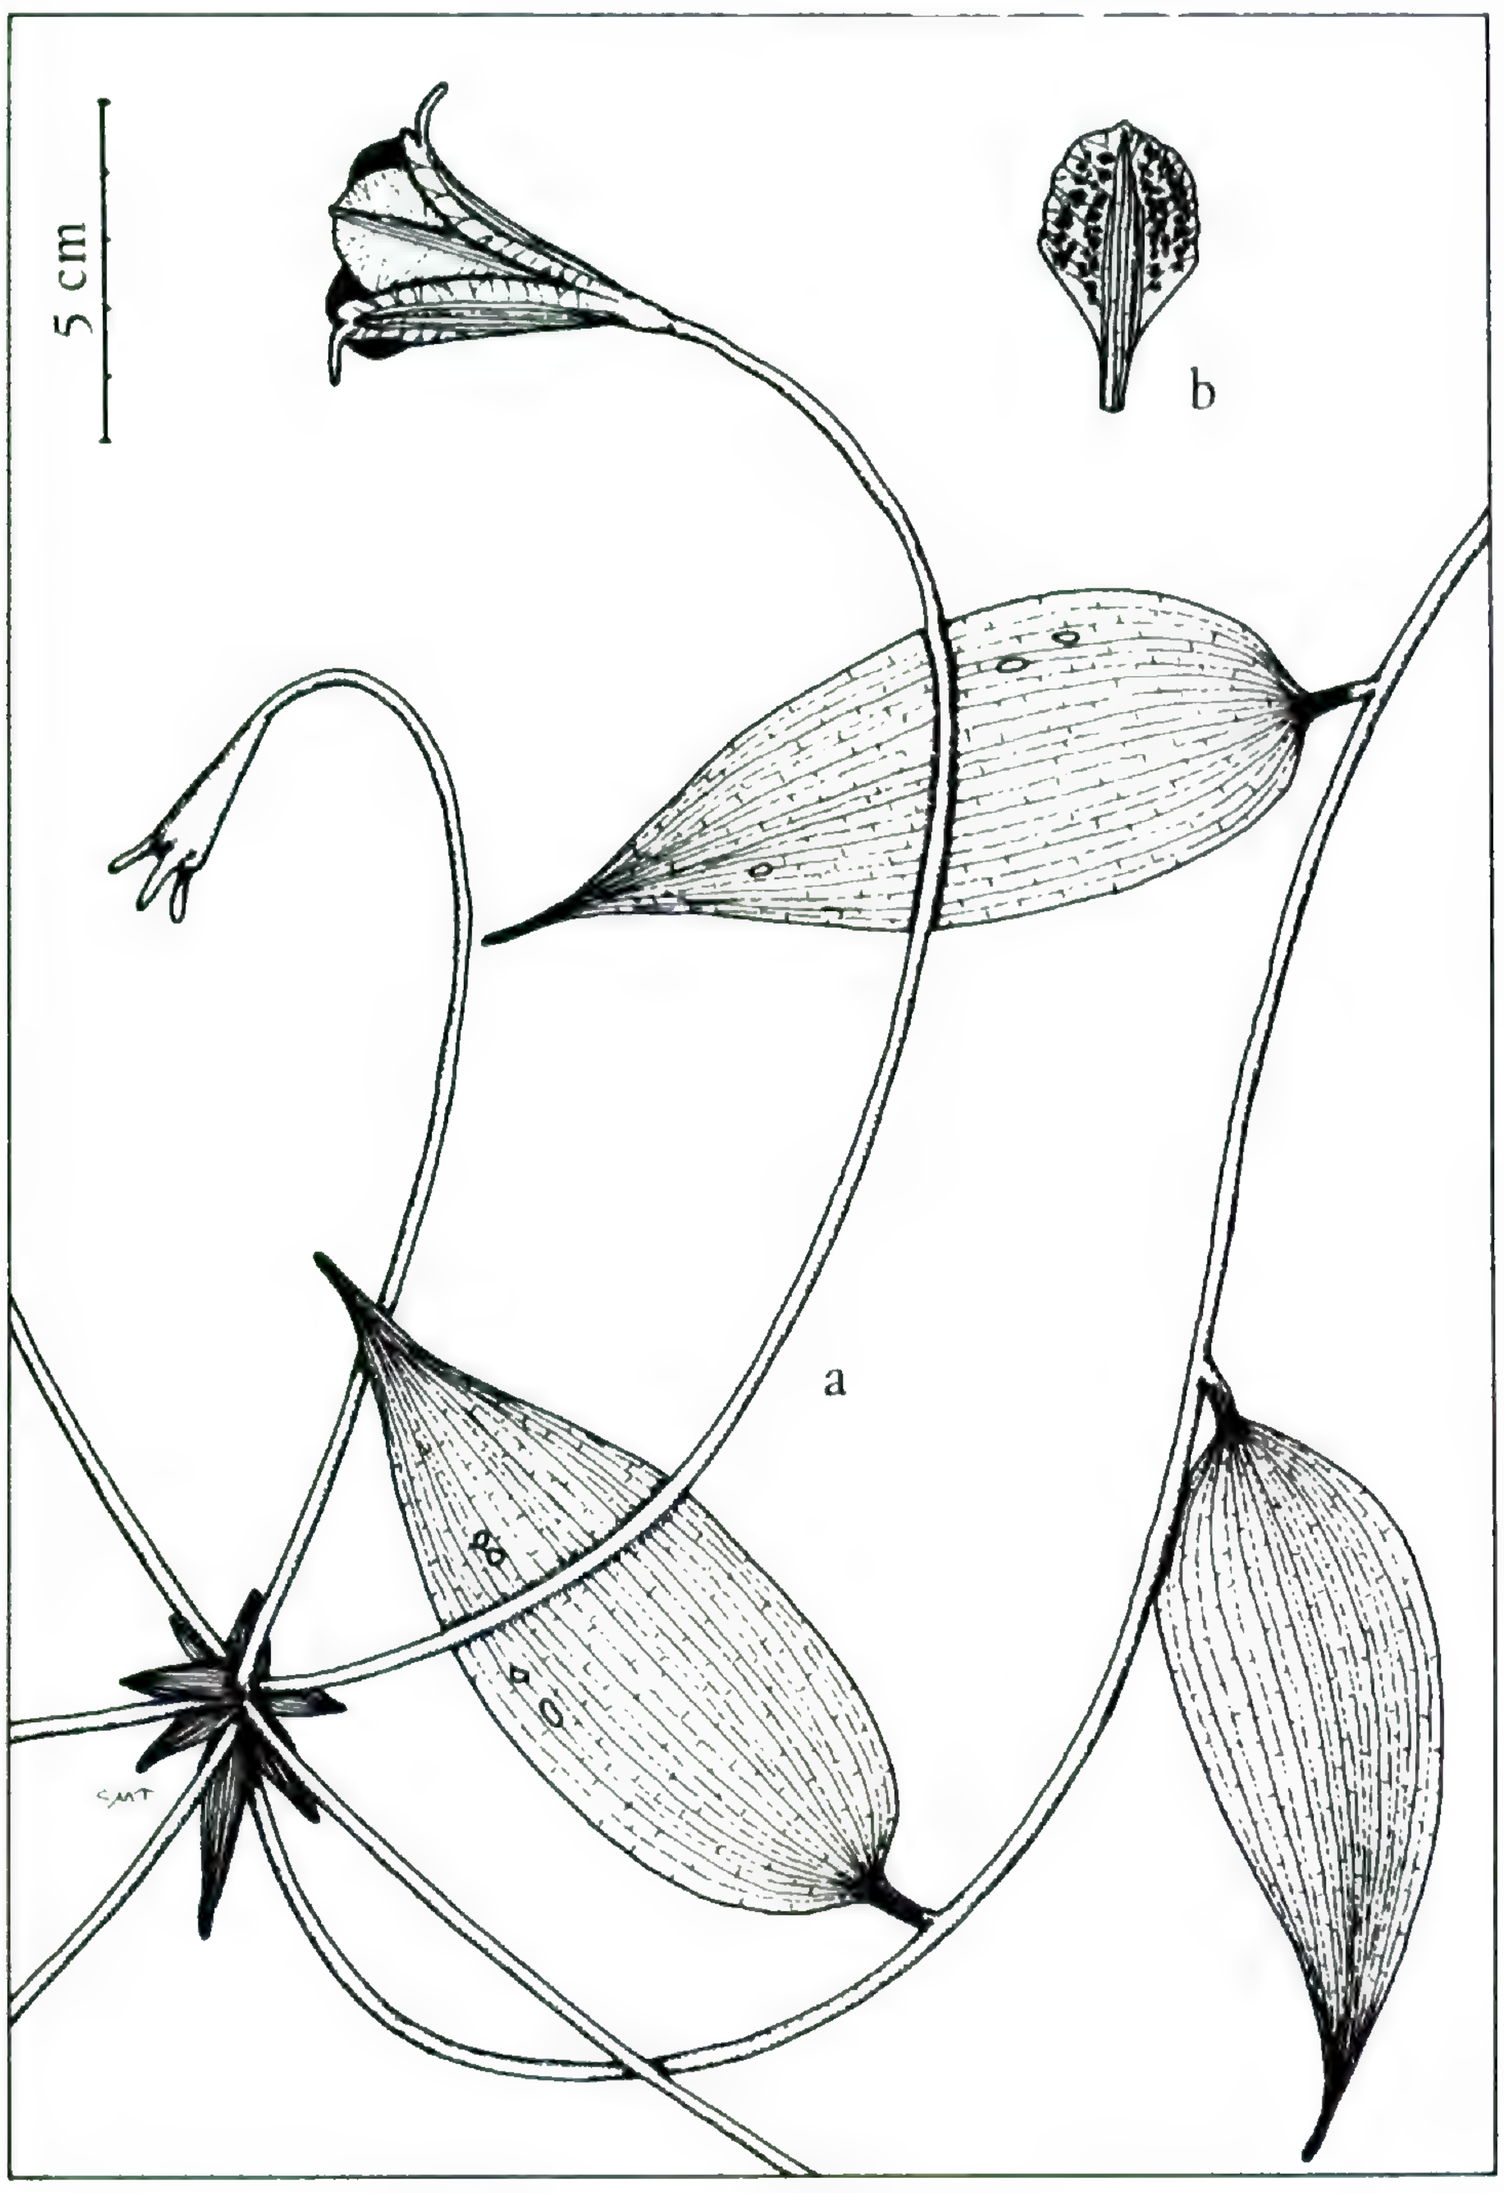

FIGURE 1. *Bomarea caudatisepala.*—a. Plant showing two inflorescence rays.—b. Petal, inside surface (same scale as a). (From holotype, with one leaf from *Sytsma et al. 4871.*)

pit) and introrsely dehiscent; style 1 with 3 stigmatic branches. Like all other Mesoamerican species of *Bomarea*, the new species have fully inferior ovaries and loculicidally dehiscent, capsular fruits. Stem diameter is measured between the first and second leaves below the umbel; length of compound umbel rays is measured from the involucre to base of the uppermost ovary.

Bomarea caudatisepala Gereau, sp. nov. TYPE: Panama. Chiriquí: 8°46′N, 82°25′W, upper NE slopes of Cerro Pate de Macho and along soggy ridge of Continental Divide, 1,900–2,000 m, 19 June 1987, *Croat 66496* (holotype, MO; isotype, PMA). Figure 1.

Herba volubilis caule glabro ad parce puberulo sub umbella. FOLIUM: lamina ovato-lanceolata, 6.9–12.5 cm longa × 2.7–4.5 cm lata, superne glabra, inferne secus nervos glabra ad parce crispato-pubescente. UMBELLA: bracteis involucralibus 5–8, 3.1–3.8 cm longis × 0.4–0.5 cm latis, glabris; radiis 6–14, 17.1–26.2 cm longis, saltem versus apicem parce fulvo-puberulis, simplicibus ebracteolatisque. FLOS: sepalis oblongo-lanceolatis, 3.6–4.0 cm longis × 0.9 cm latis, externe aurantiacis, unoquoque sepalo cornu viridi 7–10 mm longo sub apice 2–4 mm inserto munito; petalis obovatis, 3.8–4.3 cm longis × 1.6–1.7 cm latis, sepala per 2–5 mm excedentibus, externe aurantiacis, interne flavo-aurantiacis ad viridibus, purpureo-maculatis; ovario anguste obconico, sub anthesi 7–10 mm longo × 3–5 mm lato, parce fulvo-puberulo.

Vine; stem 2.0–2.5 mm diam., glabrous throughout to sparsely puberulent just below the umbel. Petiole 10–13 mm long; leaf blade ovate-lanceolate, 6.9–12.5 × 2.7–4.5 cm (L/W ratio = 2.6–3.0), glabrous above, glabrous to sparsely crisp-pubescent on the nerves beneath. Involucral bracts 5–8, 3.1–3.8 × 0.4–0.5 cm, glabrous; rays of the umbel 6–14, 17.1–26.2 cm long, sparsely brown-puberulent at least toward the tip, unbranched and ebracteolate. Sepals oblong-lanceolate, 3.6–4.0 × ca. 0.9 cm, externally orange with a green horn 7–10 mm long inserted 2–4 mm below the tip; petals obovate, 3.8–4.3 × 1.6–1.7 cm, exceeding the sepals by 2–5 mm, orange without, yellowish orange to green with purplish spots within; filaments 2.9–3.0 mm long; anthers 4.0–6.0 × 1.9–2.4 mm; ovary narrowly obconic, 7–10 × 3–5 at anthesis, sparsely brown puberulent; style 10–14 mm long; stigmatic branches 1.4–1.9 mm long.

Known only from three collections on Cerro Pate de Macho, in cloud forest and elfin forest at 1,700–2,100 m elevation.

Additional collections examined. PANAMA. CHIRIQUÍ: Cerro Pate Macho NE of Boquete, S slope along path to Finca Serrano, near the crest at ca. 2,000 m, 26 May 1981, *Andersson & Sytsma 1307* (GB, MO); SE slopes and summit Cerro Pate Macho, trail from Río Palo Alto, 4 km NE of Boquete, 1,700–2,100 m, 26 May 1981, *Sytsma, Knapp & Andersson 4871* (MO).

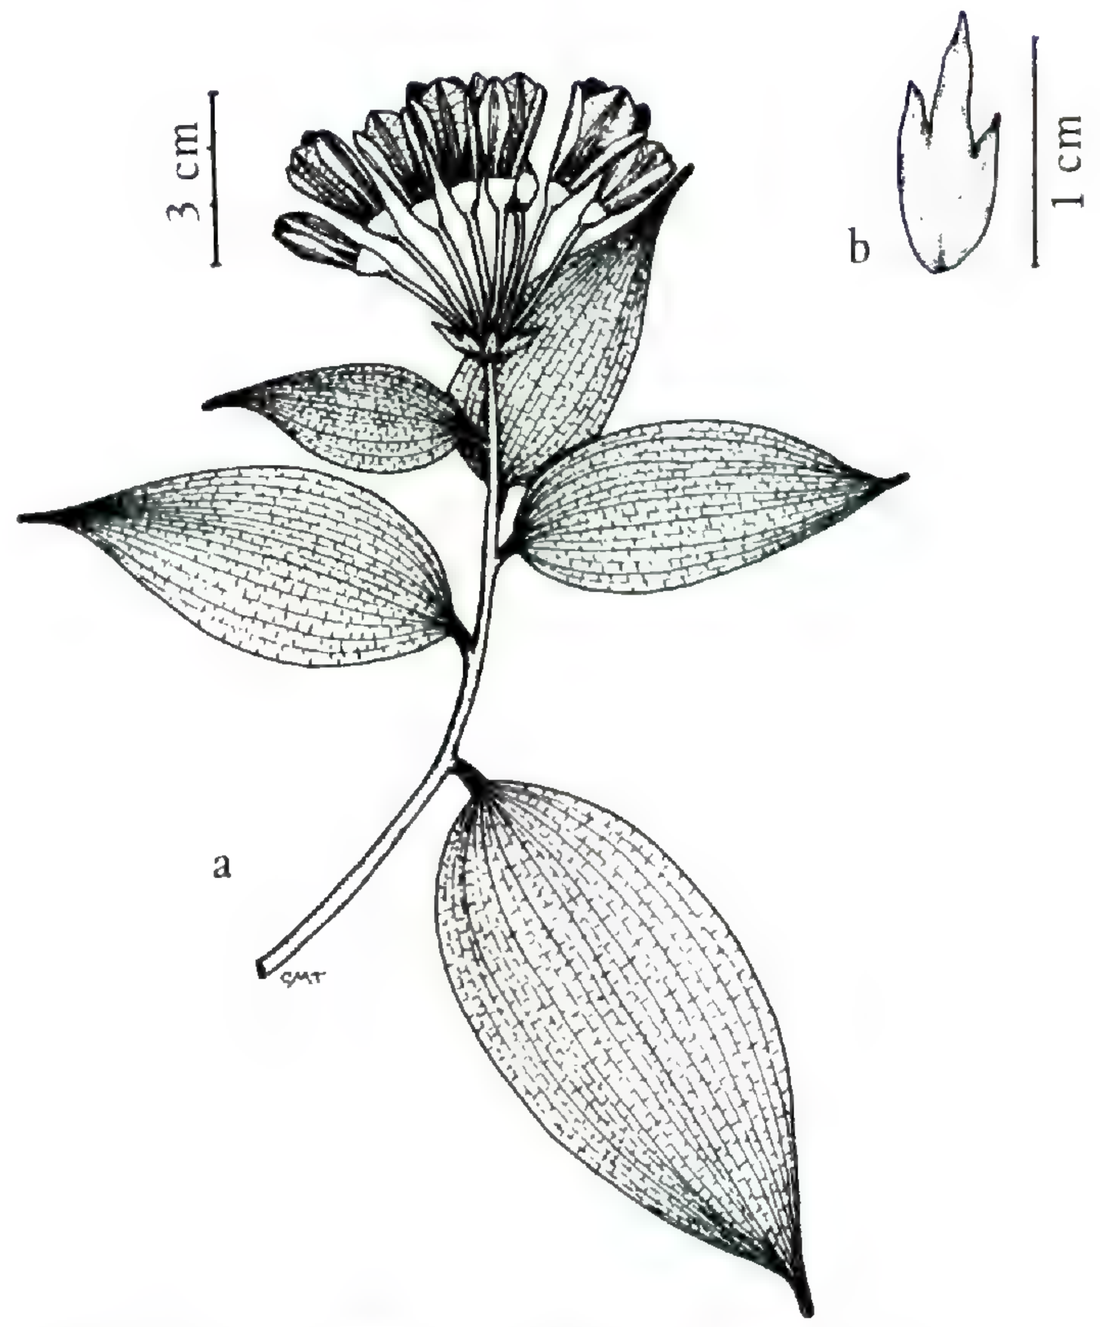

FIGURE 2. *Bomarea suberecta.*—a. Apex of plant with inflorescence.—b. Involucral bract. (From *McPherson 9333*, with one bud from holotype.)

This new species of uncertain affinity is easily distinguished from all other Mesoamerican *Bomarea* by the presence of a horn just below the tip of each sepal. Andean species with horned sepals all have much smaller flowers and further differ from *B. caudatisepala* in having very short umbel rays (*B. caudata* Killip, *B. cornigera* Herbert) or compound inflorescences (*B. cornuta* Herbert).

Bomarea suberecta Gereau, sp. nov. TYPE: Panama. Chiriquí: slope of Cerro Respinga above town of Cerro Punta, 2,500 m, 9 Aug. 1972, *W. G. & J. J. D'Arcy 6587* (holotype, MO). Figure 2.

Herba volubilis vel plerumque suberecta ad erecta, ubi erecta usque ad 2 m alta foliis inferioribus ad squamas reductis; rhizomate radices fibrosas in tumores tuberosos terminantes emittente; caule glabro ad puberulo pilis multicellularibus sub umbella. FOLIUM: lamina late ovata ad ovato-lanceolata, (6.0–)8.2–15.3 cm longa × 3.3–7.2 cm lata, utrinque glabra. UMBELLA: bracteis involucralibus 4–5, 0.9–2.0 cm longis × 0.4–0.6 cm latis, profunde trifidis lobo centrali lateralibus multo longiore, glabris; radiis 5–12, 2.2–4.3 cm longis, dense fulvo-puberulis, simplicibus, ebracteolatis vel (in typo tantum) supra medium bracteolam ca. 5 mm longam gerentibus. FLOS: sepalis oblongo-lanceolatis, 1.7–2.0 cm longis × 0.5–0.7 cm latis, base rubris ad aurantiacis sursum flavescentibus

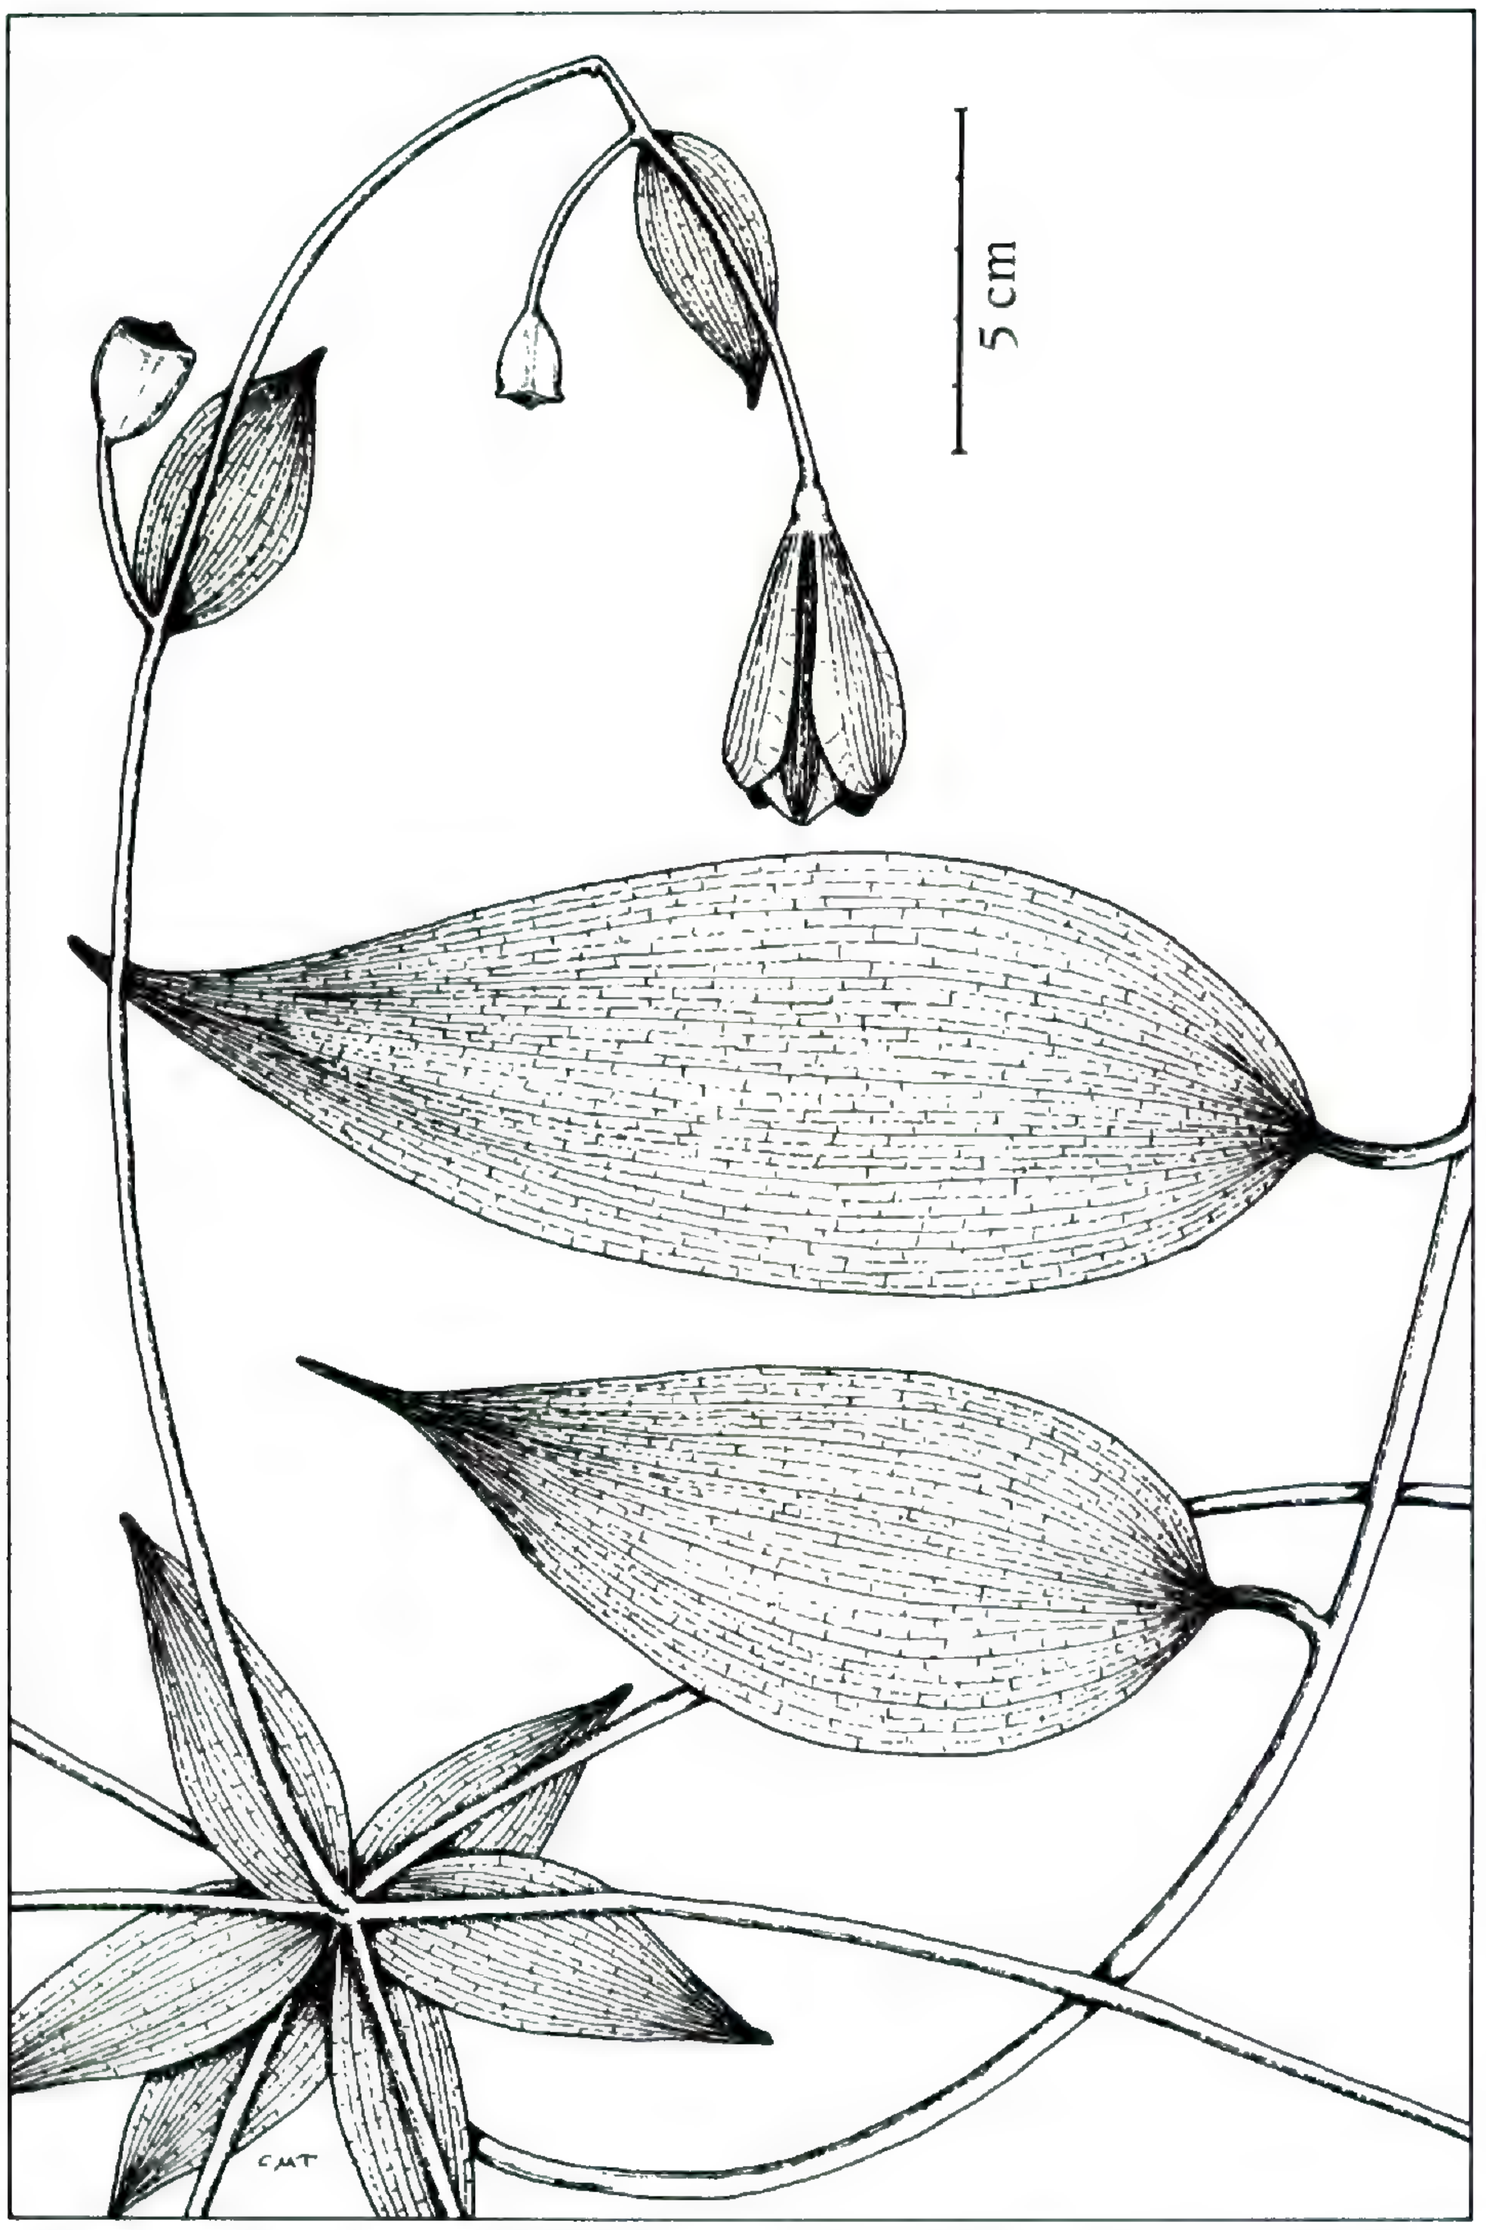

FIGURE 3. *Bomarea bracteolata*. Apex of plant showing one inflorescence ray. (From holotype.)

petalis obovatis, 1.8–2.2 cm longis × 0.7–1.0 cm latis, sepala per 1–3 mm excedentibus, flavis ad aurantiacis; ovario late obovoideo, sub anthesi 4–7 mm longo × 3–5 mm lato, dense fulvo-puberulo.

Vine or more often a suberect to erect herb to 2 m from a creeping rhizome with fibrous roots terminating in tuberous swellings, the lower leaves reduced to scales when plant erect; stem 1.9–4.9 mm diam., glabrous to short-puberulent with multicellular hairs just below the umbel. Petiole 7–16 mm long; leaf blade broadly ovate to ovate-lanceolate, (6.0–)8.2–15.3 × 3.3–7.2 cm (L/W ratio = 1.7–2.7(–3.0)), glabrous above and beneath. Involucral bracts 4–5, 0.9–2.0 × 0.4–0.6 cm, deeply trifid with central lobe much longer than lateral lobes, glabrous; rays of the umbel 5–12, 2.2–4.3 cm long, densely brown puberulent, unbranched, ebracteolate or bearing (only in type) above the middle a bracteole ca. 5 mm long. Sepals oblong-lanceolate, 1.7–2.0 × 0.5–0.7 cm, red to orange at the base, shading to yellow above and green at the tip; petals obovate, 1.8–2.2 × 0.7–1.0 cm, exceeding the sepals by 1–3 mm, yellow to orange; filaments 10–14 mm long; anthers 2.3–3.5 × 1.0–1.6 mm; ovary broadly obovoid, 4–7 × 3–5 mm at anthesis, densely brown puberulent; style 7–15 mm long; stigmatic branches 1.2–3.1 mm long.

Known from the vicinity of Cerro Punta and Cerro Pando (on Costa Rican frontier) in Panama, and from the Atlantic slope of the Cordillera de Talamanca in adjacent Costa Rica, in montane rain forest, *Quercus* forest, and elfin forest at 1,900–2,750 m elevation.

Additional collections examined. PANAMA. CHIRIQUÍ: Cerro Punta, 2,100 m, 3 July 1966, *Blum, Olson & Rasmussen 2428* (MO); Las Nubes, ca. 2,000 m, 7 Aug. 1984, *Croat 26454* (MO), *26472* (MO, PMA); above

Cerro Punta, 2,000 m, 9 May 1971, *D'Arcy 5365* (MO); 8°55′N, 82°44′W, E slopes of Cerro Pando, 2,000–2,300 m, 15 Oct. 1981, *Knapp 1650* (MO); 8°50′N, 82°35′W, road from Cerro Punta village towards Boquete near Bajo Grande, ca. 2,100 m, 5 June 1986, *McPherson 9333* (MO); 8°52′N, 82°33′W, Cerro Punta, along ridge to watershed to Bocas del Toro, 2,200 m, 26 Jan. 1985, *van der Werff & Herrera 6436* (MO, PMA); 8°50′N, 82°44′W, Santa Clara to Cerro Pando, 28 Feb. 1985, *van der Werff & Herrera 7252* (MO, PMA). COSTA RICA. LIMÓN: 9°00′–12′N, 82°57′–59′W, unnamed cordillera between Río Terbi and Río Siní, 2,300–2,500 m, 11 Sep. 1984, *Davidse, Herrera Ch. & Grayum 28957* (MO), 2,400–2,750 m, 13 Sep. 1984, *29046* (CR, MO); 9°14′–15′N, 82°59′W, Kámuk massif, ridge between Río Tararia and NE-most páramo, 1,900–2,300 m, 16 Sep. 1984, *Davidse & Herrera Ch. 29206* (MO).

This new species is distinguished by its deeply trifid involucral bracts; these organs are entire in all other known members of the genus. In Mesoamerica, the new species could only be confused with *B. acutifolia* (Link & Otto) Herbert. In addition to its entire involucral bracts, *B. acutifolia* has larger flowers (petals 2.6–3.9 cm long) than *B. suberecta* and a consistently twining or trailing habit. The suberect to weakly vining habit of *B. suberecta* is otherwise only known in a few Andean species, most notably *B. ovata* (Cav.) Mirbel.

Bomarea bracteolata Gereau, sp. nov. TYPE: Panama. Chiriquí: 8°45′N, 82°15′W, Fortuna Dam, above Gualaca, on forested slopes behind forestry experimental station, ca. 1,200 m, 9 March 1985, *McPherson 6706* (holotype, MO; isotype, PMA, not seen; other isotypes distributed as *B. allenii*). Figure 3.

Herba volubilis caule glabro. FOLIUM: lamina ovato-lanceolata, 13.0–17.5 cm longa × 4.9–6.6 cm lata, superne glabra, inferne secus nervos hyalino-hirsutula pilis multicellularibus complanatis, inter nervos puberula. UMBELLA: bracteis involucralibus 5–10, 4.2–8.8 cm longis × 1.8–3.7 cm latis, superne puberulis; radiis 5–14, 14.9–42.3 cm longis, glabris, bivel trifurcatis, unoquoque ramo bracteola foliacea suffulto, ima 3.6–7.0 cm longa. FLOS: sepalis oblongo-lanceolatis, 4.1–4.8 cm longis × 1.2–1.6 cm latis, rubris vel glauco-salmoneis; petalis anguste obovatis, (3.8–)4.6–5.1 cm longis × (0.8–)1.2–1.3 cm latis, sepalis 3 mm brevioribus ad 3 mm longioribus, externe rubellis, interne pallide viridibus ad flavo-albescentibus, maculis nigris vel atro-purpureis obsitis; ovario obconico, sub anthesi ca. 7 mm longo × 3–4 mm lato, glabro.

Vine; stem 2.3–4.9 mm diam., glabrous. Petiole 16–41 mm long; leaf blade ovate-lanceolate, 13.0–17.5 × 4.9–6.6 cm (L/W ratio = 2.5–2.7), glabrous above, hyaline-hirsutulous with flattened multicellular hairs on the nerves and puberulent between the nerves beneath. Involucral bracts 5–10, 4.2–8.8 × 1.8–3.7 cm, puberulent above; rays of the umbel 5–14, 14.9–42.3 cm long, glabrous, 2- or 3-branched, each branch subtended by a leaflike bracteole, the lowest bracteole 3.6–7.0 cm long. Sepals oblong-lanceolate, 4.1–4.8 × 1.2–1.6 cm, red or glacous pink-salmon; petals narrowly obovate, (3.8–)4.6–5.1 × (0.8–)1.2–1.3 cm, from 3 mm shorter to 3 mm longer than the sepals, reddish without, pale green or yellow-white with black or dark purple spots within; filaments ca. 36 mm long; anthers ca. 5.6 × 2.1 mm; ovary obconic, ca. 7 × 3–4 mm at anthesis, glabrous; style ca. 36 mm long; stigmatic branches ca. 2.7 mm long.

Known from the provinces of Chiriquí and Veraguas in Panama, in premontane wet forest at 750–1,350 m elevation.

Additional collections examined. PANAMA. CHIRIQUÍ: type locality, 9 Mar. 1985, *McPherson 6704* (MO, PMA); 8°45′N, 82°15′W, Fortuna Dam, in valley S of lake, 1,200–1,300 m, 25 Dec. 1986, *McPherson & Aranda 10126* (MO, PMA). VERAGUAS: vicinity of Santa Fé, slopes of Cerro Tute, 750 m, 25 Mar. 1947, *Allen 4367* (MO); Cerro Tute, trail past agricultural school near Santa Fé, 1,200 m, 17 Sep. 1979, *Antonio 1853* (MO); 8°32′N, 81°07′W, trail to Cerro Tute, above Escuela Agrícola Alto de Piedra just W of Santa Fé, 800–1,350 m, 5 June 1982, *Knapp & Dressler 5456* (MO).

Bomarea bracteolata is probably most closely related to *B. allenii* Killip, the only other large-flowered Mesoamerican *Bomarea* with branched umbel rays. These species differ in sepal length (4.1–4.8 cm in *B. bracteolata*, 5.3–6.5 cm in *B. allenii*), lower leaf surface (pubescent in *B. bracteolata*, glabrous in *B. allenii*), and length/width ratio of leaf blades (2.5–2.7 in *B. bracteolata*, 4.0–5.4 in *B. allenii*). The inflorescence and flowers of *B. bracteolata* are very similar to those of *B. kranzlinii* Baker of Colombia (cf. *Stein & McDade 3205*, MO), but the latter species has smaller bracts and bracteoles and narrower leaves that are glabrous beneath.

HOSTA YINGERI (LILIACEAE/FUNKIACEAE): A NEW SPECIES FROM KOREA

The genus *Hosta* Tratt. includes ca. 22–25 species of rhizomatous herbaceous perennials from Japan, China, and Korea. The genus is well known to gardeners in the United States, Europe, and New Zealand, since the species and cultivars are widely grown in shady gardens for their attractive foliage and flowers (Aden, 1988). They are also grown as ornamentals and eaten cooked in China, Japan, and Korea. Traditionally *Hosta* has been placed in the Liliaceae (e.g., Cronquist, 1981) or in the Funkiaceae (Dahlgren et al., 1985) along with *Hesperocallis* A. Gray and *Leucocrinum* Nutt. ex A. Gray, both from western North America.

Bailey (1930) and Stearn (1931) noted that *Hosta* is a taxonomically difficult genus with confused nomenclature. Although a number of papers have been published on *Hosta* during the past 50 years, there has been little improvement in our understanding of the genus. The matter has been largely complicated by broad (Fujita, 1976) or narrow (Maekawa, 1940) species concepts and confusion caused by cultivars. The plants have relatively few good diagnostic features that can be observed in pressed and dried herbarium specimens (Hylander, 1954). In an attempt to improve our knowledge of *Hosta*, my associates Carleen Jones, Myong Chung, and Haynes Currie and I have been attempting to assemble a collection of living hostas. Several years ago Barry R. Yinger, then of the U.S. National Arboretum, supplied seeds of several accessions of *Hosta* collected from Taehuksan Island, a remote island off the southwestern coast of Korea. Examination of my cultivated plants and field-collected vouchers at NA reveals a new species, named in honor of the collector, Barry Yinger.

Hosta yingeri S. B. Jones, sp. nov. TYPE: Korea. Cholla Namdo, Shin An Gun, Huksan Myon, Taehuksan Island, east side of Yeri village, 34.40N, 125.6E. Among rocks on northwest-facing talus slope, shade, on cut-over hillside, ca. 60 m, common, 23 Sep. 1985, *B. R. Yinger, T. R. Dudley, J. C. Raulston, A. P. Wharton & Y. J. Chang 3616* (holotype, NA). Figure 1.

Lamina folii elliptica-lanceolata vel anguste-ovata, semierecta; apex acuminatus, petiolus valde sulcatus, basis laminae paullatim in petiolum attenuata; petiolus superne alatus et inferne paullatim angustatus; scapus viridis glaber levis, racemo laxo multifloro terminatus, bracteis parvis instructus; flores non-secundi, perianthium sex-partitum, tubiforme-infundibuliforme; stamina tria + tria, libera, exserta, declinata, in base perianthii affixa; tria filamenta elongata.

Plants glabrous, herbaceous perennials from short, clumpy rhizomes. Leaves ascending obliquely, spirally arranged at base of stem; petioles 3–7(–15) cm long, 2–5 mm wide at the middle of the petiole, greenish or sometimes with purple spots, winged; blades 4–15(–21) cm long, 2.2–7(–11) cm wide, elliptic-lanceolate or narrowly ovate, rigid and heavy-textured, acuminate at the apex, gradually narrowed at the base into the petiole, having a V-type fold in the base of the blade extending down into the petiole, the veins of upper leaf surface inconspicous when fresh, the veins of lower leaf surface in 3–4(–6) pairs of prominent, smooth lateral veins on either side of the midrib. Scapes 2–4 times longer than the leaves, erect, smooth, usually with 1–2 linear-lanceolate bracts below the inflorescence, 1–2 cm long, 2–3 mm wide; raceme 20–25-flowered, the flowers equally arranged around the central axis of the raceme; pedicels 1.2–2 cm long, longer than the subtending bracts; bracts flat, greenish, papillose at the apex, 8–12 mm long, 2–3 mm wide. Perianth (fresh) whitish purple, tubular-funnelform, ca. 3.6–4 cm long; tube slender, ca. 1.8–2 cm long, ca. 5 mm wide, white inside; throat white with purple between each lobe, veins not intensely colored; limb ca. 1.8–2 cm long, lobes 6, ca. 5 mm wide, inner surface light purple; tops of the flower buds purplish. Stamens distinct, 3 + 3, conspicuously exserted; filaments white, attached to the base of the perianth tube, strongly declined, then curving upwards, one set ca. 3.1 cm long, the other ca. 4.4 cm long, the filaments attached to the connective of the anthers in a groovelike pit; the anthers ca. 3 mm long, white beneath, black above. Style filiform, ca. 4.5 cm long, exserted beyond the stamens; stigma small, capitate, moist. Capsules cylindric,

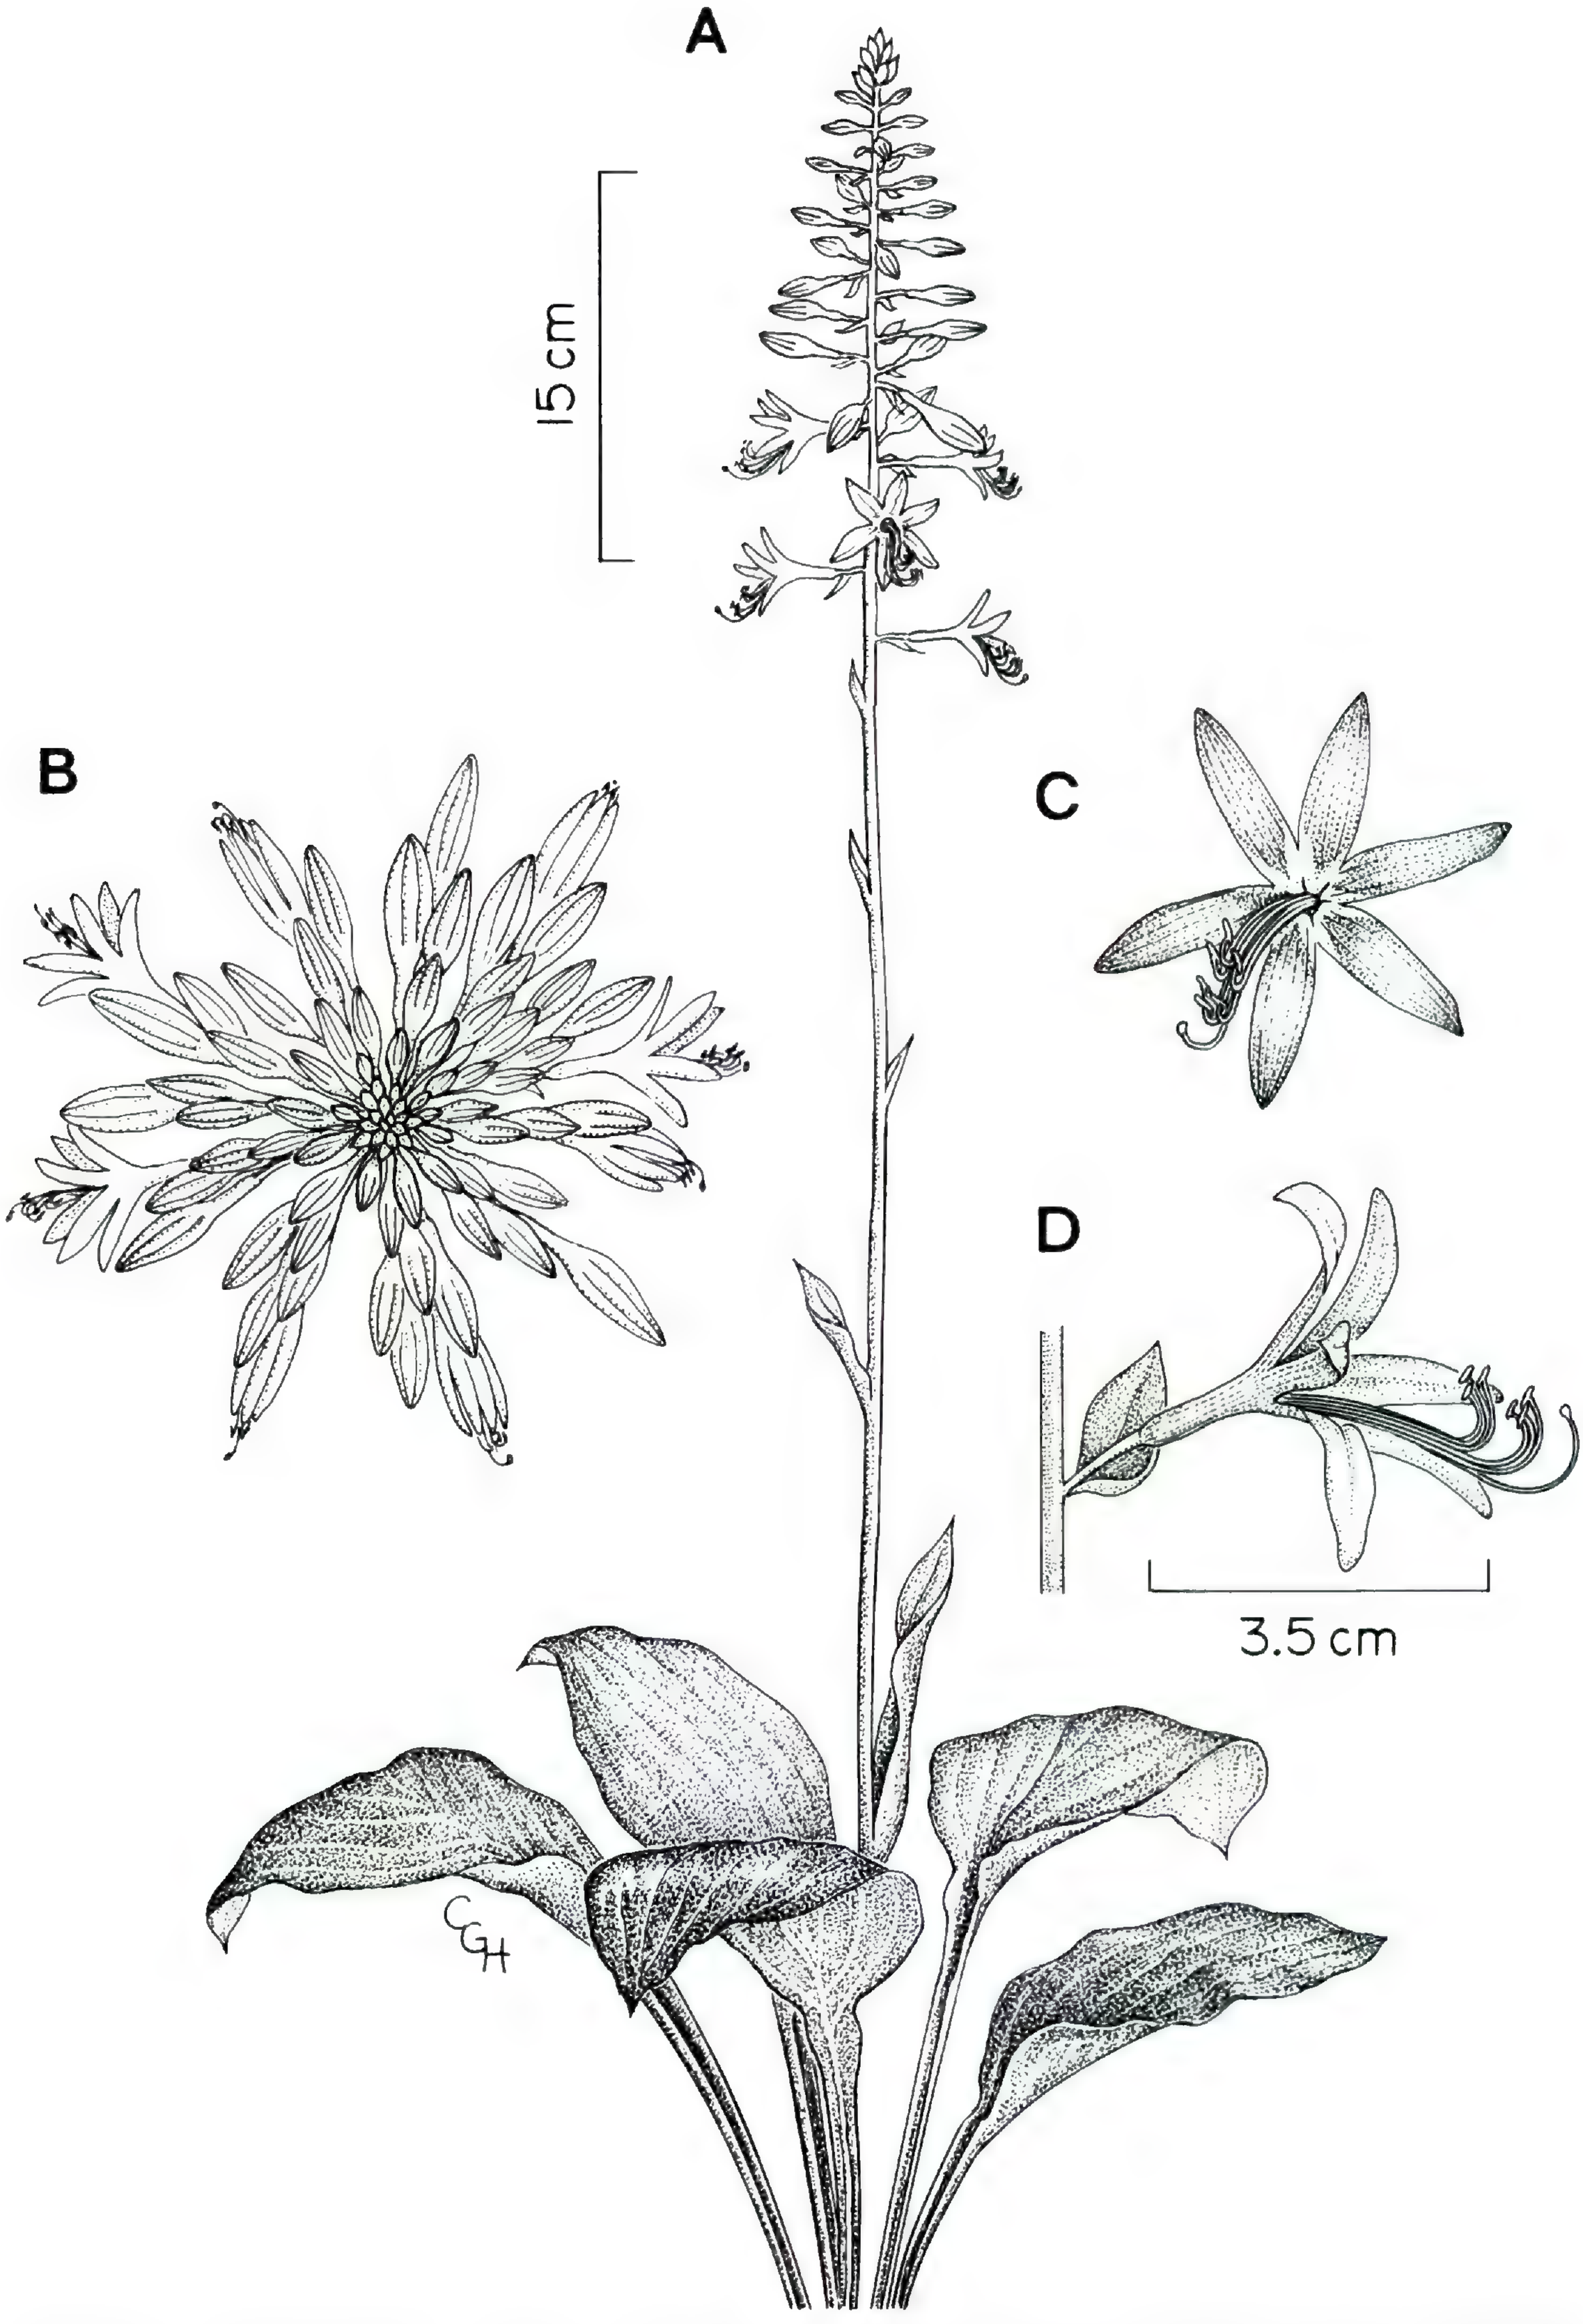

FIGURE 1. *Hosta yingeri.*—A. Habit.—B. Downward view of the raceme axis showing the flowers spread evenly around the central axis of the inflorescence.—C. Flower viewed from front.—D. Flower viewed from the side. (Drawing prepared by Carol L. Gubbins Hahn from fresh material of garden-grown seedlings of holotype collection.)

2.5–3 cm long, 4.5–6 mm wide; seeds black, flattened, winged, ca. 8.4 mm long, ca. 3.4 mm wide; cotyledon small, undifferentiated.

Flowering in August and September in Korea and in my garden located in northeast Georgia in August; fruiting and maturing seed in September and October.

Paratypes. KOREA. TAEHUKSAN ISLAND: garden-grown material of same collection as holotype, *Yinger et al.* (GA); *Yinger et al. 3585* (NA) and garden-grown material (GA); *Yinger et al. 3244, 3610* (NA) and garden-grown material (GA); Sohuksan Island, *Yinger et al. 3164* (NA).

Hosta yingeri is distinct from other species of *Hosta* in its relatively thick, adaxially dark green leaves. This feature may be an adaptation to its coastal habitat, growing at 2–60 m above sea level. It is also distinguished by its delicate raceme of flowers spread evenly around the central axis of the inflorescence; typically, *Hosta* has subsecund racemes. An additional diagnostic feature of *H. yingeri* is the exceptional length of the second set of stamens, with both sets exserted well beyond the perianth. Our living material has been compared with representative accessions of all species of *Hosta* in our garden and with loans of herbarium material. *Hosta yingeri* is an attractive and interesting new species with horticultural potential. It appears to be associated with Maekawa's (1940) subgenus *Bryocles*, section *Tardanthae*. *Hosta yingeri* does not resemble our garden-grown material of *H. tsushimensis* obtained from the National Arboretum.

LINDSAEA MESARUM, A NEW FERN SPECIES FROM THE RORAIMA SANDSTONE

When the present author published his revision of the New World species of *Lindsaea* (Kramer, 1957), the collection *Tate 430* (NY) was cited as a probably distinct but as yet insufficiently known, undescribed taxon. This taxon is now known by over 20 collections and is therefore described as new.

Lindsaea mesarum Kramer, sp. nov. TYPE: Venezuela. Bolívar: Distr. Piar, summit of Murisipán-tepuí, Aparamá Range, 5°53′N, 62°03′W, sandstone mesa, cracks of rock, 2,200 m *B. K. Holst 3548* (holotype, MO; isotype, Z). Figure 1.

Rhizoma breviter repens, squamis parvis, fuscis vestitum. Folia approximata; petiolus obscurus, abaxialiter rotundatus vel superne applanatus. Lamina bipinnata, pinnis primariis paucis, usque ad 3 pro latere et terminali conformi; rhachis primaria abaxialiter biangularis vel sulcata, secundariae subacute biangulares. Pinnulae numerosae, coriaceae, in sicco obscurae, semi-ovatae vel subtriangulares, margine anteriori recto, plerumque inciso, incisionibus paucis, haud profundis, inconspicuis sed pro lamina omni numquam carentibus. Venae immersae, simplices vel unifurcatae, liberae. Sori interrupti incisionibus marginis, vel continui ad pinnulas minores; indusium firmum, marginem subaequans. Sporae triletae.

Rhizome rather short-creeping, 1.5–2.5 mm diam.; scales fuscous, small, narrowly triangular with broad base, acuminate, ca. 1 × 0.2 mm, ca. 8-seriate at base. Leaves a few–several mm apart; petiole usually lustrous, atropurpureous to black, smooth but the basal part bearing some small wart-like bases of shed scales: adaxial (sometimes also abaxial) side flattened (near the apex) to faintly sulcate, abaxial side otherwise rounded; length ca. 12–22 cm, equaling the lamina to much exceeding it. Lamina narrowly oblong, ca. 10–20 cm long, paucijugate-bipinnate, or a few once-pinnate or subbipinnate sterile leaves present beside the bipinnate fertile ones; primary rachis dark reddish to blackish brown, abaxially faintly biangular to distinctly sulcate. Pinnae from 1 odd one to more often 1–3 pairs and a conform terminal one, moderately to very strongly ascending, hence the width of the lamina quite variable; lateral pinnae with a petiolule of ca. 8 mm, 7–10(–16) cm long, up to 15 mm wide, somewhat narrowed near the base, gradually and strongly tapering to the apex. Secondary rachises medium to dark brown, dull, adaxially sulcate, the groove bordered by rounded ridges, abaxially subacutely biangular. Pinnules close to contiguous or even overlapping, coriaceous, often blackish when dry, dull or adaxially sublustrous, dimidiate, spreading or somewhat ascending, up to ca. 25 well-developed ones to a side, above these some much-reduced pinnules, a few finally confluent into a short, pinnatifid pinna-apex. Larger pinnules ca. 6–9 mm long, 3.5–5 mm wide, about 1.5 times as long as wide, semiovate to subtriangular, base cuneate, posterior margin straight or convex, anterior margin approximately straight, entire or more often distantly and shallowly incised to ca. 0.5 mm, the lobes flanking the incisions mostly touching to overlapping, thus the incisions inconspicuous. Inner margin of pinnules straight, diverging from the rachidule, an outer margin not developed; all margins, especially the posterior, sclerotic, apex subacute to obtuse but not rounded. Sterile pinnules very shallowly and rather irregularly crenate. Veins immersed but somewhat evident, adaxially often slightly impressed in dry specimens, free, simple or the inner forked above the base, ca. 5–8 vein-ends per pinnule present. Sori occupying the anterior margin, interrupted, or in small pinnules continuous, (1–)2–5 per pinnule, each on 1–4(–6) vein-ends, ca. 1.5–4 mm long; indusium firm, entire, often somewhat undulate (not sinuate!), about equaling the margin, ca. 0.4 mm wide. Spores trilete, subtetrahedral, tawny, smooth, with prominent laesura, ca. 35 μm (proximal) × 26 μm (lateral view).

Paratypes. VENEZUELA. BOLÍVAR: Distr. Piar, Aparamá Range, Camarcaibaraí-tepuí, 2,400 m, shaded ledge, *B. K. Holst 3632* (MO, Z); Murisipán-tepuí, 2,350 m, eroded sandstone mesa, *Holst, Steyermark & Liesner 2947* (MO, Z); summit of Auyan-tepuí, 2,140 m, sandy ground under large rock, *Steyermark, Carreño E., McDiarmid & Brewer-Carías 116035* (UC); Chimantá Massif, Apacará-tepuí, ca. 2,200 m, *Steyermark, Huber & Carreño E. 128445* (MO, UC). AMAZONAS: Dept. Atabapo, Cerro de Marahuaco above Salto Los Monos, 2,255 m, base of rock, *Liesner 17973* (MO), *18003* (MO, Z); same locality, 2,520–2,650 m, *Steyermark & Holst*

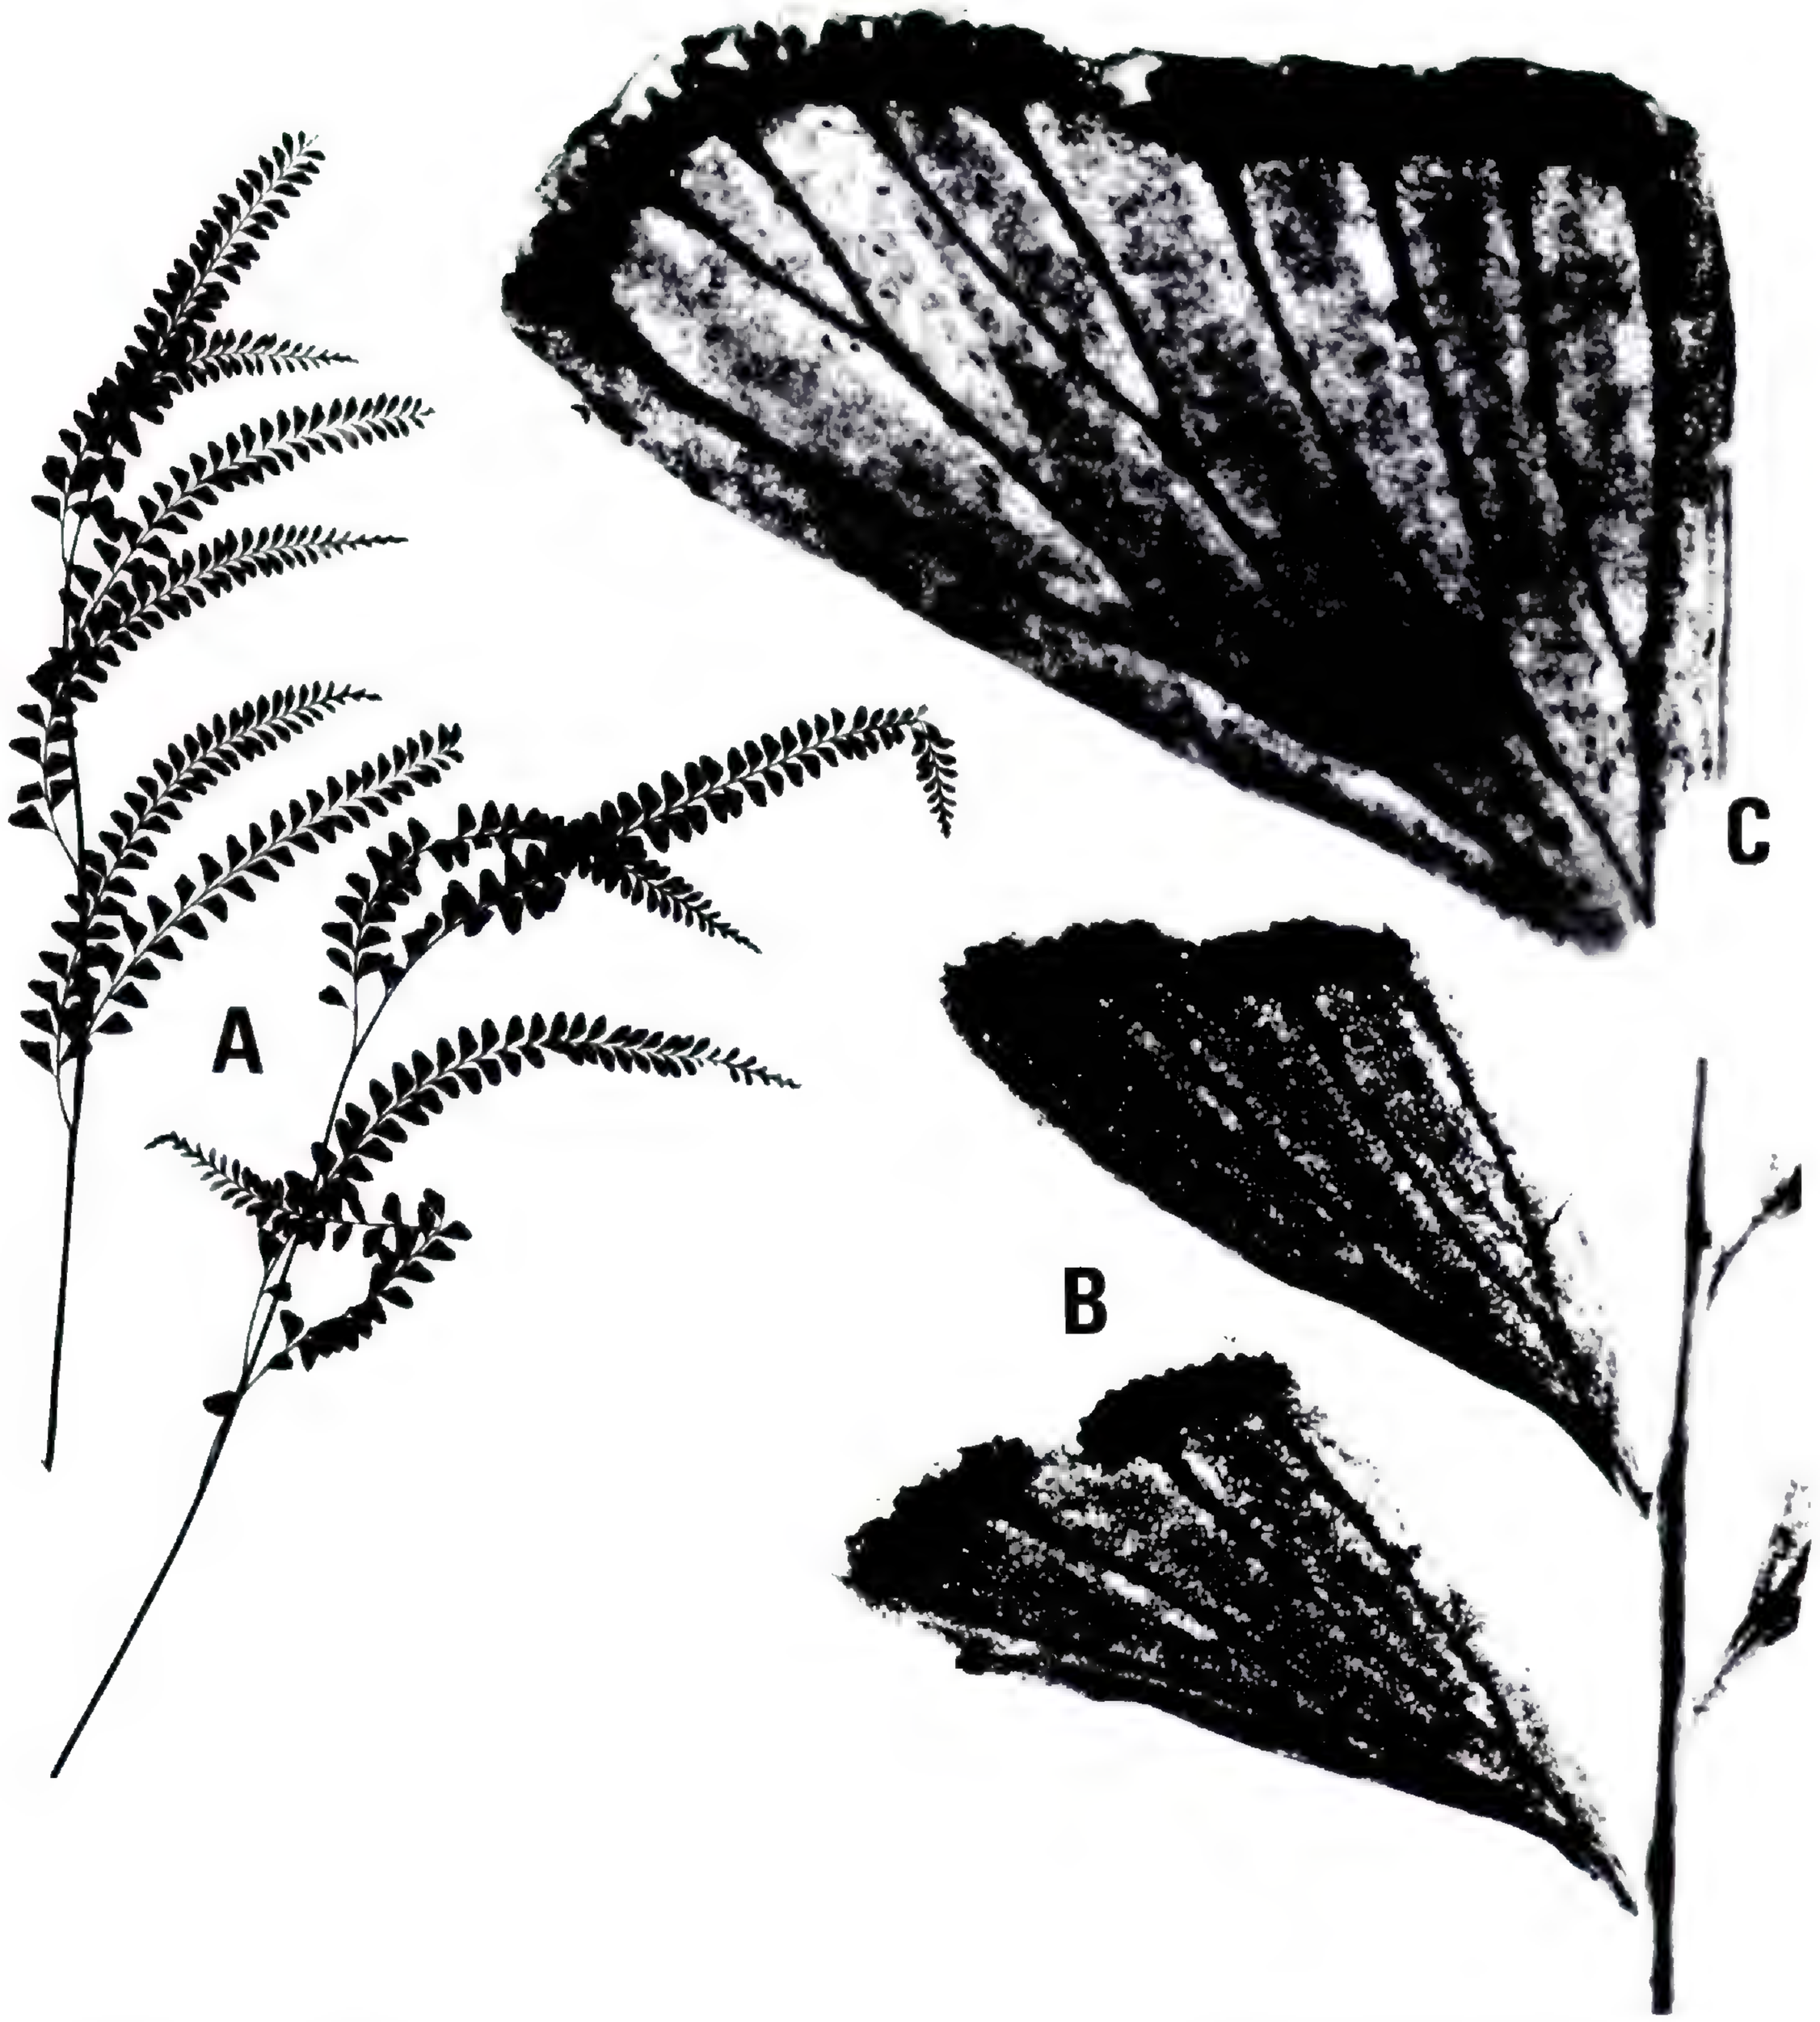

FIGURE 1. *Lindsaea mesarum*—A. Two laminas, × ½.—B. Part of secondary rachis with two pinnules, ×13. —C. A single pinnule, ×20. All from *Holst, Steyermark & Liesner 2947* (Z).

130808 (MO, Z); same locality, 2,580–2,600 m, *Steyermark & Delascio 129253* (UC); same locality, summit, 2,800 m, *Steyermark & Delascio 129096* (MO); same locality, *Steyermark & Delascio 129214* (NY); Cerro Marahuaca-Fhuif, summit, 2,480–2,500 m, *Steyermark, Guariglia, Holmgren, Luteyn & Mori 126072, 125979* (NY); same locality, 2,580 m, same collectors *125947* (NY); Cerro Marahuaca-Shiho, summit, 2,450–2,480 m, same collectors *126351* (NY); same locality, 2,480 m, same collectors *126289* (NY); same locality, 2,450 m, same collectors *126351* (NY); Cerro Duida, Ridge 25, *Tate 430* (NY); Cerro de la Neblina, 3 km ENE of Pico Zoloaga, 1,900–2,000 m, *Stein & Gentry 1606* (MO); same locality, S slopes of Cañon Grande, 1,770–1,850 m, *Croat 59509* (MO); Dept. Río Negro, Cerro de la Neblina, ridge on Venezuela–Brazil border, 2,000 m, *W. W. Thomas & Plowman 3073* (MO, NY, UC).

The following, almost sterile collection may also belong to this species: Cerro de la Neblina, *Liesner 16023* (MO, UC).

All collections are from cracks and crevices of sandstone rocks, from sandy soil in open thickets or other vegetation, or from open forest with *Bonnetia roraimae* (where recorded), between ca.

1,800 and 2,800 m. The species is often described as being locally common.

The interrupted sori were at first taken for an abnormality due to incomplete fertility of the leaves, as is often seen in the genus. The constancy of the character, however, leaves no doubt about its being a distinctive feature of the species.

Lindsaea mesarum resembles *L. stricta* (Sw.) Dryander var. *jamesoniiformis* Kramer in habit, but this is certainly due to convergence. The two taxa occur in the same habitat and are sometimes collected next to each other. The closest relative of *L. mesarum* is *L. klotzschiana* Moritz ex Ettingsh., which has thinner, much more pronouncedly incised pinnules and larger rhizome scales. Another probable relative is *L. parkeri* (Hooker) Kuhn subsp. *steyermarkiana* Kramer, a little-known taxon of somewhat uncertain status; it has thinner pinnules that are much less narrowed towards the apex. If the inconspicuous incisions of the anterior margin of the pinnules of *L. mesarum* are overlooked, it will key out to *L. stricta* (Sw.) Dryander in the present author's key (Kramer, 1957); from this it can be distinguished by its smaller rhizome scales, and the forms of *L. stricta* with dark leaf axes have strongly rounded pinnules.

The author is indebted to the Curators of the Herbaria MO, NY, and UC for lending and/or donating material, and to Mr. A. Zuppiger, Zürich, for preparing the illustration.

TWO NEW SPECIES OF *PASSIFLORA* SECTION *DECALOBA* (PASSIFLORACEAE) FROM COSTA RICA

Living collections of two species of *Passiflora* L. section *Decaloba* DC. were made in Costa Rica and subsequently studied in cultivation. Both were found to represent undescribed species. The study of the living plants as well as herbarium specimens has allowed the following detailed descriptions. Color names follow the standardized English names system of the ISCC-NBS (1965).

Passiflora nubicola MacDougal, sp. nov. TYPE: cultivated at Duke University, 1980, from stem of *MacDougal 220* collected 27 Aug. 1977 in: Costa Rica. Puntarenas: Cordillera de Tilarán, road through Monteverde Cloud Forest Reserve, Pacific slope just below continental divide, ca. 1,540 m, *MacDougal 220GR* (holotype, DUKE; isotypes, BM, CR, MEXU, MO). Figure 1.

Passiflora scandens; petioli eglandulosi; folia bilobata vel trilobata, lobis obtusis vel truncatis, angulo inter lobos laterales 70–90(–100)°, lobis lateralibus quam centrali subaequalibus vel longioribus, marginibus integris; bracteae ad 1.4 mm longae; flores parvi albidi subpendentes; coronae filamenta uniseriata vel biseriata, filamentis exterioribus luteolis 2–3 mm longis; operculum plicatum; ovarium glabrum; semina 8–10 sulcata.

Gracile climbing perennial herb 1.5–3(–4) m long, lightly and minutely puberulent throughout at shoot tip (except laminas) with antrorsely appressed trichomes 0.04–0.10 mm long, becoming very sparsely puberulent or glabrescent on mature structures. Stem 1.5–3 mm diam., perennial with little secondary growth (several-year-old stems 3 mm diam., dark green, not woody), obtusely sub-5-angulate (drying acutely sulcate-striate) and 5–6-carinate, the carinae becoming verrucose and somewhat scabrous below; posture of shoot tip cernuous; phyllotaxy 2/5. Stipules 1–2(–2.5) × 0.15–0.25 mm, linear-triangular, falcate at base, necrescent. Petioles 0.8–2(–2.8) cm, eglandular. Laminas 2.2–4(–4.6) × 4–6(–9.2) cm at fertile nodes, depressed-obovate to strongly depressed-obovate or semicircular in general outline, adaxially glabrous, often with slight variegation consisting of a few discontinuous patches of white between (not along) the primary and secondary veins, abaxially very sparsely puberulent with trichomes restricted to primary and secondary veins, sometimes flushed purplish (especially new growth), margins entire, sparsely puberulent to nearly glabrous, shallowly (2–)3-lobed less than 0.15 the distance to the obtuse base, the lateral lobes obtuse to rounded or truncate, the central lobe (obsolete to) obtuse or truncate and sometimes emarginate, the angle between the primary lateral veins 70–90(–100)°, the ratio of lateral to central vein lengths 1.0–1.4, the ratio of laminar width to length 1.5–2.1; laminar nectaries 8–14(–18) per leaf (to 26 on immature plants), borne abaxially between the primary veins, often appearing light yellowish adaxially, the most proximal pair only occasionally strictly axillary but not enlarged; leaves of juvenile plants similar, variegated, vein ratio close to 1.0; seedlings unknown. Tendrils straight during development at shoot apex. Prophyll of vegetative ramifying bud 1, lanceolate, acuminate. Peduncles 1.0–2.0 cm, geminate, uniflorous; bracts 3, 0.7–1.4 × 0.05–0.25 mm, usually borne near apex of peduncle, linear-triangular, often involute near base and appearing narrowly lanceolate, early necrescent, stramineous. Flowers ca. 1.7–2 cm diam., subpendent, whitish with green and yellow corona, slightly sweetly odorous; floral stipe (3.0–)4–6.0 mm (to 5–9 mm in fruit); hypanthium 5–5.5 mm diam.; sepals 7.5–11 × 2.6–4.4 mm, oblong to oblong-lanceolate, rounded, ecorniculate, pale yellow-green abaxially, whitish adaxially; petals 5.0–7.5 × 2.4–3.4 mm, oblong to ovate-oblong, rounded, white; filamentous corona in 1–2 series, the outer filaments ca. 23–25, 2–3 mm, simply curved and spreading, thickest near the base, abaxially flattened, slightly laterally compressed, the apex obtuse or rounded, light yellowish green basally, bright yellow toward apex; inner series (if present) 1.8–2.2 mm, capillary, clavate or dilated at the apex, inclined toward androgynophore; operculum 0.9–1.5 mm, membra-

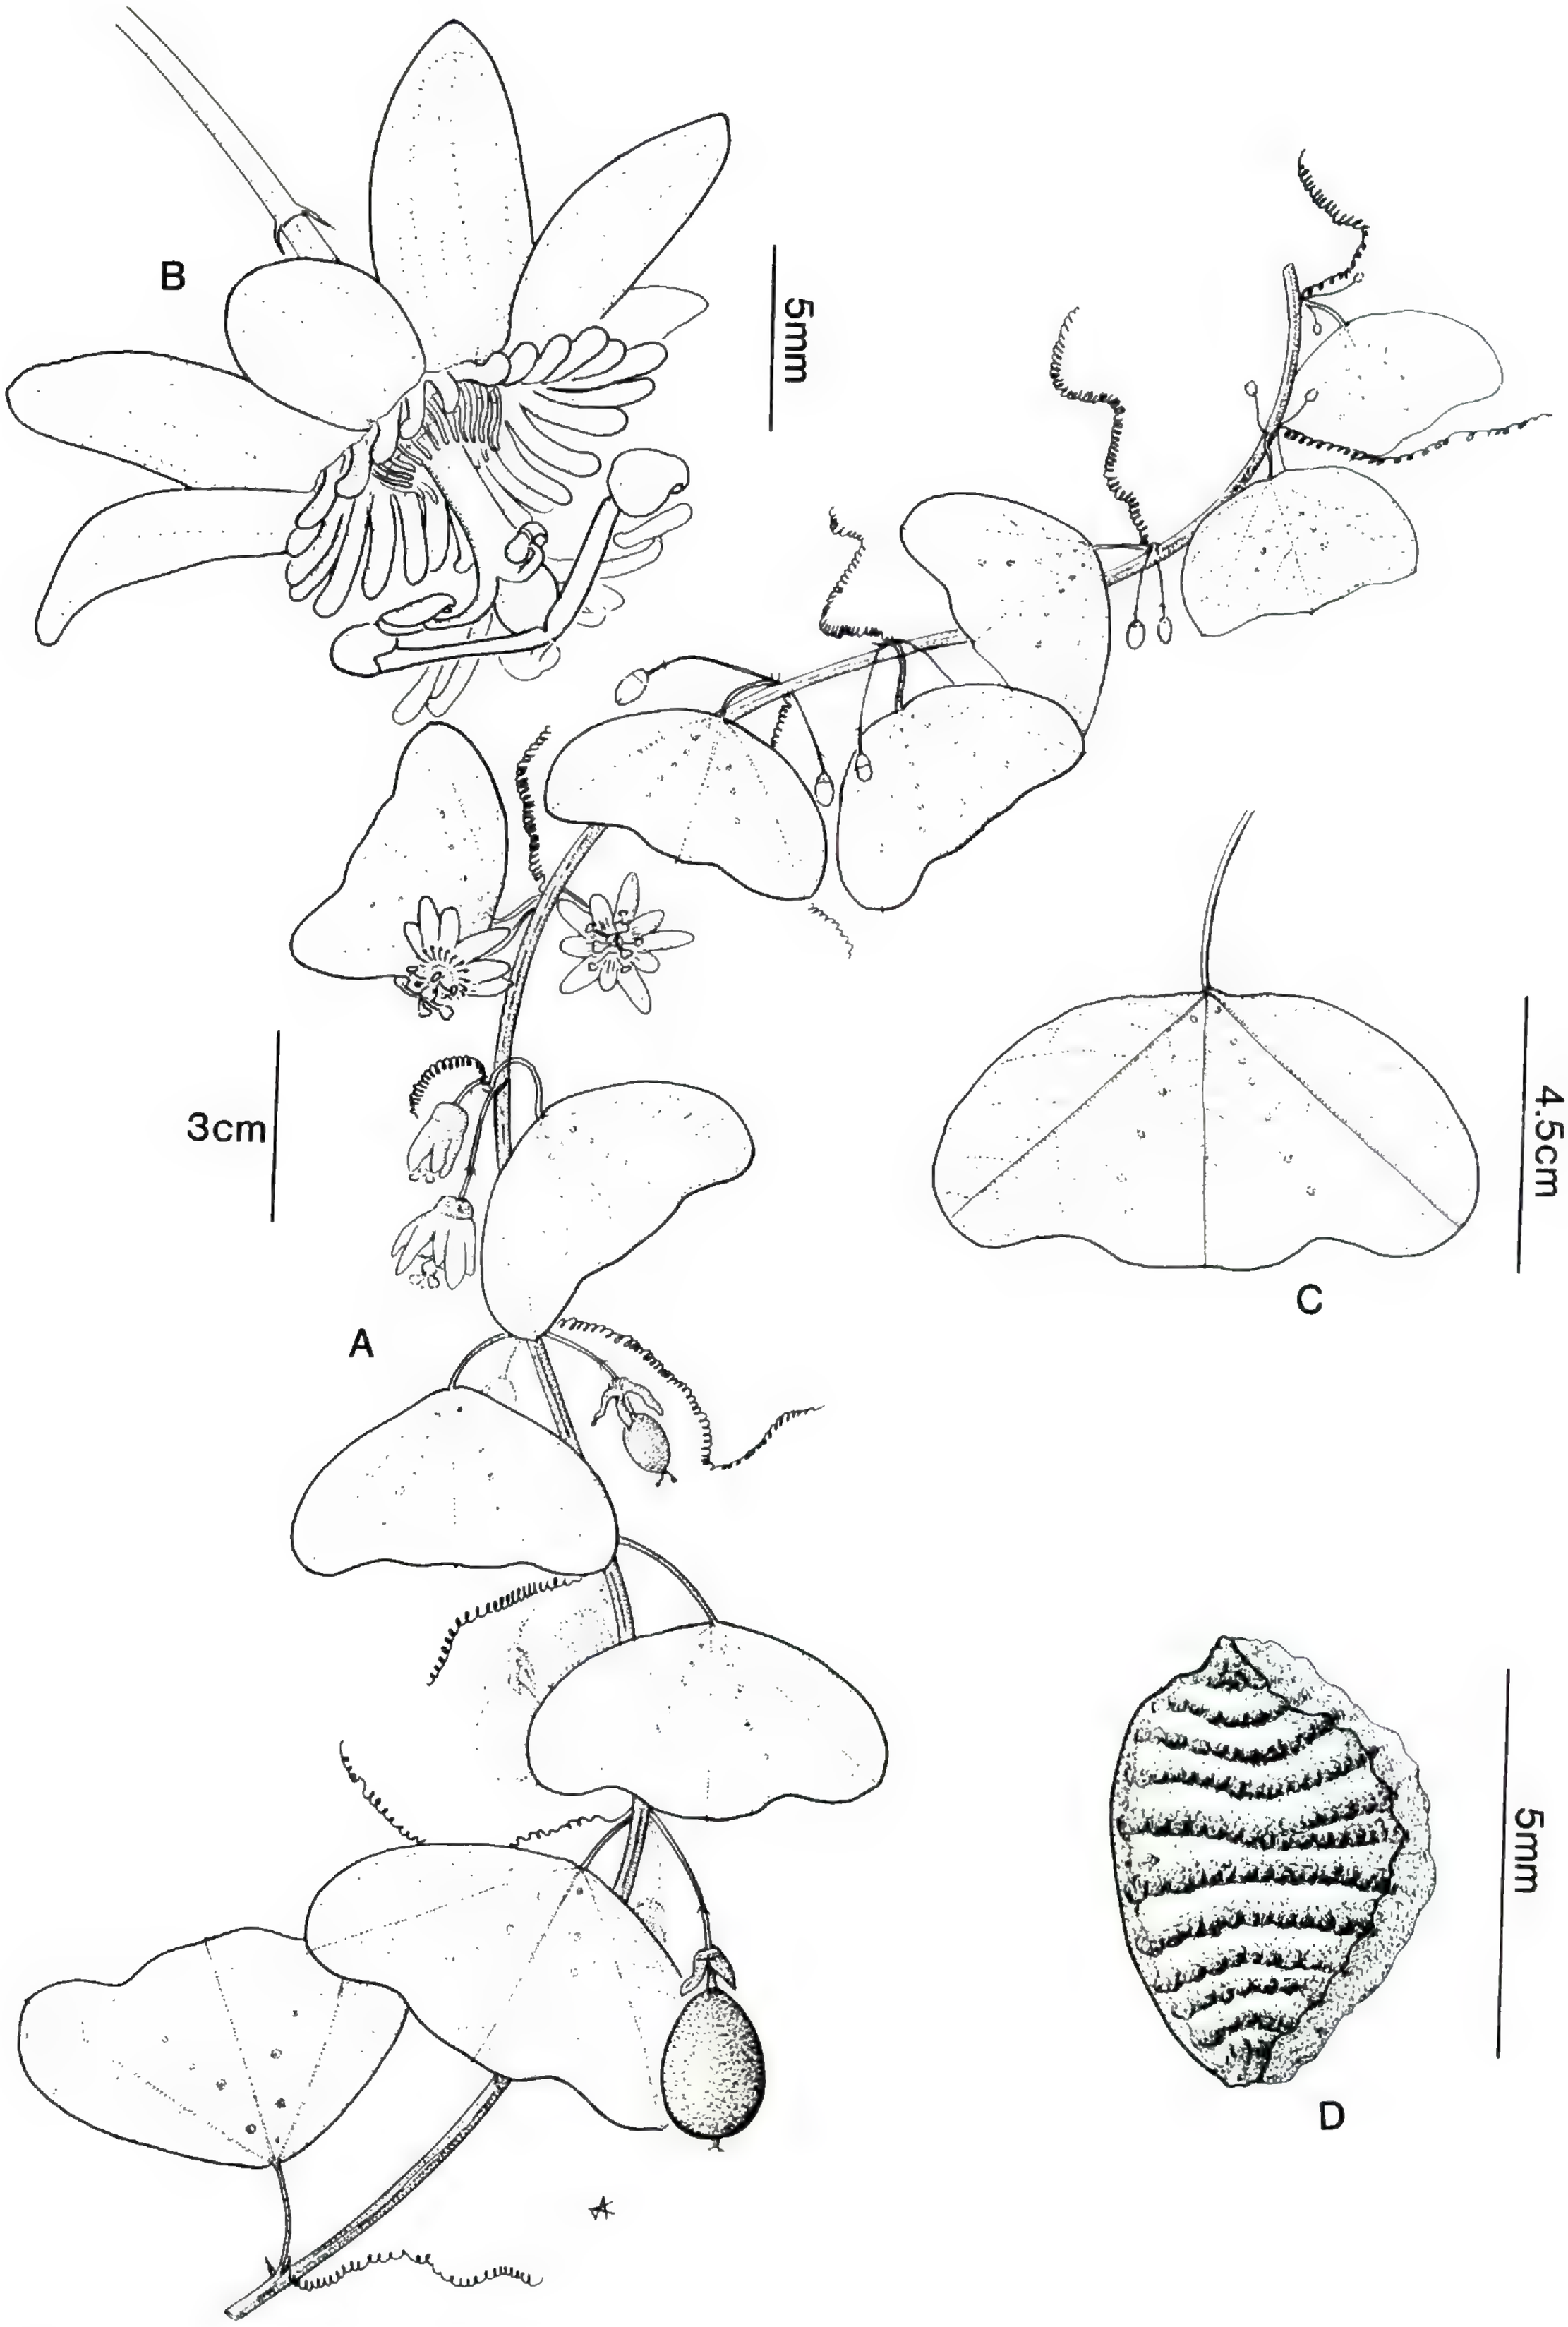

FIGURE 1. *Passiflora nubicola.*—A. Habit (*MacDougal 220GR*).—B. Flower (*MacDougal 220GR*).—C. Large leaf (*Brenes 6158*).—D. Seed with raphe (*Dryer 460*).

nous, plicate, pale yellow-green; nectary-trough without a raised annulus; limen (disk) ca. 2.5–2.7 mm diam., not colored or spotted; staminal filaments connate for 4.7–5.9 mm along the very pale green androgynophore, the free portions ca. 3–4 mm, pale yellowish green; anthers 2.2–2.5 mm, not marked with purple; ovary 2.0 × 1.8–2.0 mm, widely obovoid to widely ellipsoid, glabrous, light yellow green; styles ca. 4–5 mm, light yellow green; stigmas 1.5–2.4 mm diam., capitate. Fruit 1.8–2.5 × 1.8–2.1 cm, widely ellipsoid to very widely obovoid, obtusely trigonous in cross section, exocarp purplish or bluish black, glaucous, mesocarp spongy, white; arils no longer than seeds, clear, gelatinous; seeds 3.6–4.2(–4.5) mm long, 2.5–2.9 mm wide, 1.5–1.6 mm thick, obovate (to widely obovate), very slightly obcampylotropous (or nearly symmetric), transversely sulcate with (7–)8–10 sulcae, the ridges verrucose or knobbed, the chalazal beak erect to slightly inclined away from raphe. Chromosome number $n = 6$.

Additional specimens examined. COSTA RICA. ALAJUELA: Finca Johanson, Los Angeles de San Ramón, [ca. 10°09′N, 84°29′W], 11–12 Mar. 1928 (fl), *Brenes 6019* (F); camino de Finca Johanson, Los Angeles de San Ramón, 4 May 1928 (fl), *Brenes 6158* (F); road to Peñas Blancas from Monteverde ca. 2 km from continental divide, Atlantic slope, 1,400 m, 13 Apr. 1981 (fl, fr), *Knapp & Mallet 857* (TEX); road to Peñas Blancas ca. 3–4 km from divide, Atlantic slope, 1,300 m, 13 Apr. 1981 (fl), *Knapp & Mallet 858* (TEX). CARTAGO: Tapantí, 1,300–1,700 m, 26 Oct. 1983 (fl), *Chácon et al. 1530* (CR); ca. 1 km N and downstream of the junction of the Río Dos Amigos and the Río Grande de Orosi on the road to Tapantí, 1,500 m, 10 Aug. 1980, *MacDougal 1244* (DUKE). PUNTARENAS: vertiente Pacífico, Reserva, Monteverde, 1,520–1,580 m, 17 July 1976 (fr), *Dryer 460* (CR, F); 14 June 1977 (fr), *Dryer 1449* (F); 27 Aug. 1977, *MacDougal 220* (DUKE).

This small and inconspicuous passionflower is known from four areas of lower montane rainforest in Costa Rica. *Passiflora nubicola* grows at edges of primary forest, in treefalls, or along trails, where its thin wiry dark green stems trail over fallen logs and among grasses, bushes, and small trees. The leaves are similar in shape to those of a juvenile *P. biflora* Lam., and their flecks of white variegation are similarly distributed. The flower also resembles that of a miniature *P. biflora*, but in the Orosi valley possesses only one row of coronal filaments. The species is closely related to *P. biflora*.

At the Monteverde Reserve, the main herbivore of this species is *Heliconius clysonimus* (J. Mallet, pers. comm.).

The clone from the same plant as the holotype of this species was grown at Duke University 1977–1983, and the chromosome count was determined from the clones of this plant. Floral anthesis was around 0830 hrs. in the greenhouse, with the flowers closing in the early afternoon. No fruits were set by autogamy during cultivation, and more than 40 attempts at self-pollination also failed to produce fruit. *Passiflora nubicola* was very fertile in both directions with *P. biflora* (*MacDougal 260GR & 275GR*), yielding well-seeded fruit and vigorous F_1 progeny. Those progeny, generally morphologically intermediate in vegetative and reproductive character states, had variously malformed flowers and were sterile, producing no viable pollen. Fruits (with hybrid embryos) produced on *P. nubicola* matured in 45–48 days and contained 35–64 seeds per fruit (N = 13 fruits).

The epithet means "cloud-dweller," in reference to its habitat of misty forest.

Passiflora gilbertiana MacDougal, sp. nov. TYPE: Costa Rica. San José: along roadcut 18.2 km S of Villa Mills on Pan-American Highway, 7,700 ft, 10 Aug. 1977, *L. E. Gilbert 8* (holotype, LL; isotypes: F, MO, MSC). Figures 2, 3B.

Passiflora scandens; petioli eglandulosi; folia supra vittata, infra purpureata vel atrovinoseata, bilobata vel trilobata, lobis lateralibus acuminatis vel acutis, interdum rotundis, lobo centrali acuto vel obtuso, raro rotundo, interdum obsoleto, angulo inter lobos laterales 13–21°, lobis lateralibus quam centrali subaequalibus vel brevioribus, marginibus integris; bracteae 0.8–4.5(–5.7) mm longae; flores parvi virelli et aurei erectiusculi, odorem stercoreum exhalentes; coronae filamenta uniseriata vel biseriata, filamentis exterioribus filiformis, aureis, 5–7 mm longis; operculum plicatum; ovarium pubescens; semina 6–8 sulcata.

Perennial climber 2–4 m long, minutely ± puberulent throughout (except laminas) with (0.06–)0.10–0.15(–0.20)-mm suberect or slightly antrorsely appressed trichomes, the shoot tip densely minutely puberulent, becoming moderately (to sparsely) puberulent below. Stem 1.5–5 mm diam., with normal secondary growth below, subterete (drying angular), striate; posture of shoot tip cernuous; phyllotaxy 2/5. Stipules (1.7–)2.5–4.5(–6.0) × (0.2–)0.3–0.5(–0.7) mm, falcate, narrowly lanceolate to linear-triangular, very dark purplish, distally stramineous, yellow, or brown and necrescent. Petioles 0.8–3.5 cm (to 5 cm in juveniles), eglandular, adaxially puberulent, abaxially glabrous or sparsely puberulent. Laminas (4–)6–13(–17.5) × (1.7–)2.5–6.5 cm at fertile nodes, elliptic to narrowly obovate or oblong-obovate in general outline, adaxially glabrous or nearly so with a few trichomes proximally on primary veins, olive

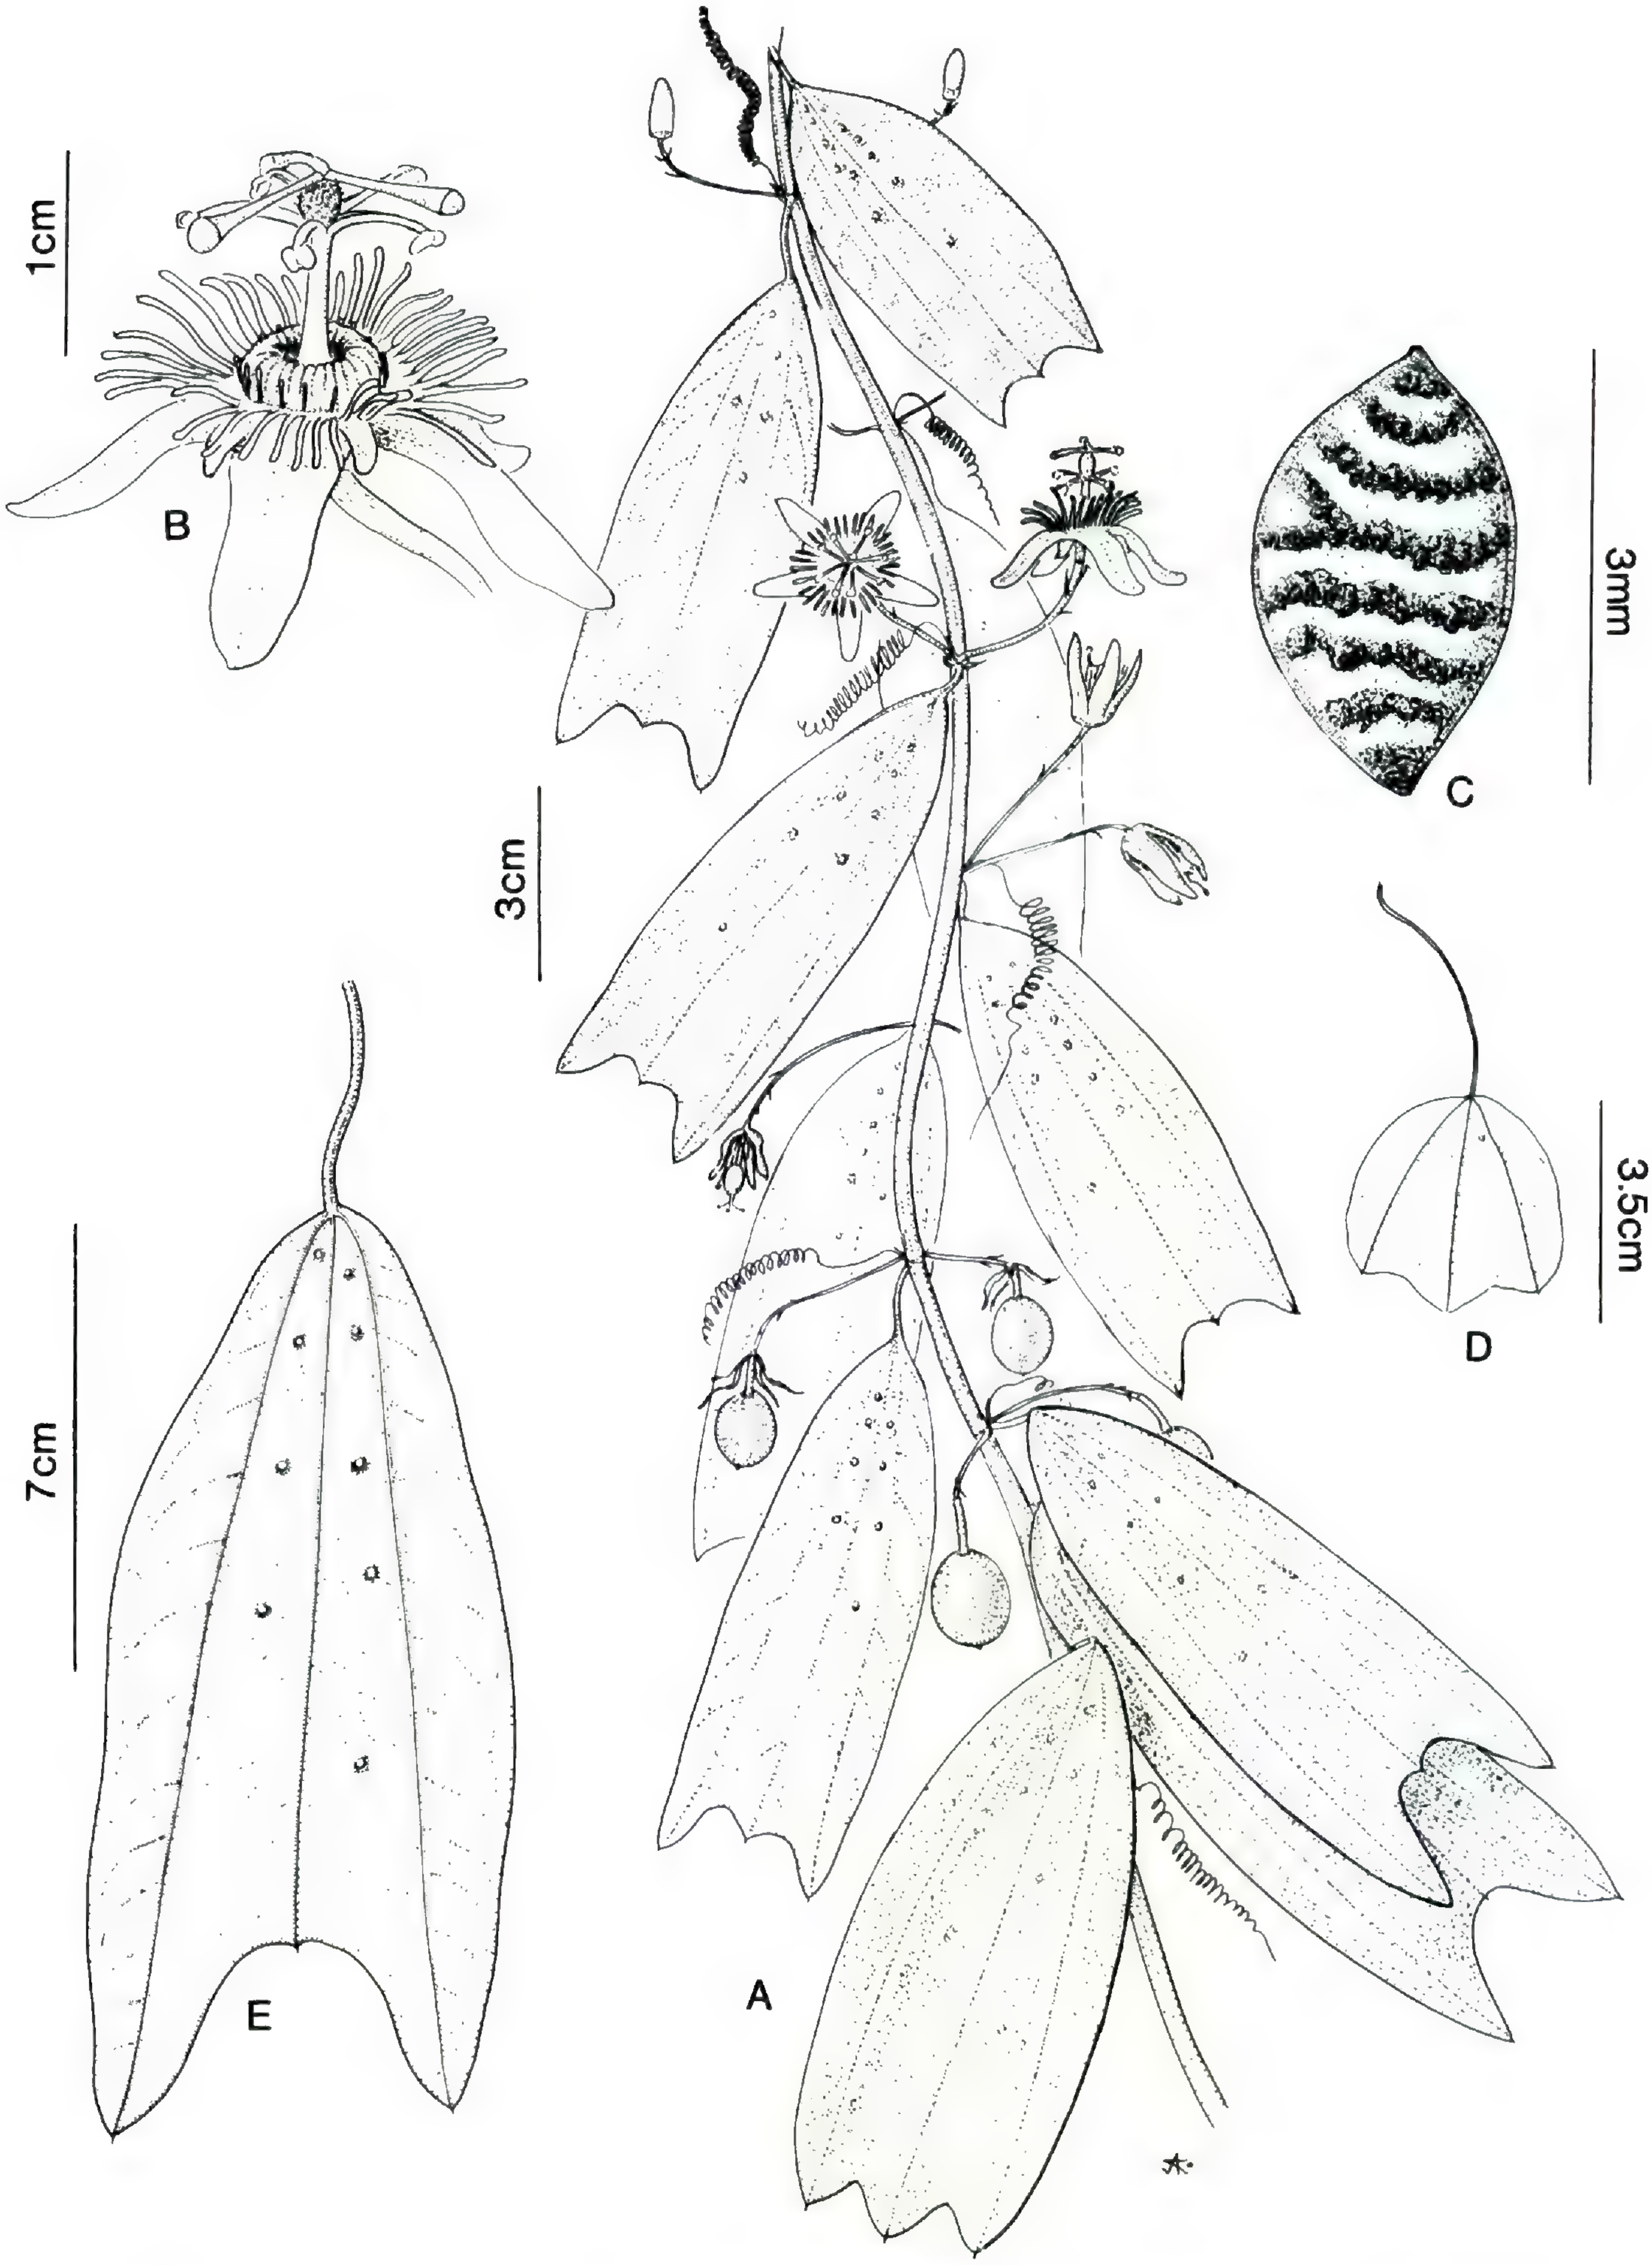

FIGURE 2. *Passiflora gilbertiana*.—A. Habit (*MacDougal 655*).—B. Flower (*MacDougal 655*).—C. Seed (*Gilbert 8*).—D. Leaf of seedling (*MacDougal 1432*).—E. Large leaf from below reproductive nodes (*MacDougal 1431*).

green or flushed purplish, striped with white or pale greenish yellow the length of the 2 lateral veins and sometimes along the basal part of the central vein, abaxially sparsely puberulent to glabrescent with trichomes mainly restricted to the primary and secondary veins, very deep purplish red to very dark reddish purple, becoming greenish on older leaves, the margins entire, puberulent to sparsely puberulent with 0.06–0.10-mm trichomes, very shallowly 3-lobed or shallowly 2-lobed for 0.04–0.15(–0.25) the distance to the cuneate to obtuse (or narrowly rounded) base, the lobes acuminate to acute, sometimes rounded at the very apex, or the central lobe obtuse to obsolete, the angle between the primary lateral veins 13–21°, the ratio of lateral to central vein lengths 0.94–1.2(–1.3), the ratio of laminar width to length 0.35–0.50; laminar nectaries (5–)9–14(–17) per leaf (fewer on seedlings), borne abaxially between the primary veins, ocellate with purple border, appearing light yellowish adaxially, the most proximal pair not strictly axillary or enlarged; leaves of juvenile plants similar, to 18 × 10 cm, with slightly larger lobe angle and relative width; leaves of seedlings with lobe angle 40–60°, central lobe on first leaves longest, then subequal in length, nearly as wide as long. Tendrils straight during development at shoot apex. Prophyll of vegetative ramifying bud 1, broadly lanceolate and often tridentate, acuminate, very dark purple. Peduncles 2.4–3.8(–4.4) cm, geminate, uniflorous; bracts 3, (0.8–)1.7–4(–5.7) × (0.1–)0.2–0.4 mm, linear-triangular, very dark purplish proximally, stramineous, yellowish, or brownish and necrescent apically. Flowers ca. 2 cm diam., suberect, pale greenish with a golden corona, with a strong putrid odor of scatole; floral stipe 4.0–6(–8.0) mm; hypanthium 6 mm diam.; sepals 11–15 × 3.0–4.5(–6.0) mm, narrowly triangular-oblong or lanceolate-oblong, rounded, ecorniculate, lightly but evenly puberulent to apex, very light yellow green on both sides; petals 2.0–3.5 × 1.0–1.5 mm, narrowly oblong-ovate to ovate, rounded, very light yellow-green; filamentous corona in 1–2 series, the outer filaments ca. 46–50, 5–7 mm, strongly spreading and only slightly and simply curved, cylindrical and gradually slightly ampliate toward the rounded apex, pale yellow, yellow-green, or whitish basally, the remainder vivid yellow; the inner filaments (if present) 0.6–1.2 mm, expressed mainly in the sepal sectors, slightly clavate, erect; operculum 1.8–2.4 mm, membranous, plicate, cream to yellow; nectary-trough without raised annulus; limen (disk) ca. 2 mm diam., pentagonal, bright yellow; androgynophore pale at base, dark pink to grayish purplish red distally; staminal filaments connate (6.2–)7.5–8(–9.0) mm along androgynophore, the free portions 5–6 mm, dark pink at base, light yellow-green distally; anthers 2.0–2.2 mm, not marked with purple; ovary 1.8–2.5 × 1.4–2.1 mm, widely ellipsoid to subglobose, densely puberulent, dark green; styles ca. 6 mm, light yellow green; stigmas ca. 1 mm diam., clavate-capitate. Fruit 1.2–1.4 cm diam., subglobose to widely ellipsoid, lightly puberulent, purplish or bluish black; arils translucent white, length unknown; seeds (2.9–)3.1–3.3 mm long, 1.9–2.1 mm wide, 1.1–1.2 mm thick, obovate, nearly symmetric to very slightly campylotropous, transversely sulcate with (6–)7–8 sulcae, the ridges coarsely verrucose or knobbed, the chalazal beak very slightly inclined toward raphe.

Additional specimens examined. COSTA RICA. SAN JOSÉ: clone of Gilbert's type collection cultivated at Duke University 1980–1984, *MacDougal 655* (BM, CR, DUKE, HUA, MEXU, TEX); from type locality, Aug. 1980, *MacDougal 1431* (CR, DUKE, MO), *1432* (DUKE); side roads along the Pan-American Hwy. ca. 10–15 km N of San Isidro de General, near kms 118–116, at the crossing of the Río Paymer, and N along the road from there, 1,500–1,600 m, 8 Aug. 1981, *Taylor 1120* (DUKE); along the Interamerican Hwy. above San Isidro de General, ca. 15 km N at river crossing, 1,500 m, 5 Mar. 1985, *Taylor & Skotak 4771* (DUKE, MO).

Passiflora gilbertiana is remarkable for its variegated reddish purple leaves and stinking golden flowers. It is a member of a species group of Central American passionflowers in section *Decaloba* characterized by bilobed variegated leaves, greenish to yellow perianth, filiform unbanded outer coronal filaments, and notable reduction in the size of the petals relative to the sepals. This group is part of section *Decaloba* but was not recognized by Killip (1938), who scattered its component species among several of his invalid "series" of section *Decaloba*. Within the group, the new species is most closely related to *P. jorullensis* H.B.K. of Mexico, *P. apetala* Killip of Costa Rica and Panama (Fig. 3), and an undescribed relative of *P. apetala* from the mountainous border of Mexico and Guatemala. Its distinctive characteristics include its long narrow leaf with a relatively small interlobe angle and more strongly expressed red to purple coloration, retention of conspicuous laminar variegation at maturity, and yellow flower with small petals and second (inner) series of coronal filaments. The inner series of coronal filaments varies as to presence or absence within the species. In *Taylor & Skotak 4771* the series is well developed, numbering ca. 40; in the type it is absent. However, the cultivation of somatic clones (*MacDougal 655*) from the type plant revealed that the expression of the second

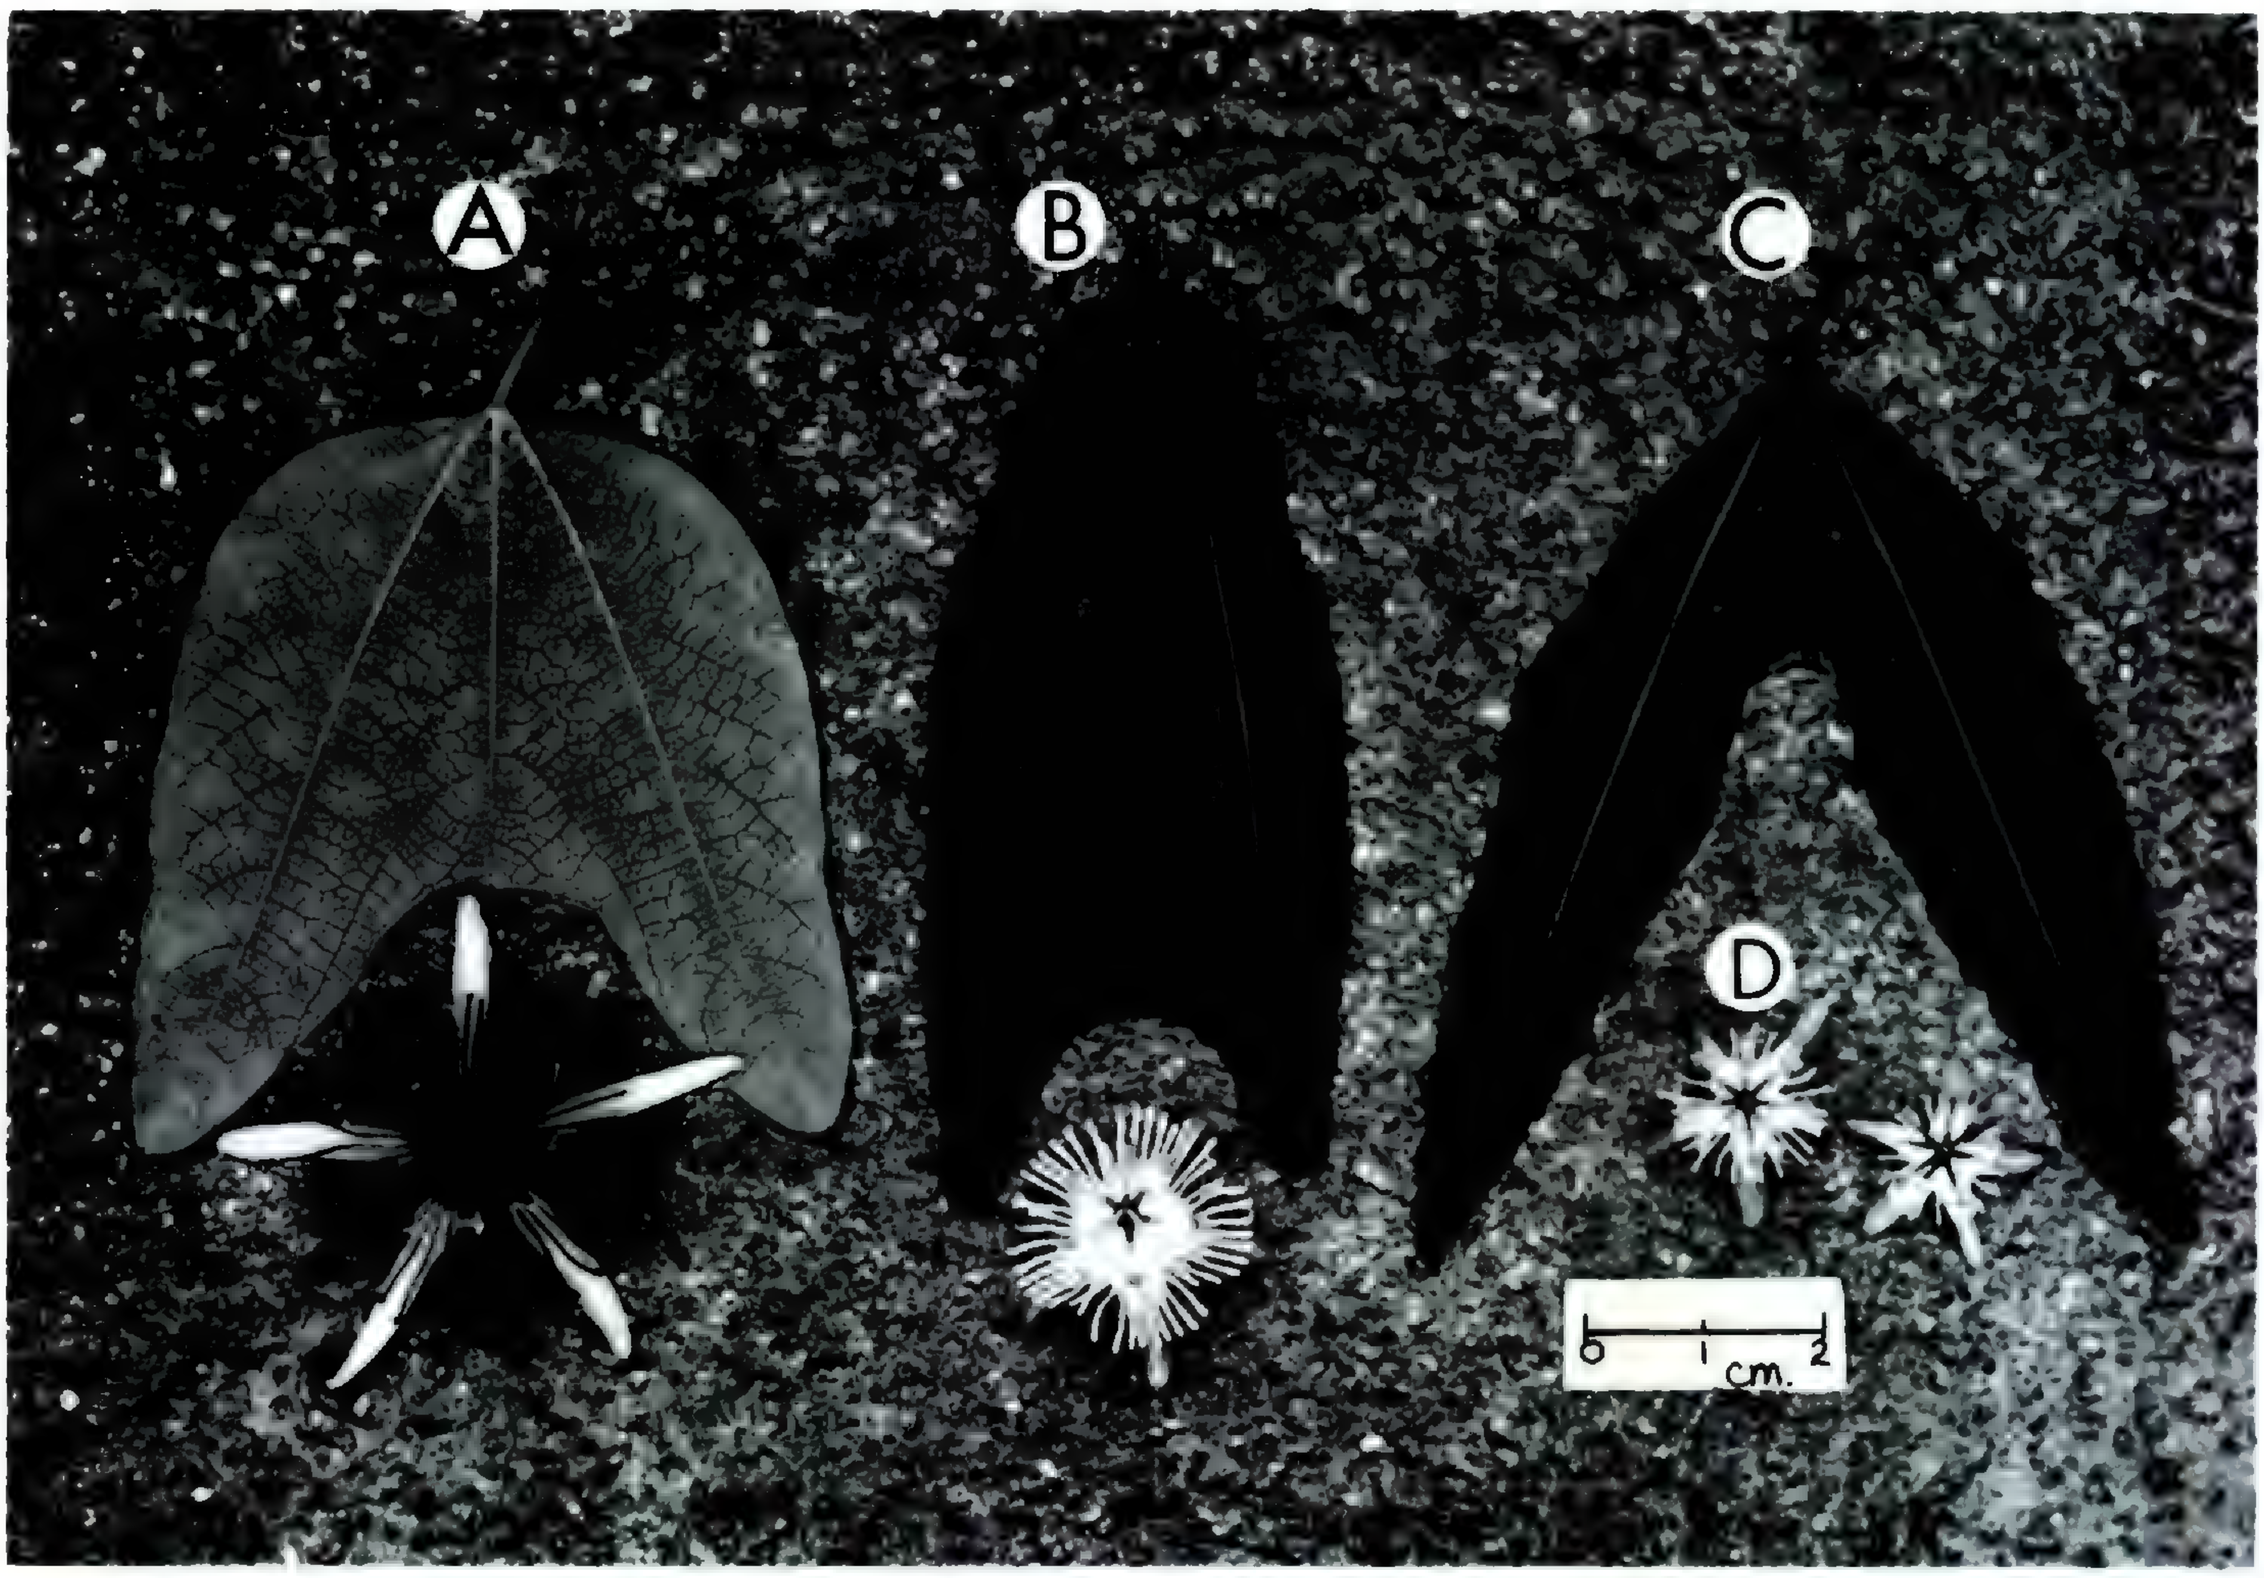

FIGURE 3. Comparison of leaves and flowers of three closely related species.—A. *Passiflora jorullensis* (*MacDougal 368*).—B. *Passiflora gilbertiana* (*MacDougal 655*).—C. *Passiflora apetala* (*MacDougal 467*).—D. *Passiflora apetala*, flower only (*MacDougal 450*).

filamentous series was variable within this individual, with (0–)5–12(–20) filaments per flower. The expression changed gradually along the stem, at times stronger, at times weaker, perhaps dependent on environmental conditions. In certain cases the expression seemed to be related to the position of the flower on the vine, with smaller flowers near the end of flowering axillary branches completely lacking the second series.

On the label of the type is the collector's note "odor of pigpen." The flowers of this new species share this strong odor (described as between "stercoraire et putride" by Planchon, 1849) with *P. jorullensis* (pers. obs.). Gilbert also noted on the type label "visited by hummingbirds," but the same day he also observed a single wasp at a flower (pers. comm.). It is thus probably significant that *P. jorullensis*, with a nearly identical odor, is primarily wasp-pollinated at least in some part of Mexico (MacDougal, unpubl.).

The habitat at the type locality is treefalls and partially shaded thickets along a dirt road on steep slopes in the lower reaches of *Alnus* forest. Plants there climbed over bushes and trailed into small *Alnus* and *Piper* trees. An important herbivore at the type locality is a yellow flea beetle that is an undescribed species of *Monomacra* (from *MacDougal 1431*, voucher identified by C. Duckett, deposited in the Cornell University Insect Collection). Several of the cited specimens show characteristic damage by flea beetles.

A clone from the type collection was cultivated at Duke University and from there was distributed to several commercial greenhouses in California and made available for sale to the public by 1980. In cultivation the plant bloomed from the morning to afternoon, with anthesis around 0930 hrs. and flower closing in mid to late afternoon. The stigmas, although lowered to anther level into the afternoon, were not receptive after ca. 1230 hrs. No fruits were set by autogamy during cultivation, but during limited hand-pollinations, 6 of 11 self-pollinations before 1230 hrs. produced mature fruit containing 19–31 seeds per fruit.

Mr. Patrick Worley, a commercial plant hybridizer, crossed a clone of the type with *P. biflora*, *P. ornithoura* Masters (*MacDougal 623*), and *P. jorullensis* (*MacDougal 368*); many F_1 progeny were grown to maturity and all flowered. Pollen viability was not examined. In each case the unpleasant odor was conserved. One especially ornamental individual of the cross with *P. jorullensis*

was named "Sunburst" and has been available to the public from several nurseries since 1983.

I take great pleasure in naming this species for its discoverer, Lawrence E. Gilbert of The University of Texas at Austin, whose seminal contributions to the understanding of the ecology of the Passifloraceae and their herbivores are well known. Dr. Gilbert first suggested the study of passionflowers to me and has aroused and guided an interest in these plants in many other students. It is particularly gratifying to name this plant because I had the privilege of being with Dr. Gilbert the day he discovered it and gathered the type collection. He immediately suspected it to be undescribed and his exuberance kindled in me what has become a career.

Many of the observations given here were made at Duke University, and I gratefully acknowledge Donald E. Stone for his inspiration and guidance during my graduate studies. Thanks are due the Organization for Tropical Studies for their summer field course that introduced me to Lawrence Gilbert and to these Costa Rican passionflowers. The staff of the Duke University greenhouses provided many years of favorable conditions for passionflower vines, and the Jessie Smith Noyes Foundation generously provided postdoctoral support for research on this family at the Missouri Botanical Garden. The drawings were prepared by John Myers.

PASSIFLORA MAYARUM, A NEW SPECIES RELATED TO *P. PROLATA* IN SUBGENUS *PASSIFLORA* (PASSIFLORACEAE)

Collections from Central America made since the time of Killip's (1938) monumental monograph of the American Passifloraceae have allowed a clearer delineation of a number of taxa, and in some cases have confirmed his suspicions that certain specimens might represent undescribed species. Such is the case with *Passiflora prolata* Masters and its apparent sister species newly described here.

Passiflora mayarum MacDougal, sp. nov. TYPE: Mexico. Quintana Roo: roadside secondary scrub 3 km N of San José de la Montaña on road N of Tomás Garrido (ca. 75 km W of Chetumal), 100 m, 9 May 1982, *Chater et al. 89* (holotype, MO; isotype, BM). Figures 1A, C, 2.

Passiflora (subgenus *Passiflora*) scandens, puberula, trichomatibus 0.05–0.25 mm longis; stipulae 10–22 × 0.4–1.0 mm; petioli 2(–4)-glandulosi; folia trilobata, lobis acuminatis vel caudatis, marginibus serratis vel serrulatis; bracteae 4.8–6.6 × 2.0–3.4 cm, ovato-ellipticae, acuminatae; coronae filamenta 6–8-seriata; operculum ad apicem in lacinias divisum; ovarium glabrum vel raro puberulum. *Passiflora prolata* affinis est.

Vine, size unknown, puberulent throughout except glabrous or nearly so on tendrils, adaxial surface of lamina, flowers, and sometimes adaxial surface of bracts. Trichomes 0.05–0.20(–0.25) mm, erect and straight or curved. Stems subterete to obtusely subangular, striate, apparently not hollow. Stipules (10–)13–18(–22) × 0.4–1.0 mm, linear-narrowly oblanceolate (or linear-triangular to linear-narrowly lanceolate), long-attenuate, tardily deciduous, glandular-denticulate; petioles 2(–4)-glandular ¼–¾ the distance to the appex (or if 4-glandular, rarely 1 pair near the apex), the nectaries sessile or up to 1 × (0.7–)1–2.2 mm, (crateriform to) patelliform; laminas 10–13 × 9–14 cm, glandular-serrate(-serrulate), not variegated, glabrous adaxially except the primary veins puberulent at least half their length, 3-lobed for 0.4–0.7 the distance to the base, the lobes lanceolate to narrowly ovate-oblong, acuminate to short-caudate; laminar nectaries marginal, 2–5 slightly enlarged teeth borne in each lobe sinus, enlarged teeth absent at base of lamina. Prophylls of vegetative ramifying bud 2, 1–2 mm long, lanceolate, equal or one smaller. Peduncle 1 per node, 1.5–4(–5.0) cm, uniflorous; bracts 4.8–6.6 × 2.0–3.4 cm, valvate in bud, free to the base, ovate-elliptic, conspicuously 2–4(–6)-glandular at the margin basally, otherwise entire or the basal ½ obscurely glandular-denticulate, acuminate to long-acuminate, yellow green, deciduous in fruit, adaxial surface puberulent or glabrous with puberulent main veins and a narrow band of tomentum along margin, the venation basally acrodromous with prominent intramarginal veins. Perianth white, longest coronal filaments purplish to violet, white at the apex, banded white basally; floral stipe ca. 12–14 mm (to 20 mm in fruit); hypanthium ca. 5–6 mm long, ca. 13–14 mm diam., puberulent; sepals 24–34 × 7–12 mm, lanceolate-triangular, puberulent, sometimes only sparsely so, subapically with an arista (8–)10–18 mm; petals 24–34 × 6–9 mm, oblong-lanceolate; coronal filaments in 6–8 series, the 2 outermost similar, often apically tortuous, the outer 26–32 mm, the second series broader at their base and ca. 3–6 mm shorter, the next (3–)4–5 series tuberculate or 1–5(–7) mm, the innermost series 6–10 mm, banded purple and white; operculum basally connate for 2–4.5 mm, membranous, the margin erose or short-fimbriate and often slightly plicate, with a subapical and slightly deflexed series of fimbriae or filaments 1–3(–5) mm long; nectar ring (annulus) present in the middle of the nectary; limen (disk) ca. 6–8 mm diam. around the widely broadened base of the androgynophore, ca. 3 mm above the floor of the nectary; staminal filaments connate 10–13 mm along androgynophore, the free portions 8–9 mm, glabrous; anthers 10–12 mm; ovary 5–6.5 × 2–3.2 mm, narrowly ovoid-ellipsoid, glabrous (rarely sparsely puberulent); styles 10–11 mm including stigmas, glabrous; stigmas 4 mm wide, deeply bilobed. Fruit 7.5–9 × 4.5–5 cm, ellipsoid, greenish

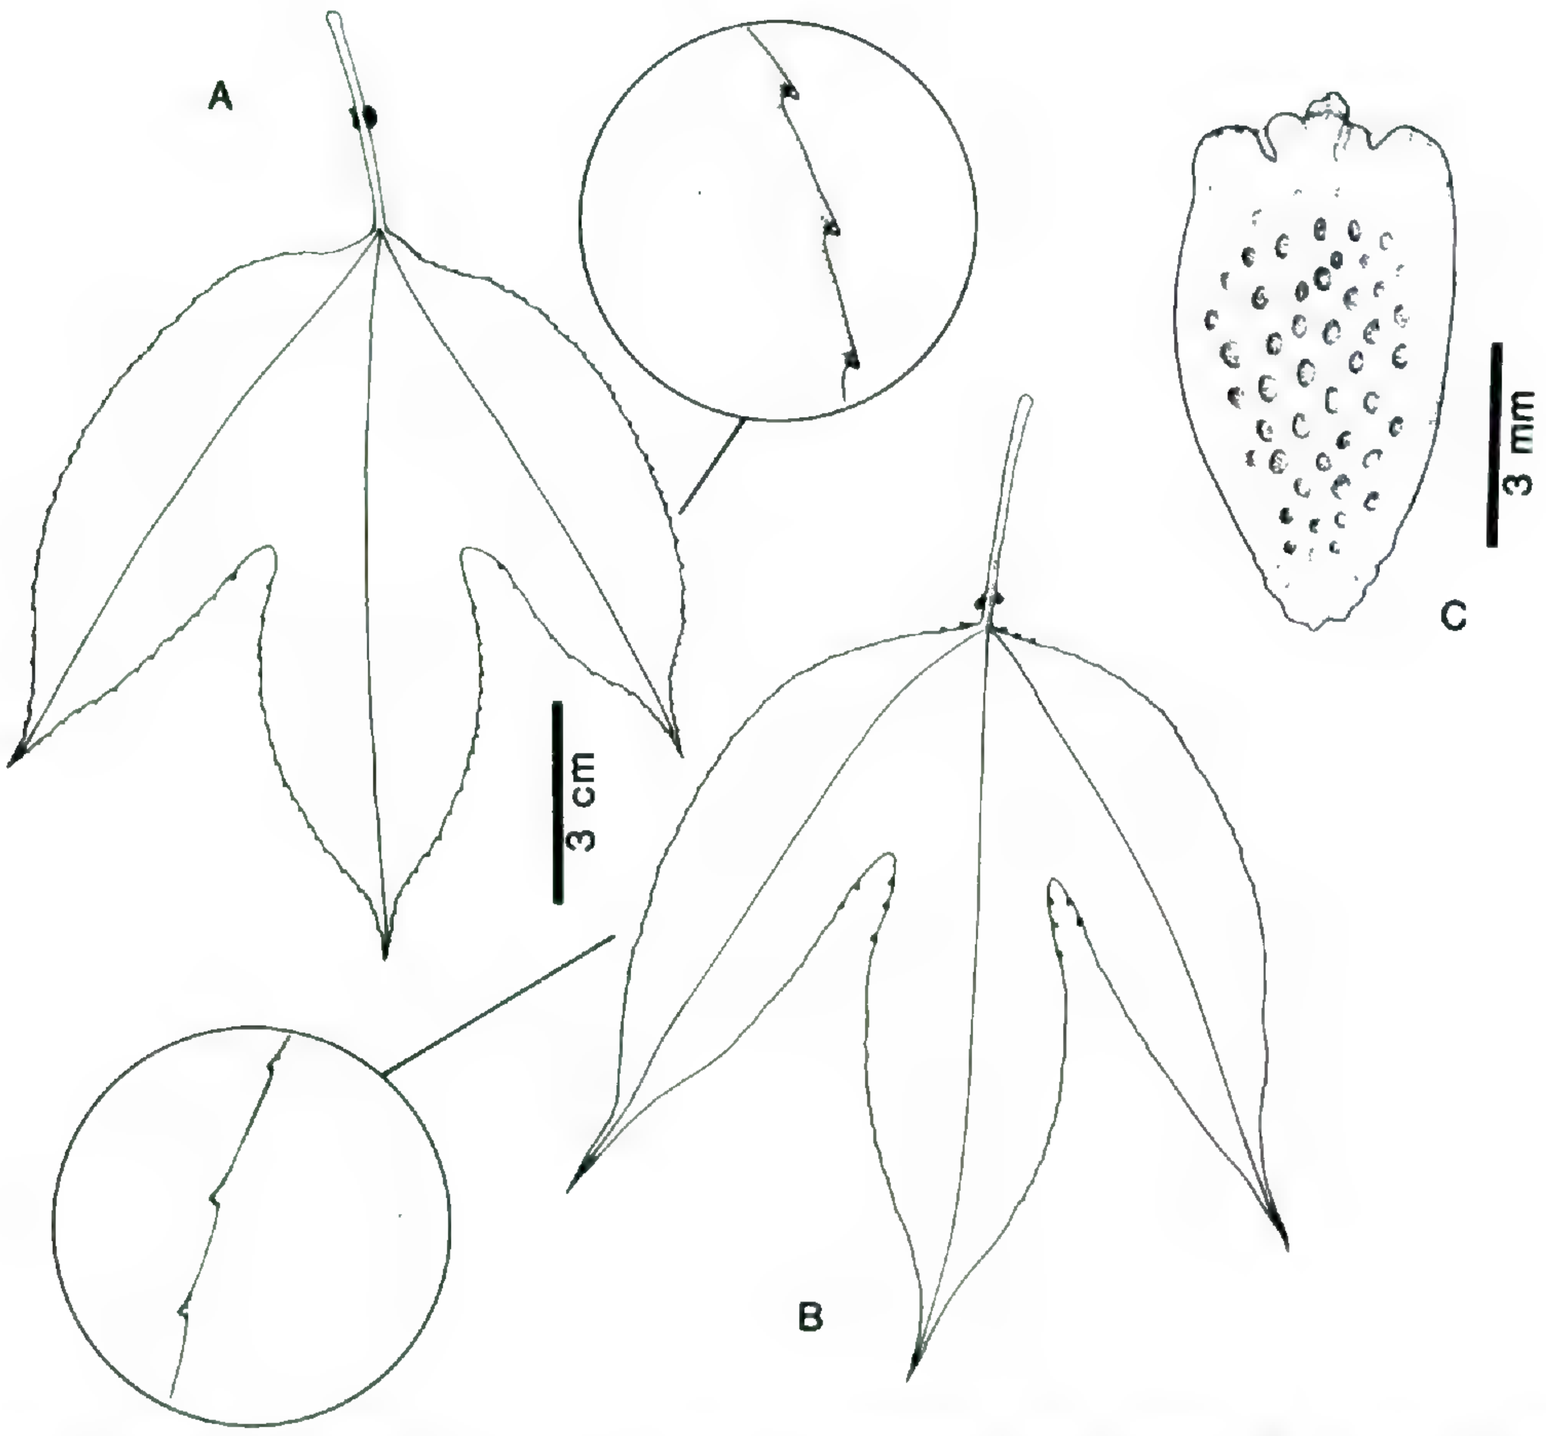

FIGURE 1.—A. Leaf of *Passiflora mayarum* with detail of marginal teeth (*Téllez & Cabrera 2429*).—B. Leaf of *P. prolata* with detail of marginal teeth (*MacDougal 596*).—C. Seed of *P. mayarum* (*Téllez & Cabrera 2429*).

yellow to yellow, estipitate; arils longer than the seeds, color and flavor unknown; seeds 7.2–8.0 mm long × 4.0–4.5 mm wide × 1.9 mm thick, obovate, strongly compressed, nearly bilaterally symmetric with the chalazal end squared and shallowly 3-dentate, brown, reticulate-foveate with 35–46 foveae.

Habitat and distribution. This species grows in the Caribbean lowlands of northern Guatemala, western Belize, and the southern part of the Yucatán Peninsula (Fig. 2). The collections come from elevations of 20–250 m, except for two collections from one station at 550 m in Belize. The habitat is usually open or partially open vegetation. Although the information is not present on the specimen's label, Bartlett (1935: 20) stated that his collection *12840* was collected in the wooded swamp vegetation called *escobal*, which is a vegetation type dominated by the *escoba* palm, *Cryosophila*. This edaphic climax occurs in the Petén and Yucatán on wet soil surrounding water holes ("aguadas") and as the transitional zone between the inundated areas of the wooded swamps ("bajos") and the well-drained "high bush" uplands (Bartlett, 1935; Lundell, 1937). However, most of the collections are from disturbed and more well-drained habitats, namely, roadsides and secondary areas in low forest, *selva mediana subperennifolia*, or *selva alta subperennifolia* (Rzedowski, 1978).

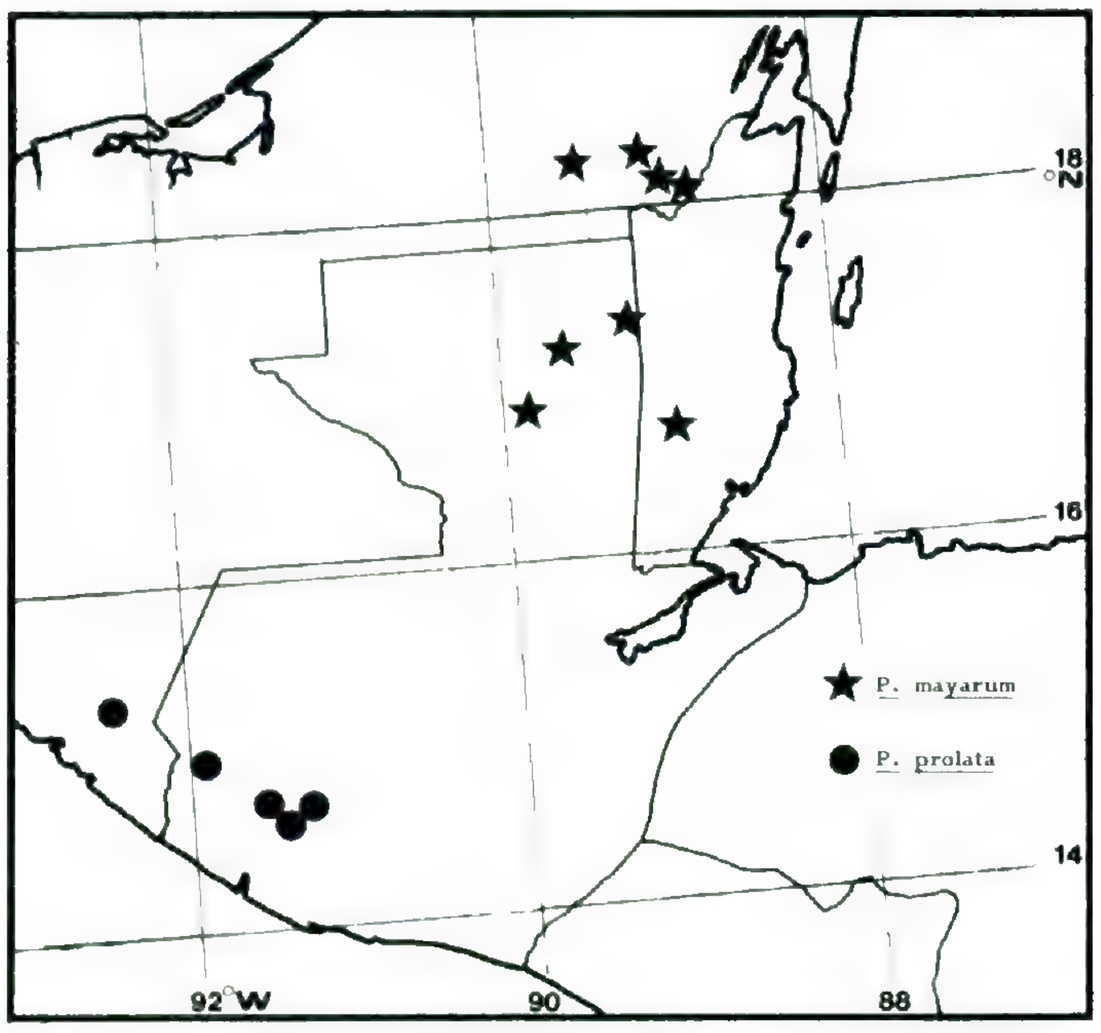

FIGURE 2. Map of Guatemala, Belize, and neighboring countries showing distributions of *Passiflora mayarum* and *P. prolata*.

Phenology. The few collections known suggest that reproduction occurs primarily during the wet season from April through November. One sheet, however, was collected in flower at the end of December. Although the type has nearly mature fruit, fully mature fruit and seeds are known only from *Téllez & Cabrera 2429*.

Vernacular name. "Granadilla" (*Tún O. 372*).

Additional specimens examined. MEXICO. CAMPECHE: 30 km al S de Xpujil, 22 Apr. 1982, *Cabrera & Cabrera 2482* (MEXU, MO). QUINTANA ROO: 8 km al S de Tres Garantias, sobre el camino a Tomás Garrido, 22 Dec. 1982, *Cabrera & Cabrera 4174* (MEXU, MO); 24 km al N de La Unión, 7 May 1980, *Téllez & Cabrera 2100* (MEXU, MO); 15 km al S de Ejido Laguna OM, 8 June 1980, *Téllez & Cabrera 2429* (MEXU, MO). BELIZE. CAYO: between Millionario and Cuevas, 30 May 1973, *Dwyer 10823* (MO); vic. Millionario, 1,800 ft., 30 May 1973, *A. Gentry 7733* (MO). GUATEMALA. PETÉN: Dos Arroyos to Yal'och, 2 May 1931, *Bartlett 12840* (MICH, US—fragment; photos: F, NY, US); ca. 5 mi. S of Tikal National Park, 19 June 1973, *Dwyer 11269* (MEXU, MO); S of Tikal National Park, 19 June 1973, *A. Gentry 8338* (MO—2 sheets, US); camino de El Remate en el Km 59, Parque Nacional de Tikal, 24 Oct. 1969, *Tún O. 372* (F, NY, US); Santa Elena, en el camino para San Andrés, Km 4, lado saliente, 4 Oct. 1969, *Tún O. 1374* (F).

Passiflora mayarum is most similar to and is undoubtedly very closely related to *P. prolata* from the premontane to montane broad-leaved forests of the Pacific watershed of Guatemala and Chiapas, Mexico. Except for the vestiture, the two have similar leaves and nearly identical glandular bracts. At the time of his 1938 monograph, Killip knew *Passiflora prolata* only from the type. He knew the related species newly described here from a single collection by Bartlett (*12840*). He had identified that sheet as *P. prolata* (Killip, 1936), but later expressed some misgivings. In his monograph (1938: 389) he stated, "I am referring the Bartlett collection to *P. prolata* with some hesitation, as the stem and under surface of the leaves are puberulent and the petiolar glands are not quite as in the type. It comes, moreover, from the lowlands." The more recent collections of both species confirm that the two are separate morphologically and ecologically. Neither fruit nor seeds are known from *P. prolata*, so it is impossible to compare the two species on these points. They may be distinguished by the following key.

1a. Stems and leaves glabrous except for slight pubescence or puberulence at the nodes, on the sides of the adaxial primary laminar veins, and sometimes on the petiole. Stipules 7–10 mm long, acuminate. Petioles glandular in the distal half, the glands 0.3–0.8 mm diam. and usually longer than wide. Laminar lobes conspicuously long-acuminate; laminar margin serrulate, often only denticulate apically, usually nectariferous at the junction of the petiole. Bracts glabrous abaxially. Hypanthium and sepals glabrous. Habitat elevation 700–2,000 m ..... *P. prolata*

1b. Stems and leaves puberulent except the lamina glabrous adaxially with the primary veins puberulent. Stipules 10–22 mm long, long-attenuate. Petioles glandular at a variable position, the glands 0.7–2.2 mm diam. and wider than long. Laminar lobes acuminate to short-caudate; laminar margin uniformly serrate (to serrulate), not nectariferous at the junction of the petiole. Bracts puberulent abaxially. Hypanthium puberulent, sepals puberulent or only sparsely so. Habitat elevation 20–550 m ..... *P. mayarum*

Not having seen the type of *P. prolata* (*Lehmann 1630*—G-BOIS), I have relied on the protologue and five more recent collections, including one of my own, that match the protologue. Three of these collections were identified as *P. prolata* by Killip (who saw the type), and one was collected within 30 km of the type locality at a similar elevation. The flowers of *P. prolata* and *P. mayarum* appear to be rather similar, apparently borne above the horizontal plane, with two prominent series of purplish outer coronal filaments, several reduced intermediate series, and a well-developed inclined inner series. The operculum in both is similar, although that of *P. mayarum* has shorter subapical filaments. I have seen the flower of *P. prolata* only from *Matuda 16479* (F), in which the intermediate coronal series are reduced to variably expressed series of tubercles. It is not possible to determine clearly the relative length of the two outer series except to say that they are roughly similar in this poorly pressed specimen. Given the lack of comparative reproductive material and the coronal variation that occurs within related species, I have for now distinguished the two species mainly by vegetative characteristics.

The leaves of *P. mayarum* tend to be less deeply lobed, but there is considerable overlap with *P. prolata*. The quality and quantity of the indument differ: the few trichomes that occur on the leaves and nodes of *P. prolata* are ca. 0.2–0.4 mm instead of 0.05–0.25 mm long. Despite the variation in their vestiture, the bracts of both species always have a narrow band of dense tomentum along the margin adaxially. The trichomes are crispate, and those of adjacent bracts are interlocked during the development of the bud, keeping the bracts valvate. This marginal band of crispate tomentum occurs in number of species of *Passiflora* and is correlated with foliaceous valvate bracts. The ovary of *P. mayarum* is glabrous in all collections examined except *Tún O. 1374*, in which it is sparsely puberulent.

Some of the Mexican collections of the new species were distributed as *P. platyloba* Killip and are cited as such in Sousa & Cabrera (1983).

Passiflora mayarum and *P. prolata* belong to subgenus *Passiflora*, where they share characteristics with species that Killip (1938) included in his informal "series" *Serratifoliae* and *Incarnatae*.

Killip placed *P. prolata* next to *P. incarnata* L. as one of six species in *Incarnatae*, which was distinguished within subgenus *Passiflora* (as subgenus "*Granadilla*") as having unwinged stems, free bracts, narrow stipules, lobed leaves, eglandular sepals, filamentous corona in more than two series, petiolar glands present, and denticulate or fimbriate operculum. That delineation is fraught with difficulties since most of those character states are undoubtedly plesiomorphic for the subgenus. Except for the lobed leaves, it also fits the species put in the *Serratifoliae* group. An understanding of the relationships among these species and the granadillas as a whole awaits a revision of subgenus *Passiflora*. *Passiflora mayarum* is probably genetically close enough to the commercially important *P. edulis* Sims to warrant investigation into using it as a rootstock or as a source of genetic improvement for the commercial passionfruit. It is especially notable that *P. mayarum* has been collected growing in warm wet soil, the kind of conditions that induce fungus-related failure of the commercial crop.

The epithet *mayarum* refers to the native distribution of this species, centered in the heart of the Mayan Old Empire.

I am grateful to the Jessie Smith Noyes Foundation for postdoctoral support for research on passionflowers, to the curators of the herbaria listed above, and to John Myers for the drawing.

TWO NEW SPECIES OF *TOURNEFORTIA* (BORAGINACEAE) FROM COLOMBIA

Recent collecting efforts in western Colombia have yielded two very distinct and undescribed species of *Tournefortia* L. Both are members of sect. *Tournefortia*, a pantropical group with its center of diversity in Andean South America. Species of *Tournefortia* from this area remain confused, since the most recent taxonomic treatment available is de Candolle's (1845). Macbride (1960) covered the species from Peru, but his treatment is regional and incomplete. Killip prepared an unpublished treatment of the Andean species. The following two species are new.

Tournefortia brantii James S. Miller, sp. nov. TYPE: Colombia. Antioquia: Mpio. Valdivia; road to Briceño, 1.1 km W of the Medellín–Caucasia highway, pasture, and secondary forest adjacent to road, 7°03′N, 75°28′W, 1,800 m, *A. E. Brant & O. Escobar 1293* (holotype, MO 3531269). Figure 1.

Arbor parva ad 3 m alta, ramunculis villosis. Folia opposita, ovata ad elliptica, 9–17 cm longa, 5–9.5 cm lata, apice acuminato, basi cuneata ad decurrenti, supra pubescentia, infra villosa. Inflorescentia cymosa, bis dichotome ramosa, pedunculo 4–11 mm longo. Sepala lineari-lanceolata, 3–5 mm longa; corolla alba, 5 mm longa, lobis 5, ovatis, 1 mm longis, tubo 4–5 mm longo, strigoso. Fructus non visi.

Small tree 3 m tall, the twigs villous, the hairs erect, 1–2 mm long, brown. Leaves opposite; petioles 5–12 mm long, villous, the hairs erect, 1–2 mm long, brown; leaf blades ovate to nearly elliptic, 9–17 cm long, 5–9.5 cm wide, the apex acuminate, the base cuneate to decurrent, the margin entire but appearing ciliate from hairs of the upper surface, the secondary veins 8–9, ascending, arising from the midrib at 30°–50°, the tertiary and quaternary veins clearly visible on the lower surface, ramifying reticulately, the upper surface pubescent, the hairs erect, ca. 1 mm long, translucent white to clear, approaching villous along the midrib, the lower surface villous, densely so along the midrib and secondary veins. Inflorescence a twice dichotomously branched cyme, the peduncle 4–11 mm long, villous, the hairs erect, 1–2 mm long, brown, the fertile branches 3–9 cm long, the flowers borne densely at early anthesis, 1–2 mm apart, the fertile branches later becoming more lax, the flowers then 3–5 mm apart. Flowers bisexual, with the stigma borne beneath the anthers; sepals 5, free to the base, linear-lanceolate, 3–5 mm long, unequal in length, densely brown strigose; corolla white, tubular with 5 spreading lobes, 5 mm long, the lobes ovate, 1 mm long, the tube 4–5 mm long, brown strigose, densely so near the apex, sparsely so near the base; stamens 5, the anthers borne just beneath the mouth of the corolla tube, nearly sessile, ellipsoid, 0.8 mm long; ovary ovoid, 1 mm tall, the style 3 mm long, the stigma conical. Fruits unknown.

Tournefortia brantii is a member of sect. *Tournefortia* and belongs to a group of about 10 poorly defined species that have opposite leaves. These species occur from Costa Rica through Colombia, Ecuador, Peru, and into Bolivia and are centered in the northern Andes. While problems exist with species delimitation among the opposite-leaved species of *Tournefortia*, *T. brantii* is distinct among the South American species by having dark brown indument and sepals to 5 mm long. It is most similar to *T. johnstonii* Standley, a species of Panama (Miller, 1988), which differs in having sepals longer than 6 mm and a corolla tube 8–10 mm long. The other species of *Tournefortia* with opposite leaves in Colombia, *T. pauciflora* Nowicke and *T. scabrida* Kunth, differ in having shorter calyces and less prominant indument on the twigs (Nowicke, 1974).

Tournefortia spicata James S. Miller, sp. nov. TYPE: Colombia. Nariño: Mpio. Tumaco, 80 km from Tumaco along road to Pasto, in wet area of primary forest, near *Orbignya* palms and streams, "Guayacana," 19 July 1984, *M. J. Balick, L. E. Forero P., S. R. King & N. Hernández 1667* (holotype, MO 3531270). Figure 2.

MISSOURI
BOTANICAL GARDEN
HERBARIUM

№ 3531269

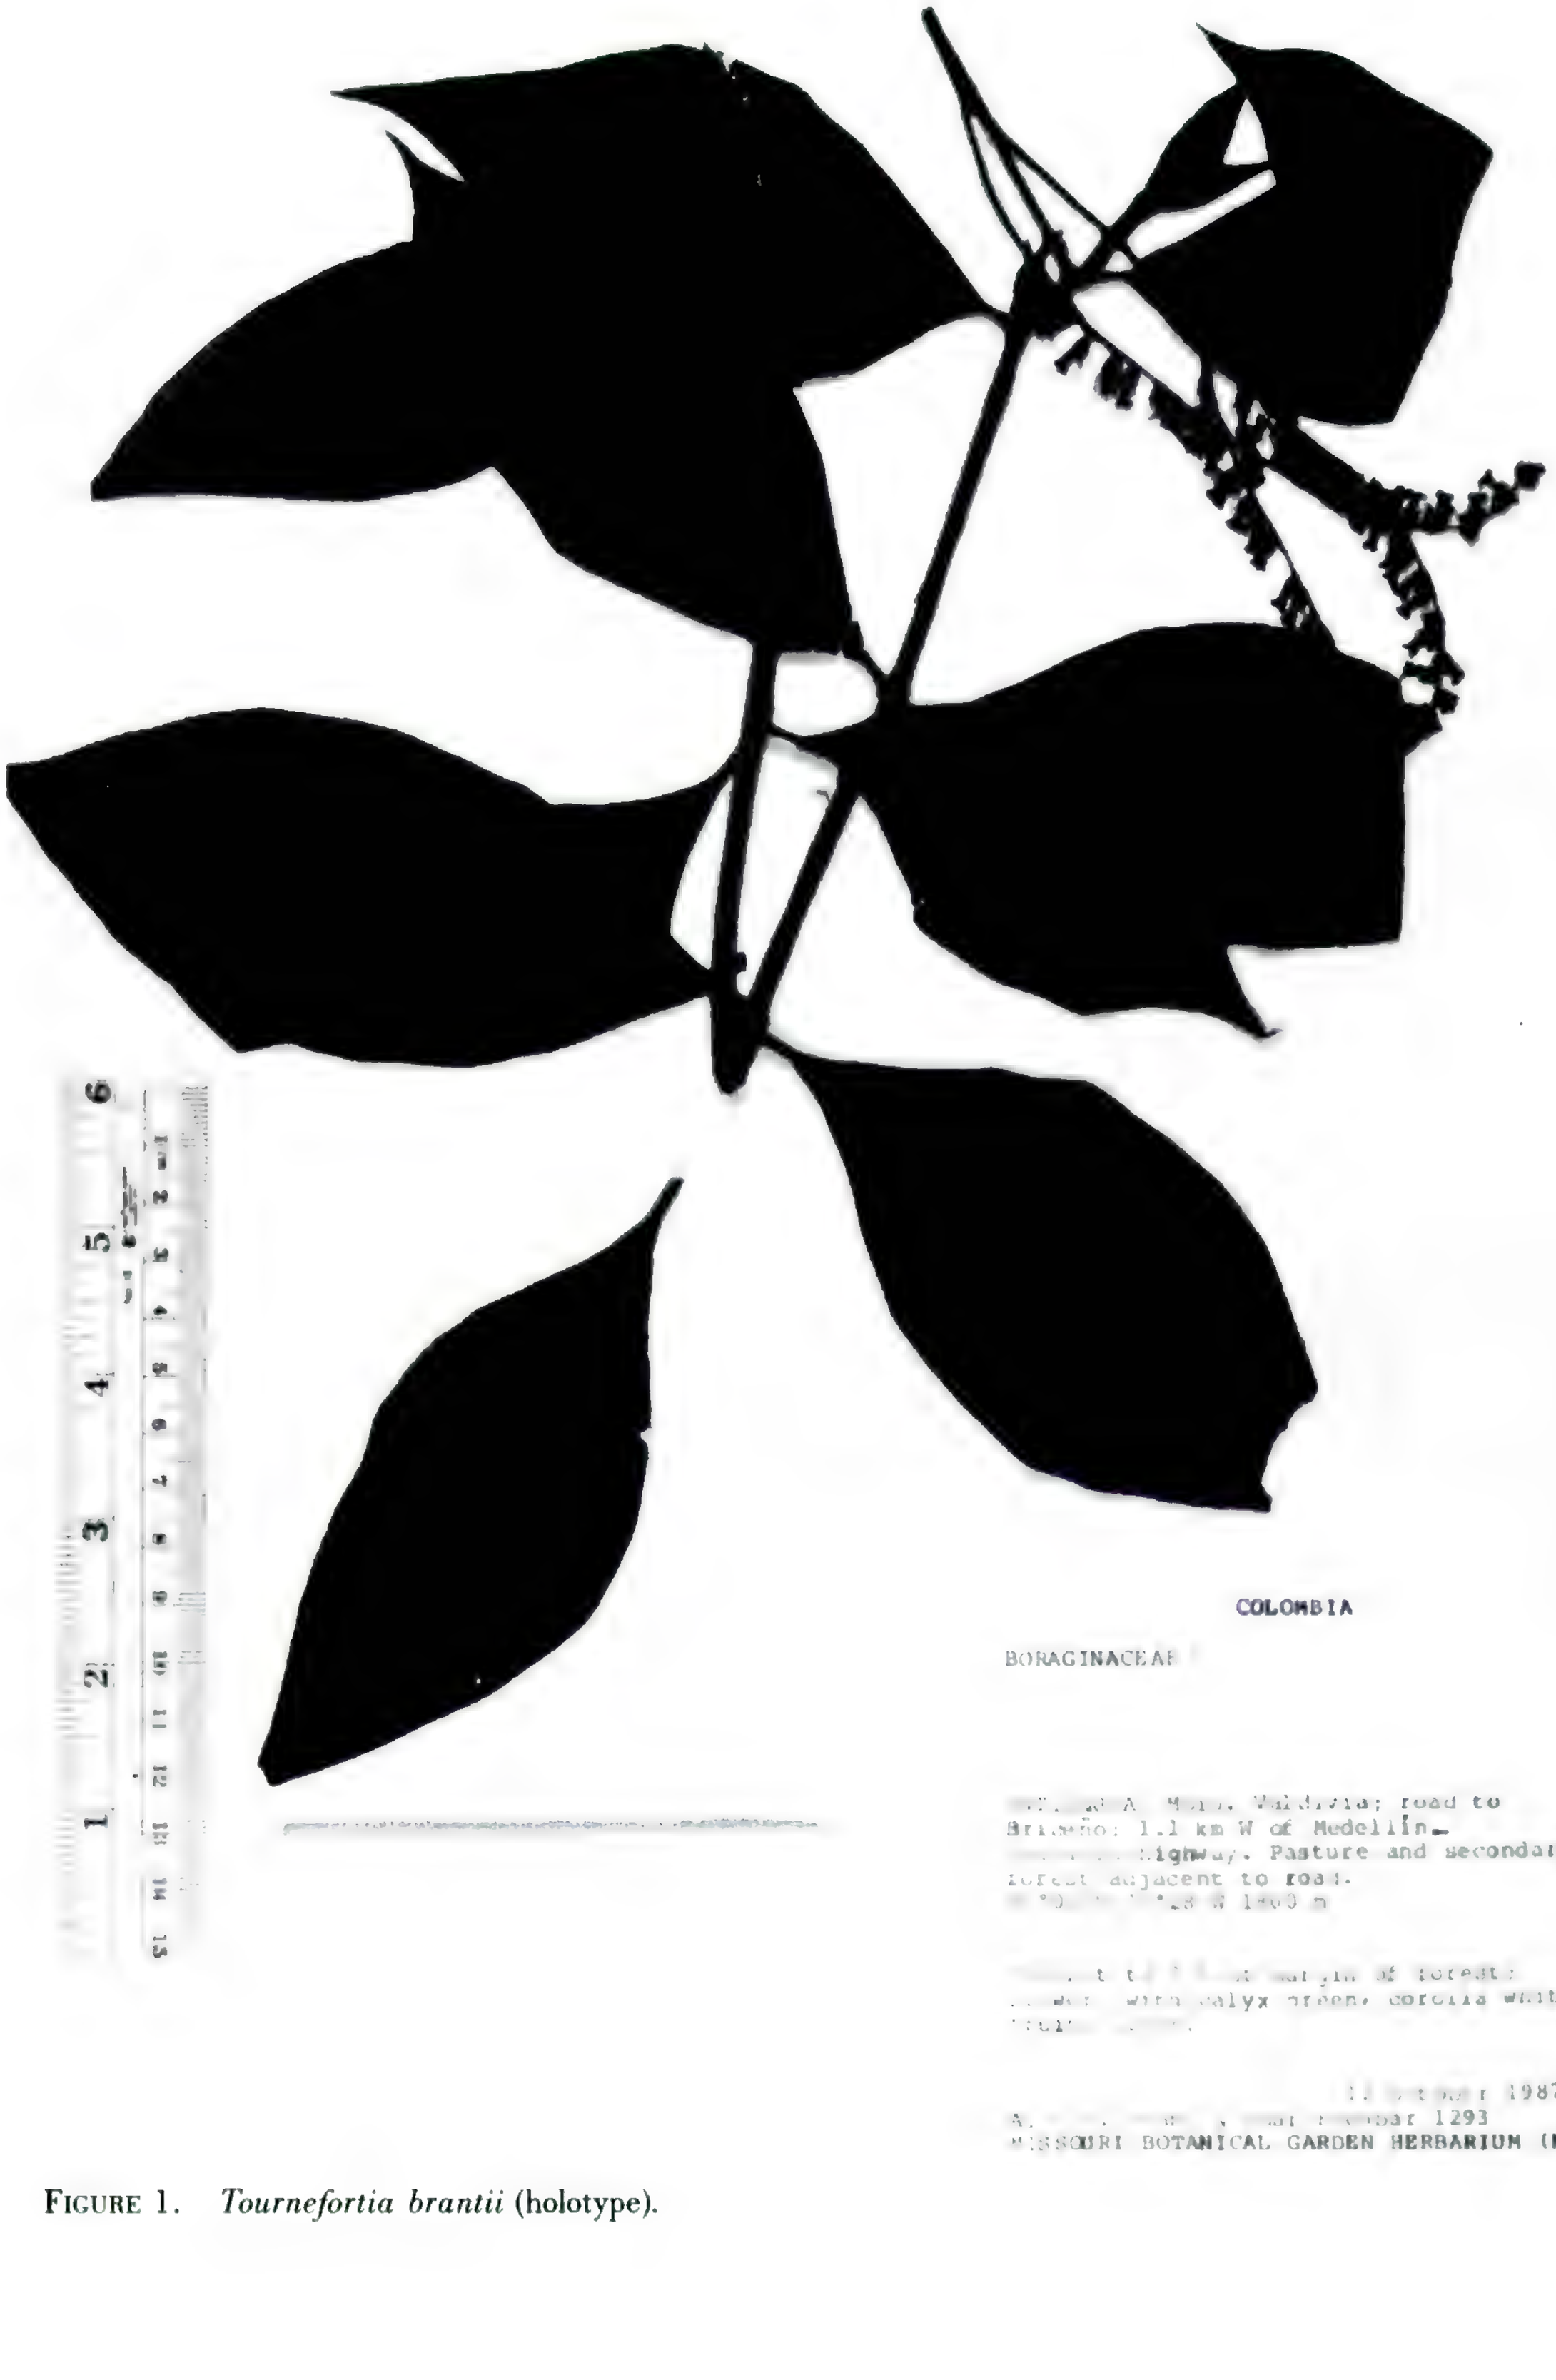

FIGURE 1. *Tournefortia brantii* (holotype).

FIGURE 2. *Tournefortia spicata* (holotype).

Frutex ad 3 m altus, ramunculis veluntinis ad villosis. Folia alterna, ovata, 14.5–21.5 cm longa, 8–10 cm lata, apice acuminato, basi obtusa ad late acuta, supra et infra hirsuta. Inflorescentia dense florifera, clavato-spicata. Sepala lineari-lanceolata, 4–5.5 mm longa; corolla lutea, postea nigra, 8 mm longa, lobis 5, ovatis, 2 mm longis, tubo 4–5 mm longo, hirsuto. Fructus non visi.

Soft-stemmed shrub to 3 m tall, the twigs velutinous to villous with erect golden-brown hairs ca. 1 mm long. Leaves alternate; petioles 11–28 mm long, velutinous, the hairs erect, ca. 1 mm long, golden brown; leaf blade ovate, 14.5–21.5 cm long, 8–10 cm wide, the apex acuminate, the base obtuse to widely acute and decurrent along the petiole for 0.5–1 cm, the margin entire, secondary veins 13–15, arising from the midrib at 70°–80° near the base of the leaf, 35°–40° near the apex, the tertiary and quaternary veins clearly evident, ramifying in a reticulate pattern, the upper surface hirsute, the hairs erect to spreading, arising from the aeroles only giving a slightly bullate appearance to the leaf at maturity, the midrib villous, the lower surface hirsute, villous along the midrib and secondary veins. Inflorescences densely spicate borne in pairs from a dichotomously branched peduncle 9–14 cm long, this velutinous to villous, the hairs erect, ca. 1 mm long, golden-brown, the spikes 5–8 cm long, 1.5–2.5 cm broad, the flowers borne 1 mm or less apart, a few scattered, 3–9 mm apart at the base. Flowers bisexual with the style borne beneath the anthers; sepals 5, free to the base, linear-lanceolate, 4–5.5 mm long, uneven in length, hirsute; corolla yellow, later turning black, tubular with 5 spreading lobes, 8 mm long, the lobes ovate and acuminate at the apex, ca. 2 mm long, the tube 4–5 mm long, hirsute outside; stamens 5, inserted just beneath the mouth of the corolla tube, the anthers nearly sessile, lanceoloid, ca. 1 mm long; ovary ovoid, ca. 0.6 mm tall, the style ca. 5 mm long, the stigma conical with a thickened annular ring at the base. Fruits unknown.

Tournefortia spicata stands apart from the other species of sect. *Tournefortia*, and its relationships are unclear. It is unusual in its soft-stemmed, short growth habit, dense inflorescence, and velutinous to villose peduncle. The flowers are distinctive in having linear-lanceolate sepals 4–5.5 mm long and a corolla tube 8 mm long, It is known only from the area in which the type was collected, and fruits remain unknown.

Additional specimens examined. COLOMBIA. NARIÑO: Mpio. Tumaco, La Guayacana, 20–100 m, *Soejarto 958* (US).

I thank the Department of Botany at the Smithsonian Institution, particularly Joan W. Nowicke, for providing E. P. Killip's unpublished manuscript.

A NEW SPECIES OF *URGINEA* (LILIACEAE) IN NIGERIA

The genus *Urginea* Stein. is represented in West Tropical Africa by the variable species *U. indica* (Roxb.) Kunth, *U. ensifolia* (Thonn.) Hepper, *U. pauciflora* Bak., and the variable *U. altissima* (L.) Bak., which was recently discovered to resolve into a complex of three species: *U. altissima* (L.) Bak., sensu stricto, *U. gigantea* (Jacq.) Oyewole, and *U. viridula* Bak. (Oyewole, 1975). Samples of wild populations continue to reveal the inadequacy of the existing taxonomy of the genus. For instance, complexes such as in *U. indica* (Oyewole, 1987) or entirely new variants are being discovered. Hence, a revision of the genus is due.

The present report describes a recently discovered wild population of a new species within the main campus site of the University of Ilorin, Kwara State, in west central Nigeria.

Ecology

The flora of a rock outcrop located about 1.5 km to the east of the academic area of the main campus site of the University of Ilorin, about 20 km outside the city of Ilorin, was first sampled in May 1982. The site of the rock was to be part of a proposed botanical garden.

About 100 tiny bulbs of an evidently new representative of *Urginea* were collected between May 1982 and February 1983, from the shallow soils of the outcrop. The soil is brown and lateritic, with occasional dark humus in depressions. The vegetation is low grassland, with few small trees of *Entada africana*, *Erythrina pulcherrima*, and other legumes interspersed with stands of *Butyrospermum paradoxum* and *Lophira lanceolata*, and low stands of *Cochlospermum* sp. Herbaceous species of Commelinaceae and Asteraceae are common among low grasses. Seasonal marshes and ponds support the growth of various Cyperaceae, *Anthericum nigericum*, and many low, herbaceous Acanthaceae and Scrophulariaceae.

Bulbs of *U. nana* occur in an unshaded area with low grass and forb cover. Other bulbous geophytes occurring in the same habitat and interspersed with *U. nana* are *Dipcadi tacazzeanum* (Hochst. ex A. Chev.) Bak. (*D. filamentosa* Morton) and *Pancratium hirtum* A. Chev.

Taxonomy

Urginea nana Oyewole, sp. nov. TYPE: Nigeria. Ilorin: near the academic area, University of Ilorin, *S00/2111* (holotype, IUH; isotype, FHI). Figures 1–3.

Bulbus ovoideo-globosus, circa 3 cm altus, 4 cm diam., collis bulborum 0.5–4 cm, tunicae albae, tunicis exterioribus maroribus; folia tenuia, filiformia appressa aut lineari-lanceolata, erecta, 8–20 cm longa, 1–3 mm lata; pedunculus erectus, 1.5–4 cm longus; racemus compressus umbellatus, floribus 1–6, pedicellis crassis sed non rigidis, postremo in fructu reflexis; tepala subpunicesubflavida, aut subviridula flavida, 6–10 mm longa, 1–2 mm lata; maginibus flavescentibus, antherae 1–2 mm longae; capsula globosa vel ovoidea fulva, apice mucronata, 8–12 mm longa, seminibus nigris vel fusco-fulvis, 7–8 mm longis, usque 4–6 mm longis et usque 6 mm latis. Affinis *Urginea pauciflora* et *Urginea indica* (formae depauperatae) sed pedunculis minoribus, racemo compresso usque umbellato, foliis filiformibus aut lineari-lanceolatis differt.

Bulb small, ovoid-globose, up to 3 cm high and 4 cm diam., usually with bulb neck, 0.5–4 cm long and consisting of rolled bases of old leaves; scales white, outermost tunics membranous; leaves thin, filiform and spreading, or linear-lanceolate and erect to acutely arching, 8–20 cm long, 1–3 mm wide, not borne with the flowers; peduncle stiffly erect, 1.5–4 cm high, naked; inflorescence compressed, 1–6-flowered, all arising from about the same level terminally; pedicel thick but not stiff, reflexed during fruit development; tepal 6, pinkish and tinged yellow at the margin, or greenish yellow with hyaline margin, in 2 whorls of 3 each, alternating and free to the base, 6–10 mm long, 1–2 mm broad, outer segments reflexed at anthesis; filament hyaline, anthers bicelled, dorsally medifixed and versatile, up to 2 mm long, completely fertile; ovary pyramidal, 3–4 mm high at anthesis; style short and stiffly erect, about as long as the ovary. Fruit a 3-chambered capsule, brownish at maturity, ovoid-spherical, with mucronate apex, only slightly trigonal from the exterior, 8–12 mm

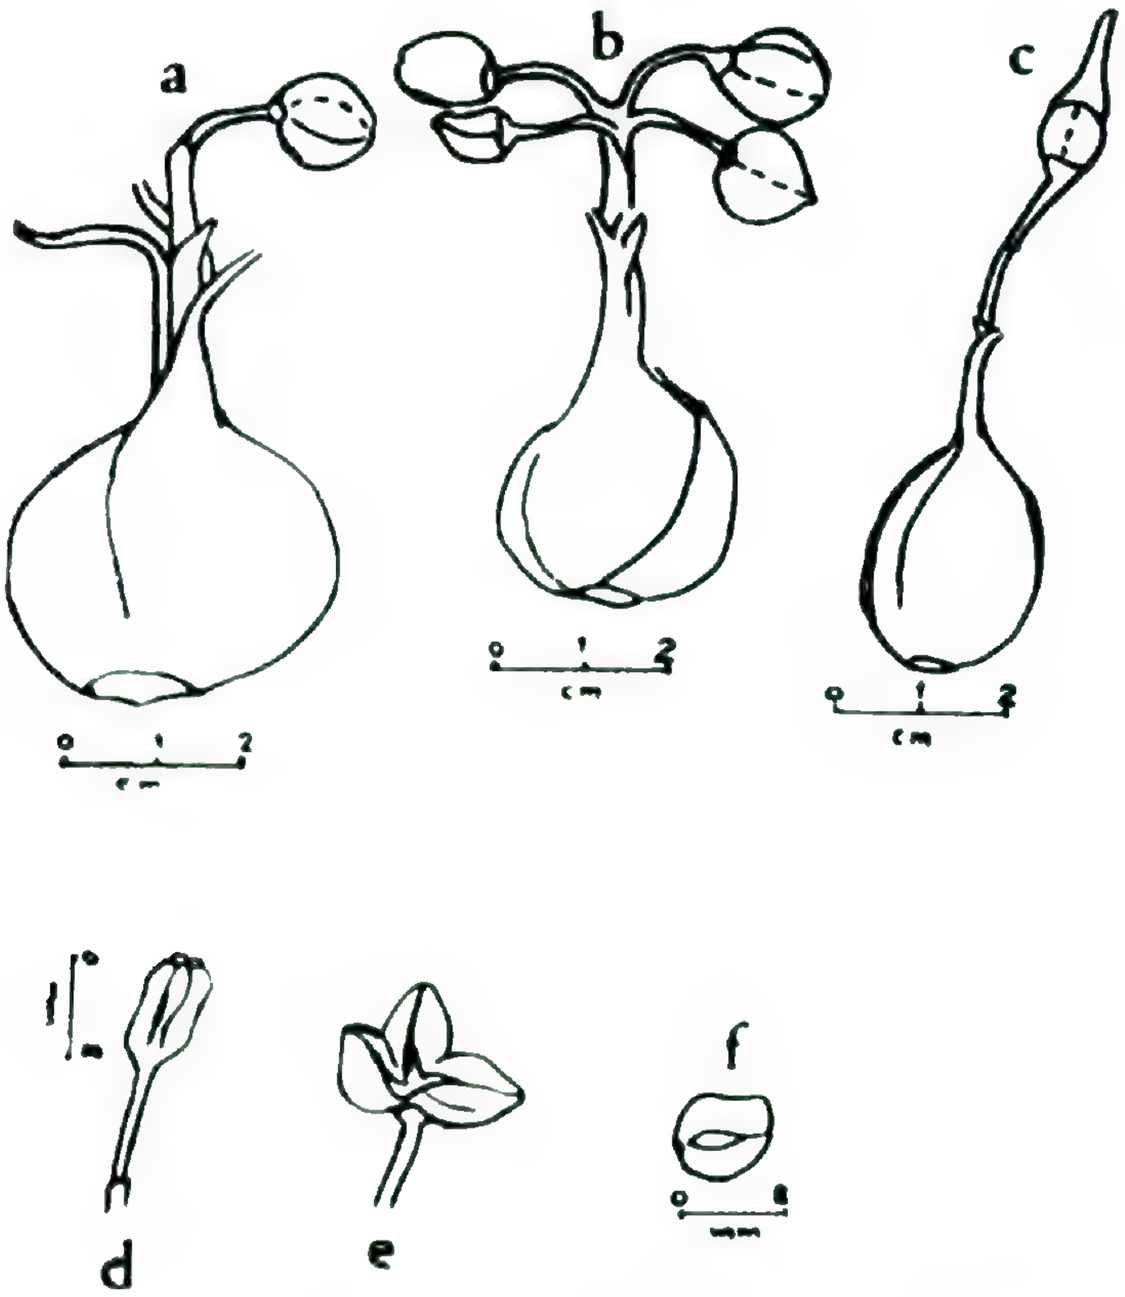

FIGURE 1. Growth habits of *U. nana*.—a, b, c. Fruiting plants of Morphs A, B, and C, respectively.—d. Mature flower before anthesis.—e. Dehisced fruit.—f. Seed.

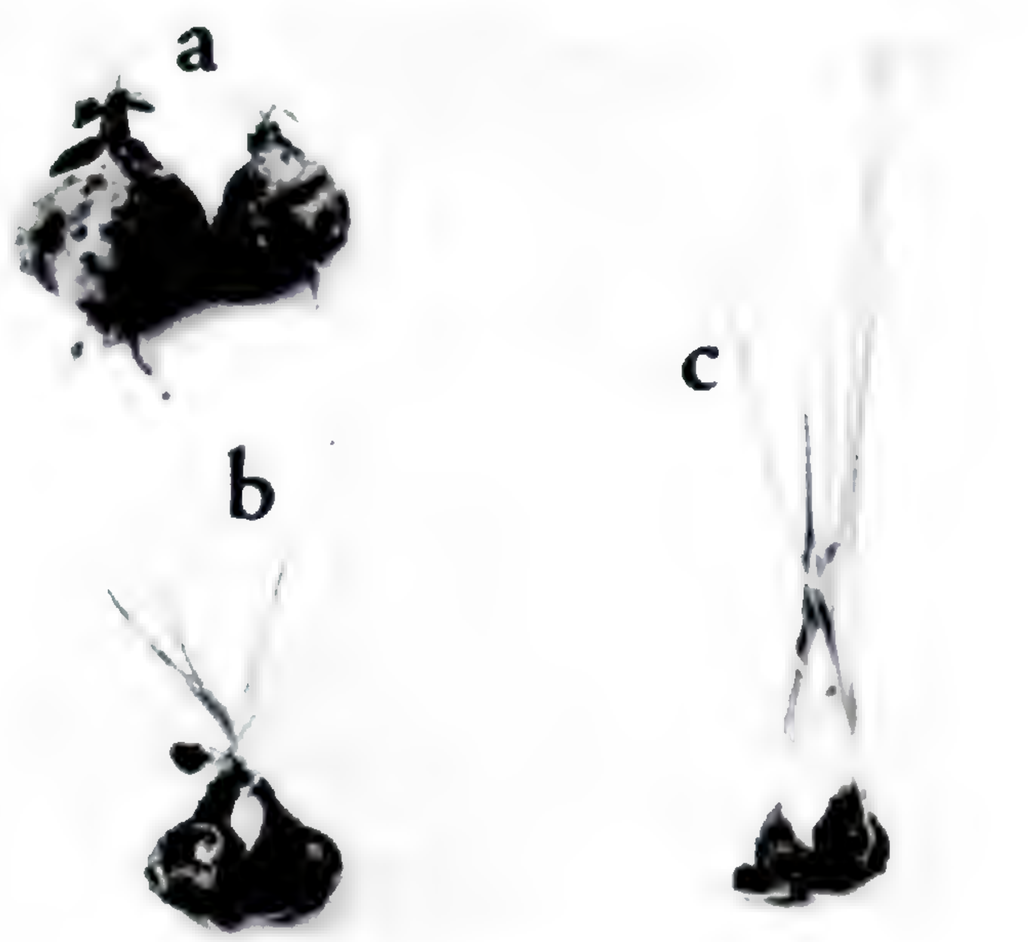

FIGURE 2. Vegetative plants of *U. nana*.—a, b, c from Morphs A, B, and C, respectively.

long as well as in circum.; seeds dark brown to black, 7–8 mm long, 4–6 mm across (including the membranous wing), uniseriate in each loculus.

Paratypes. NIGERIA. ILORIN: about 1.5 km to the northeast of the main buildings of the University of Ilorin, SOO/2121, SOO/2229, SOO/2230, SOO/2231 (IUH, FHI).

These bulbs resemble *U. pauciflora* in being few-flowered, and the depauperate morphs of *U. indica* in having linear-lanceolate, stiffly erect leaves and few-flowered inflorescences. They differ, however, in the form and width of the vegetative leaf, and in the size of the scape and the positioning of the flowers on the inflorescence. Examination of the herbarium specimens at the Herbarium of the Forest Research Institute of Nigeria (FHI), Ibadan, and at the University of Ibadan Herbarium (UIH) revealed that such specimens have not been collected previously in West Tropical Africa. Earlier examination of materials at Kew also showed that specimens of this taxon have not been recorded.

Certain variations were observed in the floral and vegetative morphology, on the basis of which the population was segregated into three morphs designated A, B, and C. This informal categorization was necessary for the purposes of karyotypic examination and eventual cytogenetic studies.

Morph A. Bulbs ovoid-spherical, 3–4 cm diam., 2–3 cm high, usually with relatively short bulb neck. Leaves thin, narrow, coiled (filiform), 10–15 cm long, 1–2 mm broad, dark green, crescent-shaped in transection. Peduncle up to 2.5 cm high outside of the bulb neck, thick and stiffly erect, green, bearing 2–3 flowers terminally. Tepals 8–10 mm long, 2–3 mm broad, yellowish green with hyaline margin.

Morph B. Bulbs ovoid-spherical, 2–3 cm high and diam., with a conspicuous bulb neck as high as 4.5 cm. Leaves thin, narrow, coiled, light green, crescent-shaped in transection, 8–12 cm long, about 1 mm broad. Peduncle stiffly erect, 3–4 cm high outside of the bulb neck, pinkish to purple, usually bearing 3–6 flowers terminally. Tepals pinkish tinted green on the margin, 7–8 mm long and ca. 2 mm broad.

Morph C. Bulbs small, oval-globose, 0.75–1.5 cm diam., 1.5–2.5 cm high, with relatively short bulb neck. Leaves light green, acutely erect, linear-lanceolate with open transcection and shortly apiculate apex, 15–20 cm long, 2–3 mm broad. Peduncle thin, erect but not firm, up to 2.5 cm high outside of the bulb neck, bearing one terminal flower usually. Tepal greenish with hyaline margin, 6–7 mm long, about 1 mm broad.

The floral dimensions of the three morphs overlap so that they are not easily distinguished, but morph C differs distinctly in vegetative morphology. Plants of *U. nana* must have escaped recognition for so long because of their habit of growth: the fruiting shoot is hardly seen above the heap of burnt litter; the inflorescence begins to emerge from the soil less than 36 hours after the first burning. The flower and fruit colors merge with that of the dark brown soil surface once the charred

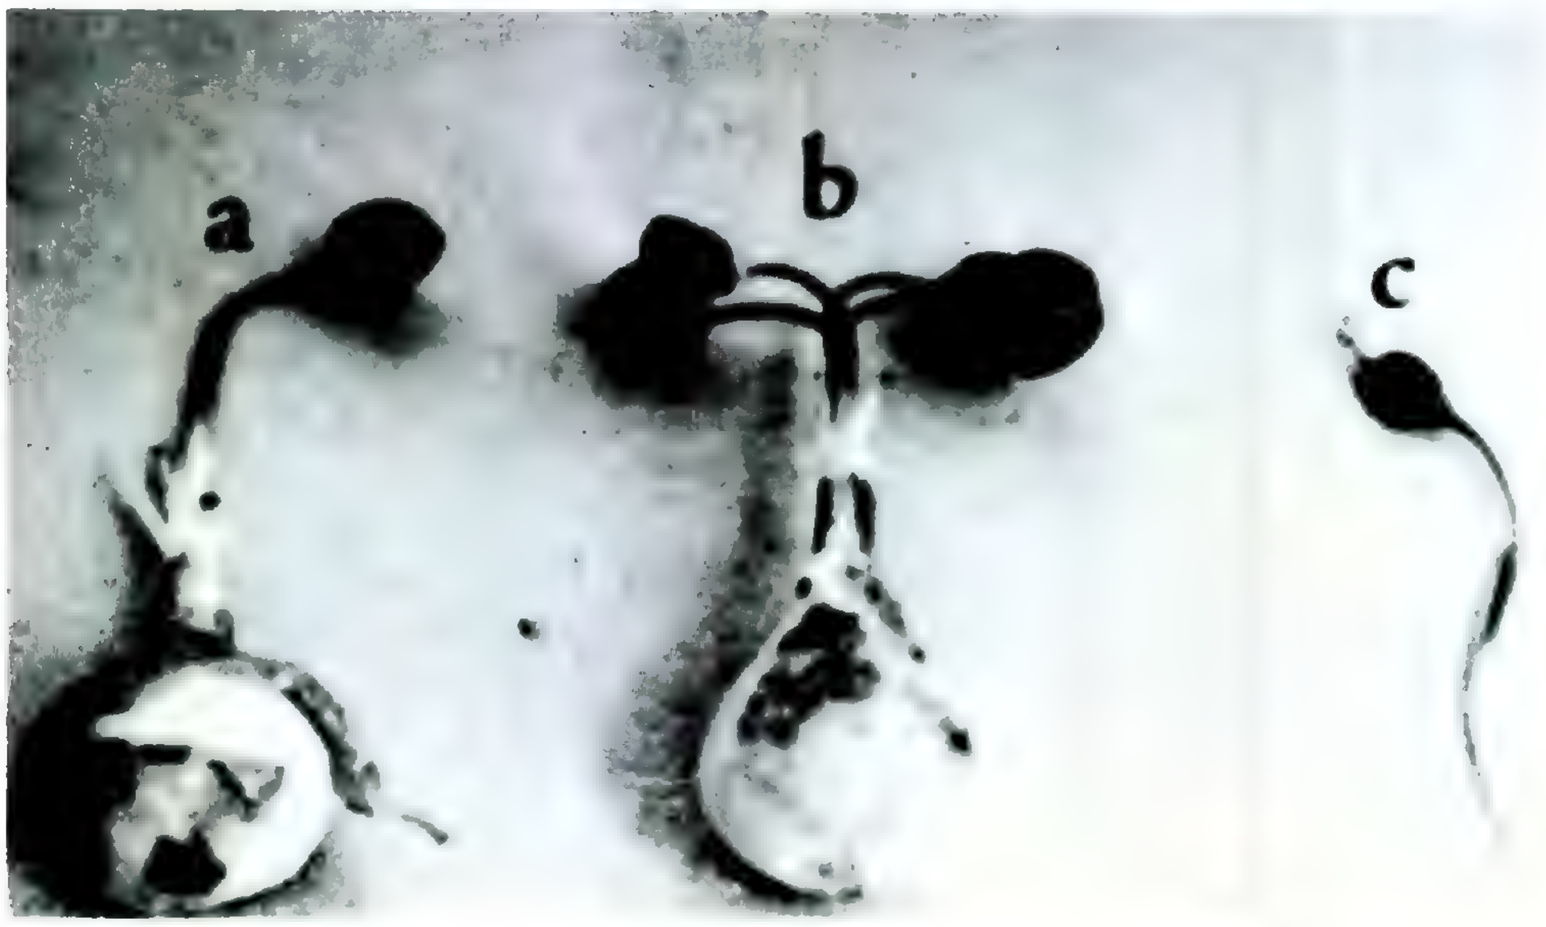

FIGURE 3. Fruiting plants of *U. nana*.—a, b, c from Morphs A, B, and C, respectively.

remains are blown away by the wind, and the vegetative leaves pass easily for the leaves of *Bulbostylis fimbristyloides* and related sedges. The leaves are not evident when the plant flowers but rather are produced when the surrounding vegetation is luxuriant.

Following is a taxonomic key for separating the three morphs and their close relatives within the genus:

1a. Pedicel 3 cm long or longer; inflorescence various in height and number of flowers, but a lax raceme; capsule globose ..... *U. indica*
1b. Pedicel shorter than 2 cm long.
  2a. Scape 6–10 cm tall; inflorescence a raceme of 6–10 flowers; fleshy tunics purplish violet ..... *U. pauciflora*
  2b. Scape less than 5 cm tall; inflorescence of 1–6 flowers borne terminally; fleshy tunics white ..... *U. nana*, morphs A, B & C
    3a. Leaves erect, flat in transection, 15 cm long or longer; inflorescence single-flowered, terminal, or with two flowers, one of which is subterminal ..... *U. nana*, morph C
    3b. Leaves obtusely arching or spreading, coiled, crescent-shaped in transection, up to 12 cm long; inflorescence 2–6-flowered, umbellate.
      4a. Flowers pink, 3–6 per inflorescence ..... *U. nana*, morph B
      4b. Flowers greenish, 2–3 per inflorescence ..... *U. nana*, morph A

DISCUSSION

Urginea is probably of recent origin in West Tropical Africa (Oyewole, 1975), arising probably like its very close relative *Albuca* L. from southern-southeastern Africa and migrating across central Africa into the west (Oyewole, 1971). It is therefore conceivable that, faced with myriads of ecological niches in this region, the number of representative species and infraspecific taxa is likely to be much higher than Hepper (1968) recognized. The distinct morphology of *U. nana*, with its peculiar habitat, sets it apart from previously known species of the genus. However, the existence of different morphs within a seemingly uniform ecological niche suggests that the population of *U. nana* may not entirely represent one genetic system. It is hoped that investigations now in progress on aspects of the biosystematics of this species will resolve this problem before long.

The discovery of *U. nana* in Nigeria underscores the fact that the latest treatment of Liliaceae in West Tropical Africa (Hepper, 1968) is due for revision. It also indicates that *Urginea* may be represented in this subregion by many more taxa than are now known (Oyewole, 1975).

Julian Alfred Steyermark

This issue of the Annals of the Missouri Botanical Garden *is dedicated with respect and admiration to Julian Alfred Steyermark, who began and ended his astoundingly productive life in St. Louis, Missouri. The following set of recollections will help paint a portrait of one of the world's great botanists and plant explorers. A memorial service for Dr. Steyermark was held at the Missouri Botanical Garden, where he passed the final years of his career. The first contribution, by Dr. Peter H. Raven, Director of the Missouri Botanical Garden, is an overview of Dr. Steyermark's life and accomplishments and was presented at the memorial service. Several remembrances generously contributed by Dr. Steyermark's friends and colleagues follow.*

The frontispiece: Julian Steyermark, 1987, Warren County, Missouri.

Julian Alfred Steyermark

Born, 27 January 1909, St. Louis, MO.

Graduated from Soldan High School, St. Louis, MO, 1925.

Married Cora Shoop, 1 September 1937, no children.

B.A., Washington University, St. Louis, MO, 1929.

M.S., Washington University, St. Louis, MO, 1930.

M.A., Harvard University, Cambridge, MA, 1931.

Ph.D., Washington University, Henry Shaw School of Botany, St. Louis, MO, 1933.

Research Assistant to Robert E. Woodson, Jr., Missouri Botanical Garden, 1934–1935.

Biology Instructor, University City Senior High School, University City, MO, 1935–1937.

Taxonomist-Ecologist, U.S. Forest Service, summers 1936–1937.

Assistant Curator, Field Museum of Natural History, Chicago, IL, 1937–1947.

Associate Curator, Field Museum of Natural History, Chicago, IL, 1947–1950.

Curator, Field Museum of Natural History, Chicago, IL, 1950–1958.

Professor of Botany, Southern Illinois University, Carbondale, IL, April–June 1958.

Professor of Botany, University of Missouri, Columbia, MO, June–August 1958.

Botanist, Instituto Botánico, Ministerio de Agricultura y Cría, Caracas, Venezuela, 1959–1984.

Curator, Instituto Botánico, Caracas, Venezuela, 1975–1981.

Curator, Missouri Botanical Garden, St. Louis, MO, 1984–1988.

Died, 15 October 1988, St. Louis, MO.

132,223 is the last number in Julian Steyermark's collecting book. Julian Steyermark described more than 1,000 new species of plants during his career.

New Books from the Missouri Botanical Garden

Thesaurus Draculanum, 1 & 2

Carlyle A. Luer with Rodrigo Escobar R. German translations by Fritz Hamer. Illustrations by Stig Dalström.

Thesaurus Draculanum is a monograph of the genus *Dracula*. Each of the 80-odd known species is illustrated by a watercolor painting accompanied by descriptions, discussions, and distributions in both English and German, with distribution maps and black and white line drawings. In elephant-size format. Standing orders available. The first two of six fascicles. $40.00 each.

The Moraeas of Southern Africa

Peter Goldblatt

Morea is a genus of 119 currently recognized species. The monograph treats those found south of the Zambezi and Cunene Rivers, some 103 species. In addition to the information expected in a rigorous taxonomic monograph, conservation, cultivation, taxonomic history, and floral and pollination biology are treated. Many of the taxa treated are illustrated with full-size, full-color illustrations by Fay Anderson. xi + 224 pp., 64 color plates. National Botanic Gardens, Kirstenbosch, and the Missouri Botanical Garden. ISBN 0-620-09974-7. 1986. $35.00.

Modern Systematic Studies in African Botany

Peter Goldblatt & P. P. Lowry, II, Editors

This monograph contains about 60 papers dealing with systematics, ethnobotany, and conservation, presented at the Eleventh Plenary Meeting of the Association for the Taxonomic Study of the Flora of Tropical Africa held at the Missouri Botanical Garden, St. Louis, on 10–14 June 1985. 710 pp. 1988. $90.00.

To place an order, use this form or a photocopy of it. U.S. shipments: add $1.50 for one book and $.50 for each additional book; non-U.S. shipments: check or money order in U.S. funds, payable to U.S. bank, add $2.50 for one book, and $.50 for each additional book. Orders should be prepaid; a $1.00 fee will be added to orders requiring invoices. No shipments are made until payment is received. Mail form with your check or money order, payable to Missouri Botanical Garden, to:

People were Julian Steyermark's first love, but flowers were his second. He was a passionate man, and some of his passions were shaped by early trips out of a St. Louis that was crowded and smoky into the gentle Missouri countryside, where he and his friends first sought unusual birds. Later he reveled in the autumnal drifts of asters, in enjoying the purple-brown trilliums and delicate orchids of early spring, and in collecting samples from the legions of sedges that he could see only dimly through the torrential cascades of sweat that poured from his brows as he crouched over gravelly riverbars during the torrid Missouri summers. Even the long-exserted anthers of the ribworts that appeared in early summer must have fascinated this unusual young man, who grew in knowledge about the diversity of plants that nurtures all who take the time to stop and appreciate it.

Everywhere he went Julian was recognized for his achievements: the governments of Guatemala, Ecuador, and Venezuela; his alma maters at Washington University and here at the Garden; the Missouri Department of Conservation; and the Sierra Club all soon came to know him as an inspiring and unique individual, and gave him abundantly of their prizes and awards. Everyone knows that Julian collected more plant specimens than anyone else has ever done, an incredible 132,000 specimens, and that he was a prolific writer and herbarium worker. In fact, if we hadn't known him personally, we might think—reading about his accomplishments—that he was some sort of drudge, dreadful, demanding, and uninteresting. Nothing could have been farther from the truth, however; those of us who had the privilege of enjoying his company, whether in the field, listening to his favorite music, or simply exchanging views on some current topic, know far better.

Julian certainly did enjoy hard work, and appreciated all of those wonderful manifestations of recognition that were accorded him for his accomplishments—to be included in the *Guinness Book of World Records* as the world's champion plant collector was for him an absolute delight. In his life, however, he was sustained to a far greater degree by the love of his many friends. Boyhood friends who ranged through the Missouri woods together searching for rare warblers retained the joys of their mutual admiration into the years of maturity. Those who had the privilege of climbing the steep, rocky slopes and breaking through the interlocking branches of the forests of Venezuela with him never forgot the experience, and expressed their deep concern during his final illness. Once you knew Julian, you simply did not forget him.

Returning here to his boyhood home at an age when most have slipped into the relaxation and hazy days of retirement and gentle decline, Julian undertook the preparation of an account of the plants of what is perhaps the least-known part of the world botanically, the interior of Venezuela, where the tepuis and gorges that he loved so deeply make up the spectacular fabric of the fabled Lost World. As he did everywhere he lived and worked, Julian renewed sturdy old friendships, and forged new ones, a process that continued all his life. Bruce and Luther, Gerrit and Jeany, Tamra and Bruno, and so many others—you each gave him much, especially during his final days of great physical discomfort, but you got far more than you gave. Julian's open, happy smile; his sweet, joyous, and dedicated personality; his attentiveness to the task at hand; and his unremitting, dignified friendship will form memories that will be with each of us until our own final days.

For someone who spent his childhood amongst the beauties of bellflowers, gerardias, and desmo-

diums, gumweeds might have seemed a strange choice as the subject of a doctoral dissertation. These sunflower relatives exude a white, sticky sap that fills their unopened flower heads before they expand to reveal the golden-yellow inflorescence hidden within each. Gumweeds are relatively uncommon in Missouri, but range widely over the American West and Mexico. Julian's graduate advisor, Jesse Moore Greenman, who trained an entire generation of American taxonomists here in St. Louis, was determined to complete the great task of John Torrey, George Engelmann, and Asa Gray—to make known the variety and complexity of the plants of our continent, and he assigned doctoral problems accordingly. For this purpose, Dr. Greenman enlisted Julian, who was afire with his love of plants, into his army; and the young man set out along the dirt tracks and across the fields of the West, publishing his work ultimately in the Garden's *Annals*.

For the 28-year-old Julian Steyermark, just married, there followed 21 years in Chicago, where he ultimately became Curator of Botany at the Field Museum. That institution, and his contact with the famous botanist Paul Standley, provided his introduction to the plants of Guatemala and brought home to him just how little we knew about the plants of the American tropics. Missouri's flowers remained his favorites, however, and he cultivated them lovingly, with his wife Cora, in their own wildflower garden near Chicago, a sanctuary now maintained by The Nature Conservancy. For 30 years Cora and Julian crisscrossed Missouri searching for plants, driving thousands of miles back and forth from their home, camping in riverbottoms, by dusty roadsides, or in forests, so that they would come to know more fully the detailed distributions and characteristics of the plants of this state. Their cultivation of many of these plants in their home garden was not merely a scholarly exercise; it was also an act of love, a celebration of their natural beauty and their individual character, as anyone who has turned the pages of Julian's exemplary 1963 *Flora of Missouri* will know. What memories those explorations provided Julian and Cora, and what times they shared together! To know about some of them, read Cora's *Behind the Scenes*, a testimony to the beauties of our state and the joy that is in store for those who take the time to appreciate, understand, and enjoy them. Cora wrote:

> The morning was cold and clear. Pine trees and shrubs, gray and bent with ice and snow, lent variety to the icicled oaks. At the top of the hill we came upon the sunrise. The whole view for miles across the hills was a brilliant blaze of crystalline purity. Against the sun, the tops of trees turned to polished gold, shading to silvered lower limbs rising above a soft setting of snow-covered shrubs.
>
> Julian stopped the car. "I'm stuck with a view," he said. "I'm afraid I'll break something if I move."
>
> "That whole view looks as if it might break if you breathed on it. This is something you see once in a lifetime. I'm glad we stalled last night," I said and really meant it.

From Chicago, Cora and Julian moved on to Caracas, where they traded goldseal, gentians, and puccoon for *Brocchinia*, *Chimantaea*, *Sterigmapetalum*, and *Heliamphora*. The exchange proved a rewarding one, and Julian went on to add more to our knowledge of the plants of Venezuela than anyone had before. A quarter of a century was enough—filled with friends from Venezuela, new friends from the States, wonderful new plants, many of them extravagantly beautiful, and hundreds named in Julian's honor, hundreds of them. After Cora's death, Julian came back here to his hometown and began to write in earnest about the incredible plants of the Lost World. His last work will be completed here, and will stand as a final testament to his industry and to his scholarship. As for any human being, however, what will prove to be even more important to all of us will be our memories, for Julian Steyermark was an inspirational person, one who projected his own values without trumpeting them, and thereby enriched all our lives, as he did the literature of botany.

In concluding her book, Cora wrote:

> It was a long exploration of more than 30 years from which we have related merely a few experiences representing each month of the collecting season. So we see—a book is not only written and rewritten, it is lived through a life of sweat, privations, and joys behind the scenes, before the final word is ever put on paper.
>
> We, X.Y. [that was her affectionate term for Julian in the book] and I, hereby will the state to the next botanist.

Is that not a reflection worthy of us here today? We all toil in a common field, inspired by early memories, contributing to knowledge, doing what we can for one another and regretting what we cannot do. In the plants that support and nurture us, enrich our souls with their beauty, and inspire our actions, we have found a common bond. Here today we have found another: the remarkable and full life of a truly luminous human being, our friend Julian Steyermark, whose fellowship we enjoyed so deeply, and whose life we will remember with gratitude.—*Peter H. Raven, Director, Missouri Botanical Garden; from Julian Steyermark's memorial service.*

During the 1940s in my beginnings as a botanist, I started to understand the importance of Dr. Julian Steyermark's works on the taxonomy of the Venezuelan flora. The National Herbarium already possessed numerous collections made by the remarkable scientist. By the 1950s, our friendship had grown stronger and lasted for more than 30 years. His long and exhaustive research of the Venezuelan geography created a major collection that has contributed in a decisive way to enhance Venezuela's floristic inventory.

His humility and generosity were the most outstanding features of his personality. A few years ago, before departing for Venezuela's Guayana, I asked Julian to inform me on the area I was going to visit, a place he knew and had explored. Among the helpful and valuable facts he supplied was the name of a man who knew the region well and could act as a "baqueano" [guide]. Arriving in the area, I found the person Julian had mentioned. I told him my mission in the area and that Dr. Steyermark had recommended him to me. To my suprise he answered, "Dr. Steyermark? I have never heard such a name." However, I insisted and slowly repeated, "Are you sure you don't know Dr. Julian Steyermark?" His facial expression suddenly changed and he replied smiling, "Oh! you mean Julián, of course I know him and I am ready to help you."

This story helps to illustrate Julian's sense of humility, generosity, and harmony. His legacy as a scientist goes hand in hand with the personal attributes that made him a great human being and a beloved friend to those who knew him.—*Leandro Aristeguieta, Universidad Central de Venezuela, Jardín Botánico de Caracas.*

FIGURE 1. *Fuchsia steyermarkii*, from cloud forest in southern Ecuador.

When I arrived at the Instituto Botánico in Caracas in the summer of 1975 looking for a project to help me learn about tropical plants, I was brought into the office of one very busy, grumpy Dr. Julian Steyermark. Faced with a botanical neophyte, he suggested that I begin collecting plants from the hills surrounding the Instituto—a patch of secondary, deciduous forest in the heart of the city. Years later this project led to a paper we published together on the vegetation of the deciduous forests of Caracas, but only after many journeys in each other's company to the few wooded areas near the city not yet overtaken by apartment buildings or "ranchos." Following up our finding of five species of the coca genus, *Erythroxylum*, growing side by side in the hills above the Botanical Garden, a student of mine at Simón Bolívar University in Caracas completed a wonderful thesis on the comparative reproductive biology of the group. Another result of our study was the recognition of two species new to science, *Eugenia mcvaughii* and *Erythroxylum undulatum*, both based on plants found less than 100 meters from the front door of the Instituto. It was the shortest trip I know of for specimens to be placed in the type collection of the National Herbarium.

Now years later I sit in Julian's former office—sometimes in his chair, picking up where he had left his unfinished project, the *Flora of the Venezuelan Guayana*, more affectionately known as the "Flora of the Lost World." Julian was a "baqueano" (guide, in Venezuela) to me, for he opened up many paths that I was to follow.

My botanical tribute to Julian was the naming of *Fuchsia steyermarkii*. Just after his death, I was to return to the original site where the plant was found, in lush cloud forest on the steep slopes south of the Nudo de Sabanilla, in southernmost

Ecuador. I got there in a rented taxi, a few hours by car from the city of Loja; he got there by foot and mule, on a fortnight trek through endless rains, in October of 1943. His *Fuchsia* is a most unusual species, with needlelike leaves, and if it survives in cultivation it will be highly esteemed.

Many simple folk all over Venezuela knew and remembered Julian. I met some of them, usually in remote places, like "Horacio," a Makiritare Indian who spoke no Spanish but had climbed many a tree for him; and José Mendoza, an Andean homesteader from San Vicente de la Revancha, whose senile father had guided Julian years ago far into the páramos towering over the valley. Both reacted similarly when I mentioned Julian's name: a big, amused grin accompanied by signs of respect for a man so dedicated to his botanical mission.—*Paul E. Berry, Missouri Botanical Garden.*

I had been at the New York Botanical Garden as a doctoral student for all of three weeks in 1980 when I first met Julian Steyermark. He was visiting the New York Botanical Garden to consult our Guayana Highland collections and to collaborate with Bassett Maguire on several taxonomic treatments. Of course, I already knew of him by reputation. I was a novice to tropical botany, so in an attempt to say something intelligent to him I dug back into my M.S. thesis on *Isoëtes* and located the citation of *Steyermark 85179*, which I had identified as *I. melanopoda* Gay & Dur. I reported this to Julian, and to my amazement he immediately told me where in Missouri the specimen had come from and the month during which he collected it 23 years previously! This was not to be the last time over the following eight years years that Julian's prodigious memory would impress me.

I also became aware of Julian's capacity for work as I observed him during his subsequent periodic visits to New York. Occasionally, he would share my office because of our mutual interests in the Guayana Highland flora. He stayed in the Garden's Snuff Mill apartment during his visits. By 7:30 A.M. he would be at the herbarium. With a single-mindedness he worked on specimens until about 6:00 P.M. with only a half-hour break at the lunch table. Julian was not one for idle chat, and he clearly did not like to be disturbed while working. At six, and also with a single-mindedness, he would round up any remaining staff and students and go have a huge dinner, followed always by a stop at the local ice cream establishment. Occasionally, he would take in a movie, but more often than not he would head back to the herbarium for several more hours of work before retiring for the night.

And thus, day after day, he would make his way through huge piles of specimens, writing descriptions of new taxa on the spot in his nearly illegible scrawl. Julian confessed that he "over-described" occasionally, and that perhaps he split excessively. However, he justified it by saying that he viewed his role as one of describing biotic diversity as he saw it. He would leave it to following generations of botanists to determine just how "good" his decisions were. How history will judge his taxonomic decisions does remain to be seen, but there can be no doubt that Julian had an excellent "eye" for seeing differences. I also know that I trust his specimen annotations more than those by just about anybody else. During the first half of this century, when a researcher needed quick, reliable determinations for neotropical specimens, the solution was "send them to Standley." Julian was heir to this role. His magnum opus, *Flora of the Venezuelan Guayana*, will aptly attest to his unparalleled knowledge of the neotropical flora. In an age of few heroes, Julian was one for many of us.—*Brian M. Boom, The New York Botanical Garden.*

Hace cuatro años, el 7 de junio de 1984, tuve el honor de darle con alegría y en nombre de los botánicos de Venezuela, un adiós, un hasta luego, a Julian Steyermark. Esta despedida era transitoria, ya que por su propia decisión, volvía a su tierra natal, Saint Louis, Missouri. A pesar de su ida, Julian no podía resistir la tentación de permanecer mucho tiempo allá, solo en el norte, razón por la cual, con frecuencia hasta principios de este año, regresaba a Venezuela, pues como el decía: "amor a primera vista," fue su reacción al ver por vez primera a este país en 1943. Y, cual enamorado, exclamó: "Mi amor a Venezuela, se debe no solo a sus flores, a su fauna, a sus paisajes, sino también a mis amigos quienes poseen una alta sensibilidad, capacidad, y deseo de trabajar en la botánica y en la conservación de sus recursos naturales. Por eso mi amor por Venezuela fue instantáneo."

Julian Steyermark, nació en Saint Louis, Missouri, el 27 de enero de 1909. Desde muy temprana edad sintió el reto de conocer la naturaleza que lo rodeaba. Allá por el año de 1925, cuando era *Boy Scout* en su ciudad natal, se interesó en la zoología, fijando primeramente su atención en las aves. En ese mismo año ingresa al club de Biología de su colegio y su espíritu naturalista se concentró en el fascinante mundo de las plantas. Desde entonces, sólo vivió en función de ellas. Combinando sus estudios con sus labores de Guía Naturalista en los parques de Saint Louis y sus

FIGURE 2. Julian Steyermark (lower right) at ca. age 20 as counselor at summer camp in Maine.

alrededores, fue formando una buena colección de plantas la cual fue adquirida por el Herbario de Missouri en 1934 por 84 dólares. Este dinero fue la base para comprar su primer vehículo, para poder continuar con mayor facilidad sus trabajos botánicos.

Julian llegó a Venezuela en diciembre de 1943, cuando en misión del gobierno de su patria de origen, vino a buscar la corteza del árbol de la quina, indispensable durante la Segunda Guerra Mundial para combatir el paludismo. Sus primeras incursiones botáncas en el país las efectuó en lo que es hoy el Parque Nacional El Avila, de allí pasó al Oriente de nuestro territorio, regresando a Estados Unidos en 1945 con una colección de 8,000 muestras botánicas.

La belleza escénica de los diferentes ambientes venezolanos, el contacto con las plantas, coló tan hondo en la sencilla humanidad de Julian, que soñaba que Venezuela debería ser su país. Este sueño, cual regalo de navidad, se convirtió en realidad cuando en diciembre de 1959 recibió la invitación de Tobias Lasser, por recomendación de William H. Phelps, para que formara parte del personal del Herbario Nacional de Venezuela, donde permaneció activamente como estudioso de la flora Venezolana. Por su larga trayectoria y aportes al conocimiento florístico del país recibió entre otras las siguientes distinciones: Orden Andrés Bello (1974); Orden al Mérito en el Trabajo, Primera Clase (1974); Orden Henri Pittier (1979); Premio William H. Phelps, otorgado por la Sociedad Venezolana de Ciencias Naturales; Miembro Correspondiente Nacional de la Sociedad de Ciencias Naturales de la Salle; Miembro Titular de la Fundación Terramar; Investigador Emeritus del Jardín Botánico de Caracas, INPARQUES (1986).

Julian Steyermark, después de sesenta y nueve años de búsqueda y trabajo activo en su mayor obra botánica, *Flora of the Venezuelan Guayana*, murió en Saint Louis, Missouri U.S.A, el 15 de octubre de 1988. Por eso hoy siento la necesidad de darle en nombre del personal del Jardín Botánico de Caracas un adiós lastimoso, con dolor y nostalgia.

En este momento recuerdo, que un día en febrero de 1984 Julian me dijo, sentado en la cima del Aratitiyope (Templo Sagrado de Las Guacamayas), Territorio Federal Amazonas, en un momento de descanso y contemplando la majestuosidad reflexiva del paisaje, "Francisco mi mayor deseo es emplear todas mis fuerzas y mi dinero, para seguir explorando este maravilloso país. También, quisiera que al morir, me enterraran en un tepuy." Julian, si bien es cierto, que tu cuerpo no descansará en la arenisca de los tepuyes, tu imagen caracterizada por el pañuelo rojo, con el cual cubría tu cabeza, quedará guardada en estas mesetas y en la memoria de todos los que salimos al campo contigo. Tú estarás presente en cada planta del tepuy, pues quién de nosotros no se reirá de tus ocurrencias cuando nos topemos por ejemplo con una *Steyerbromelia* de Marahuaca; o cuando saboreemos una base foliar tierna de una Rapateaceae,

bien sea del Roraima, Auyantepuy, Chimantá, o Huachamacari.—*Francisco Delascio Chitty, Director, Jardín Botánico de Caracas, Herbario Nacional de Venezuela; de la Memoria del IX Congreso Venezolano de Botánica, 13–18 Nov. 1988.*

I first met Julian Steyermark 60 years ago. He was painting an orchid in the old Floral Display House of the Missouri Botanical Garden during the annual orchid show. At that time he was an undergraduate student at Washington University.

Later Julian became chairman of the botany group of the Webster Groves Nature Study Society. He wrote articles for *Nature Notes*, which is the monthly publication of the society. He also spoke at the meetings and led botany group field trips to local areas.

Since Julian didn't have the use of an automobile while he was a student at Washington University, he depended on his friends to take him to areas that he couldn't reach by streetcars or trains. He and I went on a field trip to northwestern Missouri to the loess mounds of Atchison and Holt counties during the Labor Day weekend in 1932. This area contains plants that are found only in this part of Missouri. We located most of these species, and Julian took specimens of them for the Missouri Botanical Garden herbarium.

On several occasions Julian and I took streetcars to South Broadway and found many introduced plants along the railroad tracks near the Mississippi River. Some of these plants were very seldom found elsewhere in our area. On the way home from these streetcar trips, Julian identified plants in vacant lots along the city streets.

On one of our field trips to the Ozarks Julian saw a sedge that he wanted to reach on the other side of a stream. We walked through the shoulder-deep water to reach the sedge. He climbed the steepest slopes and descended into the deepest valleys in his search for plants. Julian never seemed to tire, and if he was tired, he continued on anyway.

One of Julian's favorite places was Pickle Springs, where many rare plants were found. This area is now Pickle Springs Natural Area. Another favorite area was near the Meramec River at Pacific, Missouri. This area, which also contains many rare plants, is now known as Pacific Palisades.

Although Julian was so dedicated to collecting

and identifying plants, he did take some time off to play tennis at Tower Grove Park. Also he attended some of the Webster Groves Nature Study Society's parties.

On the day that Julian received his Ph.D. degree from the Henry Shaw School of Botany of Washington University in 1933, I happened to meet him with his parents at the Missouri Botanical Garden. He couldn't stay away from the garden that meant so much to him, even on his graduation day.—*Arthur Christ, St. Louis, Missouri; from Julian Steyermark's memorial service.*

I am very sad with the passing of Julian, a taxonomist extraordinaire and a dear personal friend. I feel very privileged to have known him closely during the last two decades of his life. Julian was truly one of the greats in his field and his contributions to taxonomy, exploration, collecting, and conservation will long be remembered and recognized—and used.

Of all the people I have known personally, he, perhaps as well as anyone, exemplified a person of whom it can be said without any exaggeration that his vocation was also his avocation. I will, above all else, remember him as a person totally devoted to his work and one for whom his work held a never-ending fascination.

I would like to recall several personal experiences and incidents that illustrate some aspects of his personality and career.

I first got to know Julian personally in 1971, when as a graduate student I went to Venezuela to study and collect plants for my thesis. I was already well aware of his many accomplishments and his international reputation. As with almost any other novice going to a foreign country to collect, I was having difficulties in making the necessary arrangements. With some trepidation, I asked for his help, and I was very grateful that he took time to arrange contacts that made my work much easier.

I later learned that he guarded his time very jealously, surely a necessity for someone who received little secretarial help at the time, who published thousands of pages, and who was unrivaled as a plant collector. However, if you were serious about plant collecting, he would often try to help. He was very well aware that the next 20 or 30 years might be the last chance for any of us to study and collect the undisturbed vegetation in many areas of Venezuela that had never been botanically surveyed, and he always felt only a small portion of the country had been adequately surveyed.

After I joined the Missouri Botanical Garden in 1972, a number of other staff members, including Tom Croat and Al Gentry, collected in Venezuela, and we seemed to pass muster as plant collectors since Julian proposed in 1975 that the Garden and the Instituto Botánico organize a cooperative program of joint expeditions to areas in which the vegetation was being severely damaged.

After we secured funds for this work, Julian and I made a number of field trips together, and it was then that I really got to know him well.

Julian was a very goal-oriented person who doggedly pursued his objectives until they were accomplished, whether it concerned writing the *Flora of Missouri* during his free time or whether it concerned collecting plants from a tepui never before explored.

When he went to the Field Museum in 1937, he had already collected over 25,000 plants. There he worked under and was greatly influenced by another of the great plant collectors, Paul Standley, who was to collect well over 100,000 numbers by the end of his own career. Julian early on, as he told me early during our association, determined in his own mind that he would eventually surpass Standley's numbers, and he did.

Even on a daily basis, he—as had Standley before him—would set a goal of a certain number of collections to be made that day, and he would challenge his companions to do the same. He would invariably have a very precise recall of what he collected each day, and he loved to challenge you to guess the totals gained by each person, spicing the proceedings by betting a milkshake on who could guess the closest. I soon learned to keep closer track of what I was collecting!

Although Julian was a modest person who lived a quiet, simple life, he, like all of us, appreciated recognition. After several years of working together, I knew that he was proud of the large number of plants he had collected, and I began to think of ways in which this collecting record might become more widely recognized.

I finally hit upon the idea of nominating him as a champion plant collector to the *Guinness Book of World Records*. Because I was a bit uneasy that he might consider this a trivialization of his accomplishments, I checked out the idea with him beforehand, and he approved. Unfortunately, it took the editors of *Guinness* several years to decide what plant collecting was all about and whether it really had a place in their book. In the meantime, Julian would ask me every time I came to Venezuela what had happened to this proposal, and I had to tell him to be patient, that it was still in the

works. The record was finally included in the 1986 edition, and Julian seemed to enjoy the additional attention it brought him from the popular media.

I earlier mentioned that I'll always remember Julian as a person totally devoted to his work. This perception comes from watching him put in long hours of fiercely concentrated work each day, seven days per week, and 52 weeks per year, but it was also brought home to me in a much more amusing way on our first trip together in 1978.

Our objective on that trip was to collect in a small range of mountains known as the Cerros de Bachiller in the Coastal Cordillera of northern Venezuela, where new agricultural developments seemed certain to destroy much of the virgin vegetation in the near future. Close to a small mountain stream at the foot of the mountains, we had constructed a nice base camp, from which we collected every day. As was customary, we slept in hammocks strung beneath a plastic sheet to keep out the rain. Julian would always wake just before dawn, and as we were getting ready for the day's collecting, he would tell me his dreams of the night before. Every morning during the two weeks of that trip, the dream he recalled would be enjoyable and botanical. Their setting would often be in the "Lost World," and he would discover the most amazing new plants, which often combined bizarre characters from several families, so that he would be very puzzled and strongly challenged on how to interpret these strange plants. After a couple of days of this, I began to think to myself, here is an even more devoted man than I had realized, not only does he devote most of his working hours to botany, but even his sleeping hours are devoted to it.

So these are some of the ways I'll always remember Julian, a valued friend, a man of great accomplishments, a man truly devoted to the good things of this world, and one who leaves an enormous legacy to us all.—*Gerrit Davidse, Missouri Botanical Garden; from Julian Steyermark's memorial service.*

Omnia fluerit. Everything flows. Fifty-five years ago Julian Steyermark, then 24, and taking his Ph.D. here, wrote to me in the spring of 1933—I was at UCLA at the time—asking for the loan of *Grindelia* collections that I had made, gumweeds of the Compositae (as we called them then). On June 21st he wrote again, that the loan was being returned and added that he was tending a ¾-acre plot of grindelias, and rushing his getting a Ph.D. He wrote, "I shall be starting off soon on a 2 or 3 weeks botanical expedition into unexplored parts botanically of Missouri, getting into many remote sections." Some readers may wonder when Julian really began botanizing: on October 13th, 1930, he collected *Grindelia lanceolata* along the railroad tracks bordering the Washington University campus. That collection was numbered *1506*. By September 11, 1932 he had numbered to *7164*, or 5,658 field numbers in less than two years.

Now and then I encountered Julian at the Gray Herbarium or the New York Botanical Garden. Then, with deep pleasure, I came here in 1986 to work in the library, as Julian before me had come to forage in the *hortus siccus*, the dry garden. In researching the vismias and the shrubby gentians, I came to know Julian's detailed collections and his keen interest in plant geography and those "unexplored parts botanically" of Venezuela. By their specimens you shall know them!—so true of botanists. Let me return to Julian's letter of 1933: "One derives the chief or almost the chief pleasure from studying plants in their natural habitat, exploring for them in remote places which add to the zest and thrill of discovery. At least I have always felt that way and most field naturalists hold similar opinions." The tepuis used to be called the "Lost World" but that was before Julian. *Omnia fleurit.—Joseph Ewan, Missouri Botanical Garden; from Julian Steyermark's memorial service.*

My introduction to Julian Steyermark was through the *Flora of Guatemala* while working as a Peace Corps volunteer in Honduras on a floristic survey of one of the central valleys. Honduras does not have any written flora, so the next best thing was the *Flora of Guatemala* of which many volumes were written by Standley and Steyermark. Filled with useful information, excellent keys, and descriptions, it taught me a great deal about tropical botany. When I was finally preparing to leave Honduras with some of my more interesting collections, I was directed here to the Missouri Botanical Garden as the best place to have them identified.

When I finally made it here some months later and luckily was able to get a job, I was told that Julian Steyermark had just come up from Venezuela and was on the staff! One of the first things that I wanted to do was meet him, and you can imagine my surprise and pleasure upon learning that I was going to be working for him, and how much even more surprised I was when three months later I was in Venezuela on a major expedition to the Lost World!

It was a real thrill and a tremendous learning experience to work in the field with Julian. He had

FIGURE 4. Field trip, 1929–1930. Left to right: Charles Leo Hitchcock, Caroline Allen, Julian Steyermark, Josephine Darlington, Mildred Mathias, Dorothy Francis, George Goodman. Photo contributed by Mildred Mathias.

an "eagle eye" for spotting plants and if you didn't see something that he did, he would let you know it. When I first went out on my own to collect some specimens I found a beautiful plant that I thought was very unusual; it had large bright red bracts surrounding a dense cluster of flowers. When I returned to camp, I pulled it out of my collecting bag with pride to show him. But when he saw it, he took it from me in disgust and threw it to the ground, saying sternly "this is *Psychotria poeppigiana* subsp. *barcellana*, one of the most common and weedy plants of South America, don't ever collect it again." I was a little bit embarrassed, so the next day I made even more of an effort and risked my neck to get up on some difficult sandstone bluffs. When I got back to camp, I sheepishly pulled another member of the same family out of the bag to show him. This time, however, he looked at it with a great deal more interest, a puzzled look came over his face, and he admitted that he didn't know what it was, and that it was very likely something new. From then on I learned that whenever he gave that look at a plant, it meant something interesting had turned up. In this particular case it was a genus of the coffee family new for science.

Fieldwork was very special for Julian—rather than "vacations," he went on field trips. It was impossible not to be caught up by his enthusiasm for collecting plants. He always likened collecting to a "treasure hunt." Even with his two artificial hips, he would plow through brush, crawl over and under logs, fall down, laugh about it, and push on. He truly liked collecting all kinds of plants, but I think that the Bromeliaceae were his favorite family.

Julian was involved in the first helicopter expedition in Venezuela, which took place in 1967 to the isolated Cerro Jaua. He quickly realized the advantages of that mode of transportation and found that it would increase even his amazing productivity. He would use it frequently in the following years to get to some of the most inaccessible of the Lost World summits. To think that in all the years prior, when he made so many of his famous expeditions to some of the most remote areas in the country, that everything was by foot, including long and hazardous climbs to the tops of several of the more prominent tepuis, such as Chimantá and Auyan-tepui. Once I understood the complexities involved in these huge expeditions back then, my admiration for him increased even more.

He was a great friend to the Indians of the region. They enjoyed his sense of humor and spirit of adventure. He is somewhat famous in certain Indian tribes. Two years ago, when we were planning a trip to a series of unexplored mountains in the heart of the Lost World, we were surprised to be met by the son and grandsons of an Indian who had worked with Julian back in the 1940s. They

had heard that "Hulian Esteyermark" was to be back in the area, and were eager to volunteer their help.

On a personal side, it took a while to get to know him, and he did have some unusual ways.

—I thought that he was kidding when he told me about his liking for rock & roll music until he showed me his more than 800 records ranging from Elvis Presley to the Rolling Stones. He also loved Venezuelan and Andean folk music.

—He loved to bet milkshakes on whether his friends could identify a plant or not. I paid out my fair share to him and to Ron Liesner (an expert at plant family identifications).

—He would eat sparingly for breakfast or lunch, but there were few who could match him at the dinner table. Buffets at nice restaurants were his favorite, and he would go back time after time before he was ready for dessert.

—Other than fancy buffets, he thrived on fruits, vegetables, and ice cream and was a great experimenter with native edibles. Flower fragrances were irresistible to him; we would have contests in the field to see who could find the most fragrant flower, and he smelled every one with great pleasure.

—Swimming was a favorite pastime of his. The only time that he would take off from the herbarium or field (or let any of his assistants do so) was to go to the beach. He loved floating in the waves and would do so for hours at a time.

Julian was a most ardent and effective conservationist. He worked hard in Venezuela through the National Park Service to protect the forests in the North that were, and still are, rapidly being destroyed, and was instrumental in identifying many areas in the South worthy of protection. In late 1988, we were told that the President of Venezuela was signing into legislation a new National Park in the delta of the Orinoco River. It was planned with Julian's help.

Finally, I would like to share some parts of a letter that was sent to Julian a few weeks ago that illustrates his impact upon others around him, not just as a botanist, but as a person who could inspire others:

> I was a student of your Biology Class at University City High School during the *1937–38* period at the time just prior to your leaving for the Field Museum in Chicago. My memories of you are very strong and positive as a teacher and as a person. You provided a great role model for a youngster interested in science. And I remember how impressed I was with the fact that *my teacher* was leaving to become Curator of a portion of the famous Field Museum. You and several of the other faculty members at U. City High provided great inspiration to accomplish at that point in my life. Thanks.

Fifty years later, another student of his feels the same way.

I am deeply saddened to lose a great friend and a teacher. I will never forget him and what he has done for botany, for conservation, and for me.—*Bruce K. Holst, Missouri Botanical Garden; from Julian Steyermark's memorial service.*

The expression on his face was rather eloquent when Julian saw the pile of newspapers that I had put in front of him on his desk. He knew that I was an ecologist starting to do research in the cloud forests of Rancho Grande, in National Park Henri Pittier some 100 km west of Caracas. My "botanical collections" consisted mainly of large, unlabeled leaves pressed between five or even ten sheets of newspaper in order to assure their drying. "What am I supposed to do with this?" Julian asked me impatiently. "Well, I think that you can identify them," I answered a little bit scared. After a few silent minutes, during which Julian glanced through the "specimens," he returned the pile to me and said, shaking his head, "These specimens are unidentifiable, they are all sterile; there is nothing I can do with them." And with these words he continued typing labels on his old OLIVETTI typewriter, and I suspected that I had done something wrong.

After this episode, which occurred sometime in early 1974 in Julian's office at the Instituto Botánico in Caracas, I realized that plant collecting in a tropical cloud forest was rather different from what I had done before on a very limited scale in the Mediterranean macchia of southern Italy or the island of Sardinia. Under Dr. Steyermark's guidance I learned how to make proper plant collections and how to identify them to family, genus, or even species. I soon realized, too, how fortunate I was to have such an outstanding teacher: every passing day I was increasingly impressed by the astonishing taxonomic knowledge of this man, who seemed to be omniscient and blessed with a remarkable memory of the most complicated plant names!

After having been invited to my first chili con carne at Julian's home (his favorite dish expertly prepared by his wife Cora), our relationship strengthened, partly because in the meantime I had improved the quality of my botanical specimens. A couple of years later, we engaged in a joint venture, resulting in the publication of the

Flora del Avila. Julian wrote most of the keys of that book at home while recovering from his two hip operations and while I was in Austria concluding my Ph.D. thesis. At my return to Venezuela in September 1976, we then had a rather hard time finishing the rest of the manuscript (some 1,600 pages), since my Tyrolean stubbornness was not less persistent than Julian's Missouri stubbornness! This book, however, constituted a tremendous experience for me, and since then we had become colleagues, working together very closely in the Instituto Botánico. From then on, Julian was always anxious to be the first to see my collections from the Venezuelan Amazonas and later from the many tepuis of the Guayana Highlands.

In 1982 we decided to start another new project titled *Flora and Vegetation of the Venezuelan Guayana*. We realized that such an enterprise would take years of most intensive work, but we both decided to dedicate all our efforts and resources to that project. Although destiny later divided our paths, Julian and his collaborators have advanced relentlessly towards completion of that flora, whereas I have continued to contribute by collecting interesting plants from the many places visited during my ecological and phytogeographical fieldwork in that region.

It was a great satisfaction for me to invite Julian to an expedition into the Chimantá massif, one of the richest Guayana mountains, where he and John Wurdack had done such pioneering botanical exploration in 1953 and 1958. When we established camp near a huge colony of *Chimantaea mirabilis*, a most striking member of the Compositae discovered by him in 1953, Julian could not hide the emotion caused by this reencounter after 25 years! And then, there he was, the "classic" Julian Steyermark, sitting at his camping table describing and pressing plants . . . and plants . . . and plants, amazingly numerous plants every night (at that time he was at his number 128,000). And every two minutes he would call me and exhibit another exciting find, or explain another variation or another novelty. One year later we would be again on the same mountain and discover a new genus (*Acopanea* in the Theaceae), and then get flooded at our camp at 2 o'clock in the morning with icy water half a meter deep from the nearby caño!

Julian Alfred Steyermark, the great botanical explorer of the Guayana and many other places of the Venezuelan country, has now left us, but his memories, as numerous as his botanical collections, will always accompany us from tepui to tepui, together with the gratitude of having had the privilege to be one of his students!—*Otto Huber, Caracas, Venezuela.*

I first heard of Julian Steyermark when I was a student at the University of Wisconsin. Dr. Hugh Iltis said he wanted to prepare a flora of Wisconsin that was as good as Steyermark's *Flora of Missouri*. Julian enjoyed hearing that.

I first met Julian when I went to Venezuela in 1977 as part of the joint Missouri Botanical Garden and Herbario Nacional de Venezuela project sponsored by NSF and CONOCIT. When I arrived, Julian was skeptical and concerned and told me about the difficult conditions: rain, heat, insects, snakes, and other perils. Julian, Francisco Delascio, and I went to the Delta Amacuro (delta of the Orinoco River) for a month. The collecting and the trip were exciting and one was able to ignore the difficult conditions. I quickly learned Julian was very good at spotting plants to collect. He first started using clippers when he saw me using them and we sometimes joked that he learned to collect plants from me (he had 114,000 collections when we met).

Numerous field trips with Julian were a privilege. I learned many plants from him and how to find specimens to collect. We frequently bet a milkshake if we thought we could catch the other person not knowing a plant to family. Even a sterile plant was game if that person collected it. Usually I could catch him only if it was a genus that was unusual for the family and the genus was new for Venezuela. We also bet milkshakes for guessing how many plants we had collected before we pressed and numbered them. I, also he, sometimes would collect numerous extra mosses so the competitor's guess would be too low. Once, after Julian had guessed right three days in a row, he stated his guess aiming at a fourth win, then I guessed one lower, and Ángel González guessed one higher. Julian had to do something else. Ángel and I pressed the plants and wrote the field notes. It came out to Julian's number! Ángel and I decided to trick him. One species of herb had both flowering and fruiting individuals. We split them into different collection numbers. But Julian had the last laugh. Not only were they different species, they were different genera! We also guessed at arrival times for a milkshake. Cora, Julian's wife, said they had bet ice-cream cones when they did fieldwork in Missouri.

Julian loved to try different restaurants and go to the movies, and many of his friends enjoyed going with him. For a long time, Julian was my closest friend. Julian had a good sense of humor and it was fun to tease him. But it did annoy him when I said I was from Missouri and to show me. Gerrit Davidse did the same. For a long time he didn't consider us Missourians.

He often corrected my Spanish. I sometimes joked that Julian taught me Spanish. He vehemently denied it, but everyone else liked it.

When he came to Missouri, he had to get his driver's license, and I had to teach him to drive my car. Later, I joked I had taught him how to drive. He would mention the first two things the driving examiner asked were the lights and horn, and I hadn't shown him those.

Julian claimed that he had shaved every morning since the thirties. We could be short of water and he would still shave. He, Bruce Holst, and I were almost stranded on top of a tepui without our things. Bruce and I kidded him that we would see him unshaved. But then we decided he would shave with his machete. The helicopter came so we didn't find out.

Julian and I were in some very risky, potentially dangerous places in collecting. But the most worried and most concerned I ever saw him was when we arrived back in Caracas and he couldn't find his hairpiece. It frustrated him when women saw him without his hairpiece the first time in the field and told him they thought he looked better without it.

When we were stranded on Cerro Duida, wet, with no shelter or supplies, in a potentially fatal situation, Julian joked about dying on a tepui. We assured him that was fine as long as it was some other tepui.

In the field Julian often remembered collecting the same rare species 30 years previously. An amazing number of species were either described by him or named after him. I wonder what level Venezuelan botany would be at if it were not for Julian. He worked fast, long hours, and accurately.

One could go many places in Venezuela and local people would remember Julian when he was there 20 to 40 years previously.

Identifying specimens, I worked on many different plant groups. Julian was a good friend because I could talk about many different groups and he had worked on them also.

For quite a while when I ran into a problem with a plant group or if I had a plant I couldn't identify to family, my first reaction was still to go ask Julian, only to remember Julian was no longer here.—*Ronald Liesner, Missouri Botanical Garden.*

I first met Julian Steyermark in October, 1963, at a difficult time in my life, and I am proud to say that since that time, he has helped me more than anyone else.

At that time I was an unemployed and completely frustrated young man 24 years old; and just "to kill time," I decided to draw flowers. So I began to go around with some paper and a box of color pencils, and devoted myself to drawing flowers in Caracas near where I lived in a student dormitory. After a month or so, I had checked all the gardens, houses, and whatever natural vegetation there was around and had exhausted interesting subjects for drawing and so expanded into surrounding neighborhoods, eventually reaching the Botanical Garden of Caracas, where there was a large variety of exotic and beautiful flowers.

I remember that one day, while concentrating on trying to reproduce the colors of a "bird of paradise" flower (*Strelitzia reginae*), a man came up to look at my work. I had seen him occasionally on previous days, but we never had spoken to each other. He was August Braun, the head gardener. After exchanging some comments, he told me that there was no artist at the Botanical Garden, since the former artist (the late Mr. Ebersteins) had retired four months earlier; and he suggested that I show my drawings to Dr. Lasser, the director.

The following day I took some of my best drawings and showed them to Dr. Lasser. He liked them but said that drawings needed for scientific publications had to be more "objective" and made with black india ink. As I had no experience with that kind of drawing, he introduced me to Dr. Julian Steyermark and asked him to give me some orientation. So I met the man, and got the job!

After I had gained some confidence, in 1963 Julian asked me to draw a new species that he was describing, *Palicourea chimo*, and I complained that I had only herbarium specimens, not live plants. Julian, who also began his botanical career as an artist, understood and helped me look for a solution and invited me along on a trip to Naiguatá, on the northern side of the coastal mountain range of Venezuela, where he had not been before. The *Palicourea* was encountered and drawn fresh.

On the two-day expedition we found a new species, which Julian named *Heisteria olivae* (later placed into the synonymy of *H. latifolia*) to honor our guide, the young architect Francisco Oliva Esteva [see recollections in this volume].

Julian was so impressed by the rich vegetation there that two weeks later we went back to explore further. As Julian had begun his botanical activity in Venezuela in search of quinine plants and was an adviser to a large drug company in the U.S., he was always interested in potentially useful plants as suppliers of drugs. On our second expedition to

the coastal range, we found a big *Lacmellea* tree, called "vaco negro" (black cow) by our guide, who stated that its sweet, milky sap was used as a remedy for asthma. Since we found only flowers and fruits on the ground, Julian felt frustrated, but I returned a few weeks later, climbed the tree using a liana "rope," and collected several complete specimens. I illustrated these, and Julian named *Lacmellea costanensis* as a new species.

So delighted was Julian with the scenery of those slopes facing the sea, completely carpeted by virgin cloud forests, that he soon made yet another expedition there. On this third trip, we went with Mr. G. C. K. Dunsterville, the great orchid artist, and his wife, Nora. Cora Steyermark also came with us, but, as she was suffering from some bad health and could not match our pace, Julian went ahead with a bunch of yellow and red woolen threads, dropping them from time to time along the trail for her to follow. So, late in the afternoon, Cora reached us bright with joy and carrying all the threads she picked up along the trail.

On this same trip, Victoriano Carreño Espinoza joined us. Julian had met him a month earlier on a previous expedition to Cerro Humo in the eastern peninsula of Paria. He was so satisfied with Victor's knowledge of plants, skill, and enthusiasm, that Julian brought him to Caracas and helped him get a job in horticulture at the Central University. Victor continued to work with Julian and quickly became his faithful and efficient assistant on many expeditions throughout Venezuela during a fifteen-year period.

When I met Julian, he was living in an apartment complex called "Residencias Magnolia" located in Los Palos Grandes, Caracas. The apartment had a terrace where he kept plants that he brought back from his botanical expeditions. He would lead visitors on a ritual tour around the garden to give an explanation of the plant names and the regions they came from, with considerations about their color, shape, or scent. But, Julian's expeditions were so frequent and fruitful that the apartment's terrace became too crowded, and about 1971 he moved to the suburb of Santa Eduvigis. There he had more room to display his plants and on the back side of the house he created a miniature jungle under a mango tree. In some cases Julian collected sterile plants, which he brought home until they flowered and then made herbarium specimens from them.

Besides the small garden space, noise from traffic, and the fact that their house was broken into bothered Julian and Cora, so in mid-1975 they found a new house in the neighborhood of Santa Fe Sur. They were particularly pleased with it, because from it they enjoyed a complete view of Avila National Park across the Caracas Valley, and it was close to a place officially listed as a "green area," where supposedly no other buildings could be built. But several months later, in spite of all the official statements, construction began on a huge apartment complex whose wall reached right up to the Steyermark's garden. He felt very frustrated, and in his field book he remarked sadly, "Nov. 20, 1975. Destruction of green area back of our home."

Yet the new house still had room for gardening, and the Steyermarks displayed the beautiful collection of bromeliads on the porch and put the aroids, orchids, begonias, peperomias, and ferns under a plastic net. In the center, there was a planter of red roses, surrounded by several *Hippeastrum* lilies, and another plant of rosemary surrounded by the thorny *Euphorbia splendens.* In back, towards the new apartment complex's wall, there was a *Chrysalidocarpus lutescens* palm, a *Tibouchina semidecandra* with big purple flowers, a *Mussaenda erythrophylla*, a healthy *Clusia minor* with waxy rose flowers, a terrestrial *Cyrtopodium* orchid, and other miscellaneous herbs. On the right side, climbing on the fence was *Aristolochia ringens, Heliconia caribaea, Nicolaia elatior*, and *Lafoensia* with white flowers pollinated by bats. In a pot, there was also a "lily of the valley" with very fragrant white flowers that Julian especially enjoyed. On the side of the garden close to the porch grew a row of *Iris confusa* that never bloomed. Once a month, Victor went to the house to cut the grass and clean the garden.

Cora, a member of the Audubon Society, enjoyed observing birds, and every day would put bananas and oranges in a feeder to attract them to the garden, and sugar water for the hummingbirds. She kept a diary of the garden and recorded the exact date of blooming for every plant, days of rain and sun, and other data for the garden's management. She was also one of the founders of a garden club, which in 1973 created a scented garden for the blind along the avenue Rómulo Gallegos in Caracas.

On many occasions Julian would honor me with an invitation to dine in his house, where I thoroughly enjoyed Cora's excellent cooking, especially the pies and brownies. Sometimes when we came back late at night from some expedition, he invited me to sleep in their house in the guest room. The following day, of course, I would get a delicious

breakfast. I remember that when we sat at the breakfast table, Julian and Cora would recount the dreams they had the night before.

On a trip to Puerto Cabello in 1973 with Julian and Victor, I found out that Julian had a love for snakes. We walked along an old canal breached in areas and useless due to many rocks and earth that had fallen into it; but in a corner, under a little waterfall, it was full of clear and fresh water. Julian, who loved to drink from sparkling streams, put his right hand on the edge of the water and bent over to take a drink (with the left he was holding the plant press). When he finished drinking, and before he stood up, he spotted a poisonous snake out of the corner of his eye, a fer-de-lance (*Bothrops atrox*), just between his hand and his cheek. Victor hurried there with the machete to kill it, but Julian didn't let him; instead, he pushed and chased the snake away into the high vegetation.

In 1983, Julian returned to that area again with Paul Berry and me to gather specimens of *Selaginella gigantea*, but the old trail was completely lost. Paul and I managed to reach the *Selaginella* site, but just as we arrived, a heavy thunderstorm came up. Paul hurried to make a collection of the rare *Selaginella*, and then we headed straight down the mountain, since we lost our trail very quickly. When at last we reached Julian half an hour later, the rain still falling, we found him sitting on his press, trying to protect himself with a completely wet piece of paper but he regained his spirits as soon as he saw Paul's collection. All that area where the *Selaginella* is found now belongs to the San Estaban National Park, created in 1986 thanks to Julian's enthusiastic report.

In October 1970, Julian joined the Venezuelan Brazilian Frontier Commission in a survey of the Cerro de la Neblina, the highest mountain in the Guayana, and he collected as intensely as ever. While participating in that trip, the expeditionaries were sent supplies from San Carlos de Río Negro (Venezuela) and Cocui (Brazil) by helicopter, so Julian decided to send his first lot of collections ahead to San Carlos, preserved in formol in plastic bags; but, due to confusion, the plants were unloaded in Cocui. When Julian returned to Caracas, he realized that a lot of his plants were missing, so in March of the following year he sent me down to San Carlos and Cocui to see if I could find the lost collections and bring them back. When I met the Brazilian officer in charge at Cocui, he told me that he had been there only since January, and that the soldiers, cleaning the warehouse, found a lot of very bad-smelling plants and threw them into the Rio Negro.

At that time Julian was preparing a monograph of the Rubiaceae for the *Flora of Venezuela* to which I contributed as an artist, and in 1973, when I received my degree at the Central University, I resigned my job at the Botanical Garden and turned to teaching. Julian complained about my decision and told me that he had a lifelong dream to write a flora of the Guayana, for which he would like to employ me as the artist; but at that time I didn't see how it would be possible. Anyway, I kept in contact with him, and from time to time, on the weekends or during vacation, he would invite me to join him on some botanical expeditions, even though at that time he was plagued by arthritis of the hips. As Julian could not walk like he used to, he needed extra help on his collecting trips.

In 1973 Julian was asked by a governmental agency to make botanical surveys of several coastal areas recently designated as national parks, and he invited Victor and me along. We would rent a boat for the day, and Victor and I would go out with a bag and a machete and collect samples from every plant we saw. Then, we would go back to the boat, where Julian cleaned the specimens and put them in his press. In the evening, we returned to the hotel with the plants, and Julian, keeping with his usual routine, worked for hours to number the specimens and to make notes on habit, habitat, and other peculiarities that he observed about the living plants. On the following day when the employees went to clean the apartment, they would complain loudly about the mess.

In February 1974, Julian joined the great expedition directed by Charles Brewer-Carias to explore the biggest sinkhole on top of Cerro Sarisariñama in southern Venezuela. Victor went with him since he was having difficulty walking at that time. Even with the problems getting around, he managed to collect more than 1,000 plants in 20 days, many of them rare, including 50 new to science. From the bottom of the sinkhole, Charles sent up a pretty little melastome with white flowers and a shaded rose-colored ring around the calyx. It turned out to be a new species that John Wurdack of the Smithsonian Institution named *Phainantha steyermarkii*. For his part, Julian felt so satisfied and grateful with Victor's work, that he named three new species for him: *Psychotria carrenoi*, *Phyllanthus carrenoi*, and *Sloanea carrenoi*.

During the several months before the expedition to Sarisariñama, Julian had been corresponding with people who had had hip operations to correct arthritis problems. They told him that they had felt much better after the surgery, so at last he decided

to undergo the operation. Since he had to be operated on one side first, and then six months later on the other side, he had to stay at home for a whole year. But how was anybody going to convince Julian to rest? That word was unknown to him, and in fact I suspect he was afraid to rest. For that reason, it did not surprise me that he soon found a way to keep busy at home.

His good friend Otto Huber had been preparing a list of all of the plants in the national herbarium ever collected on the south slopes of Avila National Park, the mountain that rises above the valley of Caracas to the north. Since Otto was an ecologist, he proposed to Julian that they coauthor a book to be called the *Flora of Avila*. Julian was fascinated with the idea, but he insisted that the value of such a flora would increase if it also covered the less-explored northern slopes.

As he was recovering in a hospital room that had a view of Avila high in front, he was inspired to write the following phrase in the introduction to the flora in reference to the fantastic view of the mountain from the city: "We see this beautiful green panorama as we look through the windows of our houses, offices, colleges, *hospitals* or factories."

Surely when Julian planned the *Flora of Avila* he had in mind the style of his huge and successful work, *Flora of Missouri*. Since that was lavishly illustrated, he wanted me to draw as many species as possible in every plate, just like in his previous work. He didn't want to prepare a strictly scientific work, but one that was usable by many different people. One of the ways that he did this was to insist that the publisher include a metric scale on the back cover, with the hope that the flora would be carried along up the mountain and used on the spot to identify plants. A hopeful assumption, indeed, but one that demonstrated Julian's interest in making plants known and loved.

So, we began work on the *Flora of Avila*! I had to make drawings from live material, and then bring them back to Julian to be identified. As the work progressed, he began to complain that I had too many drawings of orchids and other showy plants but few or nothing of several families; and as time passed, we reached a serious impasse. Luckily for us, there was Otto Huber, who could throw water on the flames, and the work went on. It was hard for Julian to type, due to the semireclined position in which he had to remain, so he would turn his manuscripts over to Cora, who was the only person able to read and interpret his thick scratches. Thus she also was a member of the flora team. Julian was later awarded the prestigious "Order of Henry Pittier" by the Ministry of the Environment for the flora.

One peculiarity that I observed in Julian's character was that during his fieldwork, he never dared to identify a plant to species, only to genus. For example, once I asked him, "Julian, how do you like that nice *Palicourea fendleri*?" Immediately he criticized my confidence, which he termed as an expression of ignorance and presumption, and pointed out that *P. fendleri* was known only from the coastal range of Venezuela, and now we were in the Andes . . . . Only later, at the Botanical Garden in Caracas, would he make a decision on the identity of a plant by checking it against herbarium specimens or sending it to one of his colleagues. Once, I told him that I felt that he was too insecure about identifying plants. He answered sharply that he was a scientist and I was only a rank amateur, that ignorance is petulant, and that I should be more careful in my opinions.

In those years, Julian also devoted his weekends to a survey of the plants of the wild areas around his neighborhood of Santa Fe, which at that time was being encroached upon by housing developments. That work was later included in a paper by Paul Berry and Julian entitled "Florula of the deciduous forests of Caracas."

As a scientist, Julian was absolutely objective, and he made no statement without proof to back it up; but sometimes, I thought him to be too objective. For example, when we were working on the *Flora of Avila*, I was fascinated with a beautiful orchid, *Oncidium papilio*, growing in Julian's garden, which in the thirties had been collected "close to Caracas" according to the label. I argued to him that "close to Caracas" might mean "in Avila," but Julian cut me short and said that he, as a native of Missouri, was a "show-me-man," and therefore, he wouldn't include any species in his treatment if not supported by a more precise collecting locality. But, if I were to make a collection of that orchid from the mountain itself, he would include it in the flora . . . . I did look for it indeed, but I couldn't find a specimen; that is, until 1985 in the northern side of the national park, seven years after the flora was published.

In September 1979, Julian went back to Missouri for a couple of weeks for the dedication of the Steyermark Woods. Cora stayed in Venezuela alone in their house, and an American lady who lived close by kept in contact with her and took her to the market whenever she needed to go. Cora felt very uneasy and alone in Venezuela, and Julian was making plans to bring or send her back to Missouri. In fact, since some time earlier, he had

been in contact with Dr. Peter Raven, Director of the Missouri Botanical Garden, and had told him of his desire to write a *Flora of the Venezuelan Guayana*. Dr. Raven was interested, and they began to consider ways to produce it. Although Julian had become a Venezuelan citizen, he realized that the only way to obtain the help that he needed was to return to the large herbarium in Missouri, and so he made final plans to leave Venezuela with Cora in the spring of 1984.

All of his careful plans changed abruptly in October of 1983. One night, when he arrived home from the botanical garden, he found Cora tied to a chair, very scared. What had happened? That afternoon, somebody rang the bell at the entrance and when she opened the door, there were two young men at the gate. One of them pointed a gun at Cora and ordered her to open up. She did as they said, and when they entered, they tied her to a chair with a blanket and searched the house. They found very few things of interest and soon left, leaving Cora tied to the chair, where she stayed until Julian found her hours later. He called the police immediately, and when the officers arrived, and as a matter of routine, they asked Cora to show them her passport. She went upstairs, still very upset, and on her way back down lost her footing and fell, breaking a bone in her right leg. Her leg was set in a cast, and she was released from the hospital, but a couple of weeks later she contracted pneumonia, and a week later, on November 4, 1983, she passed away at age 92. Her last wish to return and see her country again was unfulfilled.

I visited Julian frequently in the following weeks. He spoke very little about what had happened, perhaps trying to forget as quickly as possible. He kept busy working and asked me seriously about contributing the drawings for the flora of Guayana that he had planned. In order to motivate me, he placed at my disposition the thousands of color slides he had taken during many years of exploration. I started by choosing close-ups of flowers, which would be the most useful for my work; but as I went on, I was impressed by the many beautiful slides of landscapes, and an idea came to my mind: to write a book on the Guayana using many of Julian's slides. So, without telling him anything, I wrote an essay on the history of the search for El Dorado, entitled "En la Tierra del Oro," and added to it 100 of the slides. When I had the manuscript completed, I showed it to Julian, who was at first confused, because he didn't understand that I had tricked him a little bit. Anyway, after he read the manuscript and made some corrections, he agreed that I should carry out the plan and went along with me to an editor, who promised to publish it as soon as possible, though it was not completed until December of 1988, too late for Julian to see it.

In December 1983, I began the drawings for the *Flora of the Venezuelan Guayana* using the provisional survey of the herbarium in Caracas that Julian made to find out which families were known from the area. In April of 1984, he moved back to his hometown of St. Louis, but only a few months later he came back to Caracas for two or three months to begin checking the herbarium systematically to record all of the plants collected in the area covered by the intended flora. And in February of 1985, Julian was in Caracas again. This time, he had with him a young man, his efficient assistant Bruce Holst, who helped in the general inventory of the herbarium; he was admired for his ability and correct Spanish.

Until then, except for the short trip in 1971 in search of Julian's lost plants in San Carlos and Cocui, I had never been on any expedition south of the Orinoco River. Julian wanted to give me an opportunity to see as much of the Guayana as possible now, to help me in preparing the drawings for the Flora by taking pictures, or making drawings from live plants, as I preferred. So, in Easter week of 1985, Julian, Bruce, and I headed for the Gran Sabana, in Bolívar State, with the intention of going as far as possible in the ten days that we had.

On that trip, we rented a car called a "Zephyr," a clumsy, two-wheel drive that, when weighed down with all of our gear, barely cleared the ground. Because of the busy vacation week, all of the four-wheel drive vehicles were already rented. On the rough roads of the south, everybody looked at us in astonishment since it was the *only* two-wheel drive in the whole Gran Sabana, but Bruce managed to sort out the numerous ruts in the road and cross the streams to make it all the way to Kamá Falls. Along the way, we collected mostly along the road since Julian didn't want Bruce or me to go too far into the woods and use up too much time, but we managed to find numerous plants to sketch and photograph that would be valuable for my illustrations.

On our way back down to the lowlands, we had a funny incident with a group of university students camped by the side of the road who were in charge of checking the cars returning to the north and helping the tourists with information. As we slowed

down to pass them, the guard on watch blew his whistle for us to stop, and when he saw some plants that we had in the back of the car, he called for the leader to come out of his tent. He asked for our identification and told us that it was forbidden to remove plants from the Canaima National Park. Julian answered that he was Dr. Julian Steyermark, working for the Ministry of the Environment and . . .

"Are you Dr. Steyermark, the author of the *Flora of Avila*?" he asked in delight. "I have wanted to meet you for many years to congratulate you on such a beautiful book!"

Immediately he called all of his helpers to come out and insisted that all of us line up for a picture to be taken with our arms around each other. When the photographer apologized for a delay in taking the picture, Bruce mentioned that there was no hurry since he was standing next to the most beautiful girl of the group.

In August of the same year, Julian and Bruce were in Caracas once more. On this visit, Julian received his retirement payment and immediately purchased a Toyota Land-Cruiser for use on expeditions by both the Caracas Garden and Missouri Botanical Garden. We took it on its maiden voyage to Puerto Ayacucho in the Federal Territory of Amazonas (1–13 September 1985). We had some trouble at the crossing of the Orinoco since a fierce storm was coming up that made the pilot of the ferry think twice about crossing the wide river. But there was a long line of cars waiting, and at last, some people convinced him to make the trip, hoping to beat the storm. As soon as we were well out into the river, it started to rain, and big waves splashed over the floor of the ferry, obliging us to take refuge under the covered area. Many passengers began regretting having started the trip, and we were beginning to think that we might not make it to the other side. Apparently Julian was not at all concerned, even though his new car was perched on the front of the ferry, since he sat quietly under the overhang seemingly enjoying the roller coaster. But after one hour or so of being tossed around and getting soaked by the waves, we reached the town of Caicara on the other side. Bruce overheard one of the ferry attendants say that our trip was the roughest that he ever made.

On that expedition, I was fascinated by the many strange flowers that we found, especially with a half-dozen species of *Mandevilla*, a vining genus of the Apocynaceae family with showy yellow flowers (a couple of new species would be described later from those collections), and different species of purple morning glories and mallows. Of course, when I saw a pretty flower, I asked Bruce to stop to take a picture; but Julian started getting bothered with so many stops, and he ordered Bruce to follow his instructions, not mine, and to go ahead without stopping any more to make better time. Julian looked very bothered when he said that, and we went on a short time without speaking, all of us feeling tense. I knew Julian as a mild-mannered man, who only on a few occasions would lose his patience, and usually for just a short time. So, I began to tell him in a humble voice: "Julian, suppose we see a donkey on a bicycle. Shouldn't that be a reason to stop and take a picture? . . ." (No answer). Again, a bit later: "Julian, and if we saw a mammoth flying over that boulder over there, wouldn't it be a good reason to stop and take a picture? . . ." No answer! I understood that maybe I went too far with my stupidities, and I decided to shut up and resign myself to his wishes . . . . Suddenly, Julian cried:

"Bruce, stop! . . . Bruno, did you see those big yellow flowers in that bush over there? . . . Have you already taken a picture of them?"

On the way back to Caicara a few days later, Bruce was driving slowly on the muddy road to avoid the many potholes, but Julian asked him to speed up, thinking that when we arrived in Caicara at the hotel, he had to record in his field book all the plants he collected that day. Bruce tried to obey, but when he came across any rut, he would slow down again. At last Julian lost his patience and ordered him to turn over the wheel; and the Land-Cruiser started away at full speed, jumping, splashing, and shaking us up. We arrived at Caicara early that evening, and we were the first customers in the restaurant, as was usual with Julian.

The following day, early in the morning, we crossed the Orinoco River again, this time with a nice sun and good weather, and by evening we were in Caracas.

As a man who loved nature, not only to enjoy it but also to make it known and be loved, he supported with his own money several expensive expeditions to Guayana. He also paid for some botanists from Venezuela to visit herbaria in the United States and for some U.S. botanists to go to Venezuela to work on treatments for his flora. As he was demanding with himself, he used the same standard for others. I was in the office one night when Luis Marcano Berti, a Venezuelan botanist whose trip to the New York Botanical Garden was funded by Julian, called. "Are you also working at

night and on the weekends?" Julian asked. "Yes!" "Oh, very good," answered Julian contentedly.

In my case, although he wanted me to work hard on the drawings, he wished too that I would be able to see and enjoy from time to time the natural beauty of Missouri and especially of the Ozarks. To help me out, he asked Bruce to take me camping some weekend, which we did several times. So, with their help, I was able to get to know some of that wonderful country of Missouri, and also gaze at the stars through Bruce's telescope. Bruce, for his part, would tell me that in late October, when Julian was better, we would all go out again together to see the fall colors, which delighted Julian so much.

The weekend after Julian passed away, Bruce took me out to the Ozarks. The sun was bright that afternoon, and the many colors of the falling leaves were spectacular. We regretted that Julian was not with us to enjoy one of his favorite shows of nature.

That night, Bruce and I sat a long time looking at the fire. The words came out with difficulty, and several times I had to bite my lips not to weep. Both had lost a great friend, and I missed a man who for me was like a father. At that moment we felt closer than ever before, feeling the responsibility we now had to bear of completing Julian's great dream, but glad to have been with Julian in his last hours.

A few days later, while writing down these memories, a letter came from Victoriano Carreño, dated Caracas, October 4, 1988. It said: "Dear friend, I heard that you were sick, and I am praying to God for your quick recovery. All of us remember you, and we hope that you can visit us again . . . ."

Surely, Julian would have enjoyed receiving this letter with the sincere wishes of Victor, the faithful field assistant who during many years helped him get a bit closer to his dearest dream.—*Bruno Manara, Caracas, Venezuela.*

The return of Dr. Julian A. Steyermark to Missouri during the last week in September [ca. 1978] provided me with a chance to talk again to my esteemed friend and to reminisce about my first experiences with him over two decades ago.

I had grown up on Steyermark's *Spring Flora of Missouri*, which I found very useful in adjacent southern Illinois. While I was doing research at the Missouri Botanical Garden 1954–56, working on my Ph.D. at Washington University, I was constantly reminded of Dr. Steyermark because of his vast collections in the MBG herbarium, because of his prodigious writings, and because of the stories retold about him by Edgar Anderson, Bob Woodson, and others.

Following my Ph.D., I began my professional career in the Department of Botany at Southern Illinois University in January 1957. It was my great fortune that during the three-month spring quarter in 1958, Julian Steyermark was offered a Visiting Professorship in the Department of Botany at SIU. The impact that those three months had on my professional career cannot be overstated.

Our department at that time was in cramped quarters. I already was sharing a 16 by 8-foot office with Professor John Voigt, the departmental ecologist. Since Dr. Voigt's interests and mine were more closely aligned to Dr. Steyermark's interests, the three of us were crowded into this small office.

Steyermark and I spent every day and partway into nearly every evening working side by side. He was putting the finishing touches on his *Flora of Missouri* and I, along with my wife, Beverly, was revising Jones's *Flora of Illinois*. Often Steyermark would quiz me on some specimen he was working on or sketching. Many species previously unknown by me were quickly and eagerly learned.

While much of the three months was devoted to serious botany, Dr. Steyermark would take a little time off now and then to come to our home for dinner. On one occasion he took my wife and me to the local movie theater to see *War and Peace*. I recall the incident vividly because Julian insisted on picking us up in his vehicle, an International Scout built high to enable him to negotiate Missouri's back roads. The Scout was so high that I had to climb awkwardly. My poor wife stood helplessly at the door until Dr. Steyermark boosted her up into her seat!

One of my most pleasant recollections was an overnight visit to Steyermark's estate near Barrington, Illinois, north of Chicago. Julian had talked so often about the wildflower preserve he had built that my wife and I were thrilled to be invited to see it. We arrived early one afternoon. Julian guided us over about half of the property, pointing out with great enthusiasm the many species transplanted from the Ozarks. That evening we talked of plants, browsed through his extensive library, and listened to classical music.

We awoke the next morning to the delightful smell of bacon frying. Cora, Julian's wife, had prepared a feast, including the most delicious baked eggs my wife and I had ever eaten. The rest of the morning was spent walking over the remainder of the grounds before we all began the long drive back to Carbondale.

From mid-March to late April 1958, Steyer-

mark enthralled me with stories of his experiences. I was particularly excited about his rediscovery in 1957 of the very rare and little-known *Geocarpon minimum*. This species had been found originally in Jasper County [Missouri] in 1913. This remained the only known station until Steyermark had rediscovered it in St. Clair County [Missouri] in 1957. My nagging at Dr. Steyermark to show me *Geocarpon* paid off. He agreed to take Dr. Voigt and me with him on a three-day excursion to see if we could discover additional stations for this dwarf rarity.

We left Carbondale on May 2, heading in the general direction of Springfield, Missouri. Leaving Cape Girardeau, we stopped briefly at the Bollinger Mill and then headed into the Ozarks. Up and down lettered and double-lettered county highways, past shortleaf pine woods, over clear, rock-bottomed streams we went, Steyermark pointing out species right and left. We made frequent stops, usually after an enthusiastic comment such as "Wait! There's a county record." I tried to absorb all the species as fast as I could, but Steyermark never relented. We screeched to a halt in Bollinger County, pulling off the road next to a steep, wooded cherty slope. Julian asked if any of us had ever seen the little sedge *Scirpus verecundus*. We replied in the negative, and off we went down the slope. *Scirpus verecundus* was not known from Bollinger County, but Julian was optimistic, saying that this slope looked just right for the little plant. In what could not have been more than five minutes, the woods echoed Steyermark's voice: "Whee! Over here. I've found it!" Scrambling over the treacherous chert, Dr. Voigt and I made it to the kneeling botanist who crouched over a four-inch-tall tuff of green. I had seen my first *Scirpus verecundus*, and I was never to forget the habitat. Some 15 years later, while exploring in Alexander County, Illinois, I camp upon a similar steep, cherty slope. Recalling my earlier experience, I began to comb the woods and was rewarded by making the first discovery of *Scirpus verecundus* in Illinois.

By late afternoon we had reached Dallas County and were heading along Route 43 when Steyermark observed that the little chickweed on the road shoulder looked peculiar. On closer look, the plant indeed was different from anything we had ever seen. We learned later that the plant was *Cerastium pumilum*, a new record for Missouri.

We persisted beyond supper and into the duskiness of twilight. By dark, we were still on the road. I began to understand how Steyermark had been able to canvass every square foot of Missouri in 30 years—he never stopped to rest. I saw my first

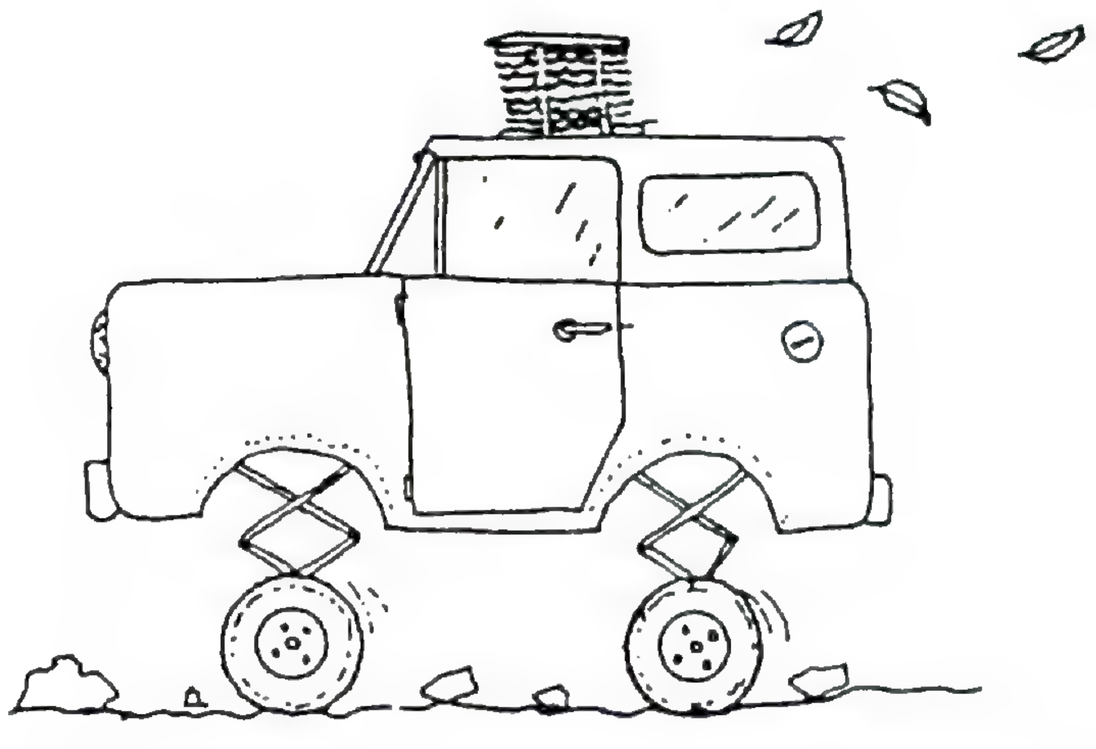

FIGURE 5. Steyermarkmobile. Contributed by Robert Mohlenbrock.

Ozark tarantula, scurrying aross the road in the glow of our headlights. Finally we stopped for camp at about 9:30, reeling from the vast amount of information imparted by Dr. Steyermark.

We arose early on May 3 in anticipation of seeing *Geocarpon*. We had entered Polk County [Missouri] near Graydon Springs when Dr. Steyermark announced that we had arrived at a likely looking spot for *Geocarpon*. It was a glade on a west-facing sandstone escarpment next to Coates Branch, a tributary of the Little Sac River. We quickly found *Isoëtes butleri*, *Talinum parviflorum*, and *Arenaria patula*, species known to be associated with *Geocarpon* at its other stations. Then, in a small, moist depression on the glade, we spotted it—dwarf, two inches tall, semi-succulent. At this stage, the plants were wine-purple. Once we knew what we were looking for, we began to spot another, and another and yet another. Our discovery marked the third known location for *Geocarpon* in the world! On the same glade, I also saw for the first time in my life *Selenia aurea*, *Saxifraga texana*, and *Collinsia violacea*.

Our spirits were buoyed by these discoveries. We hastened into Green County and stopped at a likely looking sandstone glade near Pearl. We noticed *Selenia aurea* and *Saxifraga texana* from a distance and, more closely, *Isoëtes butleri*. It certainly would be just a matter of time. Sure enough, the wine-purple plants of *Geocarpon minimum* became evident after we had wandered into an adjacent glade. I don't recall how many specimens there were but I would think there were dozens of them.

As we were hopping over the glade in our crouched positions, we happened upon a small plant previously unknown from Missouri. It was *Scleranthus annuus*, the awlwort of the Caryophyllaceae.

FIGURE 6. Julian Steyermark. Date unknown.

With our success in finding *Geocarpon*, we headed into Dade and Cedar counties, stopping at several glades. Much to our consternation, we couldn't find *Geocarpon* at any of them. By late afternoon, we started back to the east where we had planned to camp at beautiful Alley Springs. Darkness caught us again while still on the rolling hills of the Ozarks. The night scarcely slowed Dr. Steyermark as he continued to name roadside plants as our headlights struck them. "*Andropogon elliottii*," he shouted once, as we whizzed by a clump of two-foot tall grasses. Most people have trouble identifying this species in the daylight with the specimen in front of them, but Steyermark's identification was right on the money.

We got to Alley Springs at last. The long, eventful day was conducive to good sleeping, and I scarcely noted that I was spending the first night of my life atop a hard, slatted picnic table!

Next morning we were soon on the road, finding more goodies. About two miles west of Piedmont along Highway 34, we found *Cerastium brachypetalum*, the third collection of it in Missouri. Near Cape Girardeau, we discovered our second station for *Cerastium pumilum*. Since the afternoon was young, Dr. Steyermark expressed a desire to go into Perry County to a deep ravine he had had his eyes on for years. The ravine was new collecting ground for Julian, and he took his plant press with him. He is the only botanist I have ever been in the field with in the United States who carries his press with him. Most of us use plastic bags or tin cans (vascula), and our semiwilted specimens are proof of it. Steyermark had custom-made his own press with a hinged back that opens like a giant book. Our visit to the ravine netted nearly a dozen records for Perry County.

We got back to Carbondale early in the evening, finishing a three-day red-letter trip I will never forget.—*Robert Mohlenbrock, Dept. of Botany, Southern Illinois University; reprinted with permission from* Missouriensis 1(3): 1979.

My first meeting with Julian Steyermark was at the Caracas Botanical Garden in 1960, after returning from landscape architecture studies at the Rhode Island School of Design. At that time, there were very few books in Spanish about local ornamental plants. As a landscape architect, I felt it would be interesting to write a book about tropical trees that would be useful for landscape projects. Gradually, my visits to the Botanical Garden became more frequent. Julian was always ready to answer my many questions about trees and other plants, as well as to identify living material that I brought in.

In 1963, we made a three-day expedition to the mountains above the coastal town of Naiguatá in a very rich rainforest at 1,000 m elevation and only about 60 km by road from Caracas. We found many new species there including huge trees, and we collected the bromeliad *Guzmania sanguinea* for the first time in Venezuela. At later dates we went on other trips, and even met at the top of different tepuis with a group from the Terramar Foundation.

In 1962, when I began to write and illustrate a color edition of ornamental trees in Spanish, Julian kindly supervised my work. We also maintained close contact over the next eight years as I worked on my second book called *Garden Plants of the Tropics* (printed in English and Spanish). Julian wrote the introduction for me.

Despite his intensive work in families such as the Rubiaceae, Julian was always intrigued with the beauty and wonderful colors of the Bromeliaceae. The enchanting forms and the extravagance of the flowers fascinated him, something we certainly shared. I began to fancy the idea of making a book on Bromeliaceae along with him. The first step was to compile photographs, including ones

Julian occasionally took of the Bromeliaceae on the tepuis. Because of the difficulties of getting to the Guayana, his pictures were particularly valuable. Soon he agreed to write the text for the book on *Bromeliaceae of Venezuela* with me. It took about five or six years to organize the text and pictures. From 1980 to 1983, Julian was already very involved with the *Flora of the Venezuelan Guayana* project, so I decided to do most of the text in order to facilitate his work. I would generally give him eight to ten pages of text to check and translate; he would review these and return them to me after a few days. He was very adept at translating text from Spanish to English and vice versa. Once, Julian became upset with me because, according to him, I was including too many species, and he had no more time to keep reading, correcting, and translating. Although there were about 230 species prepared, I went on against his wishes to include a few more that I had collected at the last minute. I insisted that he go over these too. He always wanted to please people, so he did the final effort to finish the last translation and corrections for our work. I can still remember hearing him along the corridors of the Botanical Institute saying, "I am very busy with the *Flora of the Guayana* and have no time to do anything else. Please can you stop adding new data to the book?" Our manuscript was handed to the printer just days before Julian left Caracas to move to St. Louis, but then the book took about two years to be printed.

Before leaving his post at the Caracas Botanical Garden, Julian was awarded diplomas and medals together with a reception and a farewell party, by the National Parks Institute in recognition for his tremendous work accomplished in Venezuela. He was most happy and pleased by these honors. After Julian's departure from Venezuela, we kept in touch by mail about the last details and corrections of the proofs of our book. He returned many times to Caracas with his assistant Bruce Holst to work and collect for his monumental *Flora of the Venezuelan Guayana*. Although he was expecting to finish this project, destiny had other plans.—*Francisco Oliva-Esteva, Caracas, Venezuela.*

Libro de la Sabiduría de Salomón:

> Mas las almas de los justos están en la mano de Dios, y no llegará a ellos el tormento de la muerte eterna. A los ojos de los insensatos pareció que morían, y su tránsito, o salida del mundo, se miró como una desgracia, y como un aniquilamiento su partida de entre nosotros: mas ellos, a la verdad, reposan en paz.

Julián Steyermark no está hoy entre nosotros, pero no podemos decir que está muerto, no podemos decir que ha desaparecido; no existe la muerte para un hombre que hizo tantos caminos. Su obra como su bondad son imperecederas.

Su alma se separa de su cuerpo ya inmóvil el sábado 15 de octubre, allá lejos, en tierras norteñas, en la ciudad de Saint Louis. Allá mismo donde nació. Pero la mayor parte de su vida, los mejores años, los pasa con nosotros.

No ha habido hombre que haya estudiado más nuestra flora. La pasión máxima de Julián Steyermark fue la Guayana, con sus imponentes tepuyes, pero también recorrió con sus ojos bien abiertos a toda Venezuela, viendo y colectando muestras botánicas.

Deja una valiosa obra. Era infatigable. Fueron múltiples sus contribuciones: las Rubiáceas, las Piperáceas, exploraciones botánicas de las regiones orientales, nuestra vegetación, la Sierra Imataca y altiplanicie Nuria, la flora de la Sierra de San Luis en Falcón, el Cerro Autana, Cima del Macizo Jaua, Cerro Patao en Paria, el Roraima, el Auyantepuy, la flora del Avila.

Julián Steyermark fue un excelente botánico. Un incansable admirador de nuestra naturaleza. Coleccionó miles de muestras para herbario. Clasificó una cantidad igual. Atendió centenares de consultas. Pero lo más importante es que fue un hombre bueno. Honesto, noble, muy sencillo, extremadamente sencillo, cordial, amable, siempre dispuesto a responder cualquier pregunta. El gran complemento de su erudición era la sencillez.

No podemos decir que Julián Steyermark ha muerto. Tal como está escrito en la Biblia: las almas de los justos están en la mano de Dios, y no llegará a ellos el tormento de la muerte eterna. Ellos a la verdad, reposan en paz.—*Mauricio Ramia, Universidad Central de Venezuela; palabras pronunciadas en el acto de apertura del IX Congreso Venezolano de Botánica, el día 13 de noviembre de 1988 en Caracas.*

Julian took my wife and me for our first look at the Grand Savanna in the Guayana Highland, and with us the Dunstervilles looking for orchids and to whom the place was an old story. As we entered the Grand Savanna, Julian and I stopped on an area of dry open sand and discovered a tiny sundew with one or two sessile flowers in the center of the rosette. Julian named it *Drosera felix* because of the happy event of our visit.

Later on our trip we were camping one night by a small stream, and while Julian was preparing supper, I went out exploring and found an aquatic aroid in a deep pool that the stream had hollowed out of the solid rock. Julian came when he was

free and with his longer arm was able to collect it. It proved to be a new genus, and George Bunting named it *Jasarum*, compounding it with Julian's initials and *Arum* because Julian had discovered so many new genera that such tactics were necessary. Later I contributed with the bromeliad *Steyerbromelia*.—*Lyman B. Smith, Smithsonian Institution.*

I participated in a number of field trips to Missouri when Dr. Steyermark was accumulating vouchers for his flora. The average trip down [from Chicago] was about six hours, and he would continuously quiz me on botanical questions.

Typical questions would be: "What type of placentation occurs in the Caryophyllaceae?" or "What monotypic genus in the Cruciferae is endemic to the Kerguelen Archipelago?" or "Name all of the phanerogamic genera native to Antarctica." In many cases he was actually thinking about the second question while I was working on the answer to the first one. So you get some idea how many questions were involved on a given trip.

I would say that he, perhaps more than any other person, stimulated my interest in taxonomic botany.—*Floyd Swink, Morton Arboretum.*

Julian knew Missouri as did few others, and he had a remarkable memory of people, sites, and plants. The Department of Conservation bought the land where Julian found pondberry [*Lindera melissifolia*] from a man called O. K. Hamlett. We were discussing this site one day and Julian not only remembered O.K.'s name but he described in detail where several of the rare species were located on the property. I had been on the property a week earlier and Julian talked as if he had—not 25 years before.

When the Natural History Section first started to locate and buy significant sites (often with rare or endangered species) we used a list Julian had prepared 20 years before. The same list went into the Natural Heritage Database prepared by The Nature Conservancy and the Department of Conservation.

Thanks to Julian, a number of these areas are now State Natural Areas and protected for those who will come after us. Sand Ponds (the pondberry site), Pickle Springs, and Barn Hollow are examples.

Every time we walk in these places Julian's shade will be there too.—*John Wylie, Retired Natural History Officer, Jefferson City, Missouri.*

Members and friends of the Garden were saddened by the death of Dr. Julian Steyermark on Saturday, October 15, 1988. Steyermark was one of the Garden's best-known research botanists, famous locally and around the world for his botanical collections and publications, and for his strong support for conservation of the environment.

Born in St. Louis on January 27, 1909, Julian Alfred Steyermark enrolled in 1925 in the Henry Shaw School of Botany, a cooperative program between the Garden and Washington University, where he received A.B. (1929), M.S. (1930), and Ph.D. (1933) degrees. He also earned an M.A. degree (1931) from Harvard University. During his early years at the Garden, Julian indulged his other great love, painting watercolors of native flora and plants in the Garden's orchid collection. At that time he began collecting herbarium specimens in Missouri and other states, and by graduation in 1933 he had already surpassed the quantity most botanists collect in a lifetime.

After college, Steyermark assisted Robert Woodson, a research botanist at the Garden. This led to his first tropical expedition, a collecting trip to Panama in 1934. He then taught high school in the St. Louis area for two years before moving to the Field Museum of Natural History in Chicago as an Assistant Curator. For the next 21 years Steyermark worked on the *Flora of Guatemala* and other tropical projects during the week, but continued his Missouri studies in his spare time. A revealing and delightful look at those weekend expeditions from Chicago to the wilds of Missouri was provided by his wife, Cora, in her book, *Behind the Scenes*, published by the Garden in 1984 (and still available in the Garden Gate Shop). These efforts culminated in the massive *Flora of Missouri* (1963). This widely acclaimed manual is often referred to as the state's "botanical bible" and has sold out six printings.

During World War II, Steyermark was sent to South America as part of the government's program to locate new botanical sources for quinine. At that time he first visited the Venezuelan Guayana region, which he lovingly referred to as "The Lost World." (See the Missouri Botanical Garden's *Bulletin*, November/December 1986 and July/August 1987.) His interest in this picturesque area was so great that in 1958 he left the Field Museum to take a position at Instituto Botánico in Caracas, Venezuela. In 1984, Julian returned to the Missouri Botanical Garden, where he strove to complete his last major project, a flora of the more than 9,000 plant species in the Venezuelan Guay-

FIGURE 7. Cora and Julian Steyermark in front of their home at Santa Eduvigis, Caracas, Venezuela, 1965–1970.

ana. This task remains for his friends and colleagues to complete.

Bruce Holst, project coordinator for the *Flora of the Venezuelan Guayana*, said, "It was a real thrill and a tremendous learning experience to work in the field with Julian. He really had an 'eagle eye' for spotting plants, and if you didn't see something that he did, he would let you know it . . . . Fieldwork was very special for Julian. He never took any 'vacation,' he went on field trips instead. He was just *so* excited about collecting plants, it was impossible not to be caught up by his enthusiasm. He always likened collecting to a 'treasure hunt'! Even with his two artificial hips, he would

FIGURE 8. Julian Steyermark on El Avila, outside of Caracas, Venezuela. Date unknown.

plow through brush, crawl over and under logs, fall down, laugh about it and push on . . . ."

Steyermark received numerous honors during his eventful life, including awards and citations from the governments of Guatamala and Venezuela, and the Garden's Henry Shaw Medal in 1979. That same year, the Ozark Chapter of the Sierra Club awarded him a special citation for his conservation efforts, and the Missouri Department of Conservation named the 73-acre Julian A. Steyermark Woods, near Hannibal, in his honor.

To commemorate Steyermark's achievements, the Garden has established a fund to promote botanical research and expeditions in Latin America, particularly in the Venezuelan Guayana region, and to support research on the natural history of Missouri. In addition, the Missouri Department of Conservation and the Garden are revising Julian's best-known book, which will be retitled *Steyermark's Flora of Missouri*, a lasting memorial to a giant among botanists.

A memorial service was held for Julian Steyermark at the Garden on October 25, 1988. In the eulogy, Dr. Raven said, ". . . His last work will be completed here, and will stand as a final testament to his industry and to his scholarship. As for any human being, however, what will prove to be even more important to all of us will be our memories, for Julian Steyermark was an inspirational person, one who projected his own values without trumpeting them, and thereby enriched all our lives, as he did the literature of botany."—*George Yatskievych heads the Garden's joint project with the Missouri Department of Conservation to revise Steyermark's* Flora of Missouri.—*Luther Raechal assisted Dr. Steyermark on the* Flora of the Venezuelan Guayana *and is continuing his work on the staff of this ongoing project; reprinted with permission from the* Bulletin of the Missouri Botanical Garden *77(1): 5. 1989.*

PLANT TAXA DESCRIBED BY JULIAN A. STEYERMARK[1]

Mary Susan Taylor[2]

ABSTRACT

In his 62 years of actively collecting plants (1925–1987), Julian Steyermark described 2,392 taxa, including 1 family, 38 genera, and 1,864 species. He named plants from 26 countries and from 16 states in the U.S.A. Types of taxa that he named are listed alphabetically by family, with author, literature citation, collector, collection number, date of collection, locality, elevation, and depository. Comments are supplied, where pertinent, on never-published names, illegitimate names, and some current nomenclature (which are not referenced in the bibliography). Appendices include eponymy, collectors index, and family index. The bibliography includes 395 references. Statistical summaries are provided.

Julian Steyermark collected his first plant in 1925, his last in 1987, both in Missouri. He collected so many plants, over 130,000 collections, that he received recognition from the unusual source of the *Guinness Book of World Records*. Julian was most known for his *Flora of Missouri*, and his work in Guatemala and Venezuela, yet he described plants from 26 countries and from 16 states in the U.S.A.

His statistical record is astonishing. Julian Steyermark described a single family, 38 genera, and 1,864 species. Including other ranks, he named at least 2,392 taxa. *Taxonomic Literature* (*second edition*) cites an as yet unobtainable reference edited by H. Villanueva, 1977 (Bibl. Alfredo Jahn, Bol. Inf. 9: 9–12) which purports to contain the 'most important of over 350 publications' by Julian Steyermark. It is estimated by the present author that this compilation lacks about 80 references, although the exact number is unknown.

In the list of types families are arranged alphabetically, and species alphabetically within families, then by descending rank within species. Data include the name, author(s), place of publication, collector, collection number, date of collection, locality, elevation, and depository. Current nomenclature (which are not referenced in the bibliography) and accession number of the Missouri Botanical Garden sheet are indicated when found serendipitously. New combinations are not included. A few never-published names are included and correct nomenclature given for sheets known to have been distributed bearing the unpublished name. Author abbreviations follow *Draft Index of Author Abbreviations Compiled at The Herbarium, Royal Botanic Gardens, Kew* and *Taxonomic Literature* (*second edition*). Publication abbreviations are standardized according to *Botanicum-Periodicum-Huntianum*.

[1] Julian never kept a list of what he described or maintained a complete bibliography. He was always helpful with suggestions on where to look for more of his work, and soon I didn't have to prompt him with questions, he would seek me out to ask if I had looked at certain journals. I shall always remember his generous gift of time in talking with me about his life and his work. He was always encouraging, and gracious with advice when I had a thorny taxonomic problem of my own. I am deeply grateful to Bruce Holst, Doug Stevens, Robbin Moran, and George Yatskievych for making valuable suggestions on the manuscript. Dolly Dorigo spent many hours double-checking the indices. Thanks are due to Bruce Holst, Paul Berry, and Luther Raechal for allowing me temporary office space. My friends Roy Gereau, Myra Guzman-Teare, and Amy Pool gave me support and encouragement during the two years I spent working on the list.

Ruellia pedunculata Torr. f. *baueri* Steyerm., Rhodora 51: 118. 1949. *B. Bauer s.n.*; 20 June 1948; U.S.A., Missouri, St. Francois Co., Koester; F (holo).

Ruellia strepens L. f. *alba* Steyerm., Rhodora 54: 258. 1952. *J. A. Steyermark 70292*; 26 Aug. 1950; U.S.A., Missouri, Schuyler Co., tributary to Chariton River, NE of Livonia, 6 mi. SW of Glenwood; F (holo), MO (1703638).

Siphonoglossa hondurensis Standl. & Steyerm., Ceiba 3: 131. 1952. *P. C. Standley 12459*; 18 Sep. 1948; Honduras, Dept. Morazán, región de La Travesía, cerca de Suyapa; F (holo) = *Siphonoglossa sessilis* (Jacq.) D. Gibson, 1973.

ACTINIDIACEAE

Saurauia cuchumatanensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 215. 1947. *J. A. Steyermark 49810*; 31 July 1942; Guatemala, Dept. Huehuetenango, Cruz de Limón, Sierra de los Cuchumatanes; 2,600–3,000 m; F (holo).

Saurauia meridensis Steyerm., Fieldiana Bot. 28(2): 368. 1952. *J. A. Steyermark 56344*; 6 May 1944; Venezuela, Mérida, Río Canagua, near Canagua; 1,065–1,820 m; F (holo).

Saurauia "perseifolia" Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 216. 1947. *J. A. Steyermark 41748*; 24 Dec. 1941; Guatemala, Dept. Izabal, along Río Tamejá, Cerro San Gil; 50 m; F (holo). Note: *S. persifolia* is the correct spelling.

Saurauia veneficorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 217. 1947. *J. A. Steyermark 31081*; 2 Nov. 1939; Guatemala, Dept. Chiquimula, Montaña Norte to El Jutal, Cerro Brujo; 1,700–2,000 m; F (holo).

AGAVACEAE

Agave huehueteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 4. 1943. *P. C. Standley 82039*; 2 Jan. 1941; Guatemala, Dept. Huehuetenango, along Aguacatán road E of Huehuetenango; 1,950 m; F (holo).

ALBOLBODACEAE = Xyridaceae

AMARANTHACEAE

Cladothrix lanuginosa Nutt. var. *caruosa* Steyerm., Ann. Missouri Bot. Gard. 19: 389. 1932. *J. A. Moore & J. A. Steyermark 3795*; 26 June 1931; U.S.A., Texas, Brewster Co., 3 mi. E of Study Butte; 762 m; GH (holo), MO (1012577) = *Tidestromia lanuginosa* var. *caruosa* (Steyerm.) Cory.

AMARYLLIDACEAE

Pancratium guatemalense Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 38. 1944. *J. A. Steyermark 39288*; 13 Apr. 1940; Guatemala, Dept. Izabal, between Escobas and Montaña Escobas, across bay from Puerto Barrios; sea level; F (holo).

ANACARDIACEAE

Tapirira dunstervilleorum Steyerm., Aristeq. & Wurd., Bol. Soc. Venez. Ci. Nat. 26: 159. 1965. *J. A. Steyermark 90883*; 4 June 1962; Venezuela, Miranda, Oritopo, above Los Guayabitos and Baruta; 1,500 m; VEN (holo).

ANNONACEAE

Annona primigenia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 7. 1943. *C. L. Lundell 2213*; Mar. 1933; Guatemala, Dept. Petén, Gavilán, Fallabón–Yaxhá road; F (holo).

Desmopsis guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 156. 1944. *J. A. Steyermark 34304*; 17 Jan. 1940; Guatemala, Dept. Quezaltenango, Montaña Chícharro, Volcán Santa María; 1,500 m; F (holo).

Desmopsis izabalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 157. 1944. *J. A. Steyermark 41543*; 18 Dec. 1941; Guatemala, Dept. Izabal, Río Frío, Cerro San Gil; 75–150 m; F (holo).

Sapranthus megistanthus Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 7. 1943. *P. C. Standley 59219*; 8 Dec. 1938; Guatemala, Dept. Guatemala, Estancia Grande; 600 m; F (holo).

APOCYNACEAE

Aspidosperma decussatum Woodson subsp. *jauaensis* Steyerm. & Maguire, Mem. New York Bot. Gard. 23: 881. 1972. *J. A. Steyermark 98086*; 22–27 Mar. 1967; Venezuela, Bolívar, Cerro Jaua; 1,922–2,100 m; VEN (holo).

Lacmellea costanensis Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 240. 1964. *J. A. Steyermark 92131*; 15–19 Nov. 1963; Venezuela, Distr. Federal, Cerro Naiguata; 1,000–1,300 m; NY, US, VEN (holo).

Mandevilla subcarnosa (Benth.) Woodson var. *angustata* Steyerm., Acta Bot. Venez. 2: 318. 1967. *J. A. Steyermark 93737*; 11 May 1964; Venezuela, Bolívar, Auyan-tepui; 1,660 m; VEN (holo).

Peltastes manarae Steyerm., Acta Bot. Venez. 3: 206. 1968. *B. J. Manara s.n.*; 11 July 1966; Venezuela, Distr. Federal, Quebrada Guayoyo, Cerro Naiguata; 1,000 m; VEN (holo).

AQUIFOLIACEAE

Ilex abscondita Steyerm., Ann. Missouri Bot. Gard. 75: 320. 1988. *T. Croat 59478*; 30 Nov. 1984; Venezuela, T.F. Amazonas, Cerro de la Neblina, Camp 7; 1,900 m; MO (holo—59478), NY, VEN.

Ilex acutidenticulata Steyerm., Ann. Missouri Bot. Gard 75: 321. 1988. *R. L. Liesner 18595*; 12 Mar. 1985; Venezuela; T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca; 1,500–1,650 m; MO (holo—3446418), VEN.

Ilex altiplana Steyerm., Ann. Missouri Bot. Gard. 75: 321. 1988. *J. A. Steyermark 111402*; 4 Jan. 1975; Venezuela, Bolívar, between San Ignacio de Yuruani and San Francisco de Yuruani; 1,200 m; VEN (holo).

Ilex anodonta Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 245. 1940. *J. A. Steyermark 36381*; 22 Feb. 1940; Guatemala, Dept. San Marcos, Río Tonana, between Canjula and La Unión Juárez, near SE portion of Volcán Tacaná; 2,000–3,000 m; F (holo).

Ilex aracamuniana Steyerm., Ann. Missouri Bot. Gard.: in press. 1989. *R. L. Liesner & G. Carnevali 22473*; 26 Oct. 1987; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp; 1,400 m; MO (holo), VEN.

Ilex attenuata Steyerm., Ann. Missouri Bot. Gard. 75: 322. 1988. *N. T. Silva & U. Brazao 60873*; 24 Jan. 1966; Brazil, Amazonas, Sierra Pirapucú, Comissão de Limites BR-1; 1,250 m; G, INPA, MO (holo—3283928), NY, VEN.

Ilex brevipedicellata Steyerm., Ann. Missouri Bot. Gard. 75: 322. 1988. *J. A. Steyermark & B. Holst 130531*; 21–22, 24 Feb. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca, Sima Camp; MO (holo—3446417), VEN.

Ilex brevipetiolata Steyerm. & Wurd., Mem. New York Bot. Gard. 9: 479. 1957. *J. A. Steyermark & J. J. Wurdack 347*; 27 Jan. 1948; Venezuela, Bolívar, Uaipán-tepui; 1,400 m; NY (holo) = *I. subrotundifolia* Steyerm., 1952.

Ilex cardonae Steyerm., Ann. Missouri Bot. Gard. 75: 323. 1988. *F. Cardona 1480*; 16–24 Feb. 1946; Venezuela, T.F. Amazonas, orillas del Río Castanho, afluente del Padauiri que del Río Negro y éste último al Amazonas; 100–140 m; VEN (holo).

Ilex ciliolata Steyerm., Ann. Missouri Bot. Gard. 75: 323. 1988. *R. L. Liesner 19479*; 4 Nov. 1985; Ven-

ezuela, Bolívar, 0.4 km N of El Pauji on trail to Uaiparú; 800–900 m; MO (holo—3446424), VEN.

Ilex culmenicola Steyerm., Fieldiana Bot. 28(2): 322. 1952. *G. H. H. Tate 424*; 26 Nov.–16 Dec. 1928; Venezuela, T.F. Amazonas, Mt. Duida; 1,830–2,000 m; F, NY (holo).

Ilex davidsei Steyerm., Ann. Missouri Bot. Gard 75: 324. 1988. *G. Davidse 22719*; 23 July 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, lower part of the Río Baria; 80 m; MO (holo—3524657), VEN.

Ilex glabella Steyerm., Ann. Missouri Bot. Gard. 75: 324. 1988. *R. L. Liesner 16688*; 15–16 Mar. 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro de la Neblina, Camp 4; 780 m; MO (holo—3524663), VEN.

Ilex glaucophylla Steyerm., Bol. Soc. Venez. 15: 176. 1954. *L. Aristeguieta 2295*; June 1954; Venezuela, Miranda, Los Guayabitos; 1,200 m; F (holo), VEN.

Ilex gleasoniana Steyerm., Fieldiana Bot. 28(2): 322. 1952. *G. H. H. Tate 526*; 26 Nov.–16 Dec. 1928; Venezuela, T.F. Amazonas, Ridge 25, Mt. Duida; 2,000 m; F, NY (holo).

Ilex gransabanensis Steyerm., Ann. Missouri Bot. Gard. 75: 325. 1988. *T. Croat 54158a*; 26 July 1982; Venezuela, Bolívar, rd. from Ikabarú to Santa Elena, 16 mi. N of Ikabarú; 750 m; MO (holo—3524662), VEN.

Ilex guaiquinimae Steyerm., Ann. Missouri Bot. Gard. 75: 325. 1988. *J. A. Steyermark et al. 117276*; 24 May 1978; Venezuela, Bolívar, Cerro Guaiquiníma; 900 m; MO, VEN (holo).

Ilex holstii Steyerm., Ann. Missouri Bot. Gard. 75: 326. 1988. *J. A. Steyermark & B. Holst 130481*; 21–22, 24 Feb. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca, Sima Camp; 1,140 m; MO (holo—3446423), VEN.

Ilex ignicola Steyerm., Ann. Missouri Bot. Gard. 75: 326. 1988. *J. A. Steyermark et al. 130112*; 24–28 Feb. 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aratitiyope, 70 km SSW of Ocamo; 990–1,100 m; MO (holo—3226838), VEN.

Ilex jauaensis Steyerm., Ann. Missouri Bot. Gard. 75: 327. 1988. *J. A. Steyermark et al. 109294*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta de Jaua, Cerro Jaua, SW summit; 1,750–1,800 m; VEN (holo), MO (2582368).

Ilex karuaiana Steyerm., Fieldiana Bot. 28(2): 323. 1952. *J. A. Steyermark 60660*; 27 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo), NY.

Ilex liesneri Steyerm., Ann. Missouri Bot. Gard. 74: 94. 1987. *R. L. Liesner 18469*; 8–9 Mar. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca, 1–2 km N of Sima Camp; 1,100 m; MO (holo—3462076), VEN.

Ilex longipilosa Steyerm., Ann. Missouri Bot. Gard. 75: 327. 1988. *R. L. Liesner 19878*; 11 Nov. 1985; Venezuela, Bolívar, 3 km S of El Pauji, S slope and summit of El Abismo; 800–1,050 m; MO (holo—3446416), VEN.

Ilex magnifructa Edwin var. *minor* Steyerm., Ann. Missouri Bot. Gard. 75: 328. 1988. *F. Cardona 2943*; Feb. 1962; Venezuela, T.F. Amazonas, Cerro Ualipano; 1,760 m; MO, US (holo).

Ilex marahuacae Steyerm., Ann. Missouri Bot. Gard. 75: 328. 1988. *J. A. Steyermark & B. K. Holst 130425*; 21–22, 24 Feb. 1985; Venezuela, T.F. Amazonas, Cerro Marahuaca, Sima Camp; 1,140 m; MO (holo—3524661), VEN.

Ilex nervosa Triana var. *glabrata* Steyerm., Fieldiana Bot. 28(2): 324. 1952. *J. A. Steyermark 56653*; Venezuela, Mérida, above Tabay; 2,285–2,745 m; F (holo).

Ilex paruensis Steyerm., Ann. Missouri Bot. Gard. 75: 330. 1988. *O. Huber 4437*; 7 Oct. 1979; Venezuela, T.F. Amazonas, Dept. Atabapo, Serranía del Parú (Aroko); 1,100 m; VEN (holo).

Ilex paujiensis Steyerm., Ann. Missouri Bot. Gard. 75: 330. 1988. *R. Liesner & B. Holst 18796*; 19 Oct. 1985; Venezuela, Estado Bolívar, 3 km S of El Pauji; 900 m; MO (holo—3524660), VEN.

Ilex polita Steyerm., Ann. Missouri Bot. Gard. 75: 331. 1988. *G. Davidse & O. Huber 22679*; 25–27 Nov. 1982; Venezuela, Bolívar, Guayaraca, southern base, Auyán-tepui; 950 m; MO (holo—3524659), VEN.

Ilex ptariana Steyerm., Fieldiana Bot. 28(2): 324. 1952. *J. A. Steyermark 59574*; 30 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 2,285–2,405 m; F (holo), NY.

Ilex retusa Klotzsch f. *glabra* Steyerm., Fieldiana Bot. 28(4): 959. 1957. *J. A. Steyermark 58123*; 31 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,675 m; F (holo).

Ilex retusa Klotzsch f. *glaucescens* Steyerm., Fieldiana Bot. 28(4): 959. 1957. *J. A. Steyermark 58349*; 4 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,820–2,075 m; F (holo).

Ilex retusa Klotzsch f. *major* Steyerm., Fieldiana Bot. 28(4): 960. 1957. *J. A. Steyermark 58127*; 31 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,675 m; F (holo).

Ilex spathulata Steyerm., Ann. Missouri Bot. Gard. 75: 331. 1988. *R. L. Liesner 17599*; 17–18 Feb. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca; 12,250 m; MO (holo—3446415), VEN.

Ilex stenophylla Steyerm., Fieldiana Bot. 28(2): 325. 1952. *J. A. Steyermark 58038*; 26 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,095–1,520 m; F (holo), NY = *I. retusa* Klotzsch.

Ilex subrotundifolia Steyerm., Fieldiana Bot. 28(2): 328. 1952. *J. A. Steyermark 59394*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

Ilex summa Steyerm., Ann. Missouri Bot. Gard. 75: 332. 1988. *B. K. Holst 3617*; 26 Mar. 1987; Venezuela, Bolívar, Dist. Piar, Camarcaibarai-tepui, summit; 2,400 m; MO (holo—3446422), VEN.

Ilex tateana Steyerm., Fieldiana Bot. 28(2): 330. 1952. *J. A. Steyermark 58022*; 26 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,095–1,520 m; F (holo).

Ilex tepuiana Steyerm. ex Edwin, Mem. New York Bot. Gard. 12(3): 138. 1965. *J. A. Steyermark 60290*; 15–17 Nov. 1944; Venezuela, Bolívar, mesa between Ptari-tepui and Sororopan-tepui; 1,600 m; F (holo), NY.

Ilex venezuelensis Steyerm., Fieldiana Bot. 28(2): 330. 1952. *J. A. Steyermark 58340*; 4 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,820–2,075 m; F (holo).

Ilex vesparum Steyerm., Fieldiana Bot. 28(2): 332. 1952. *J. A. Steyermark 61659*; 21 Mar. 1945; Venezuela, Anzoátegui, above Santa Cruz; 2,000–2,300 m; F (holo).

Ilex wurdackiana Steyerm., Ann. Missouri Bot. Gard. 75: 332. 1988. *J. A. Steyermark & S. Nilsson 449*; 21 Apr. 1960; Venezuela, Bolívar, Cerro Venamo, NW slopes; 1,100–1,140 m; VEN (holo).

ARACEAE

Anthurium coibionii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 209. 1947. *J. A. Steyermark 42212*; 9 Jan. 1942; Guatemala, Dept. Zacapa, Río Sitio Nuevo, Sierra de las Minas; 1,200–1,500 m; F (holo) = *A. subcordatum* Schott, 1958.

Anthurium duidae Steyerm., Fieldiana Bot. 28(1): 92. 1951. *J. A. Steyermark 58099*; 31 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,675 m; F (holo) = *A. ptarianum* Steyerm., 1979.

Anthurium krauseanum Steyerm., Fieldiana Bot. 28(1): 93. 1951. *J. A. Steyermark 60847*; 4–5 Dec. 1944; Venezuela, Bolívar, SE base of Carrao-tepui; 1,460–1,615 m; F (holo).

Anthurium monsterioides Steyerm., Fieldiana Bot. 28(1): 93. 1951. *J. A. Steyermark 56727*; 23 May 1944; Venezuela, Bolívar, N of Mesa Bolívar, along Río Onia; 545–915 m; F (holo) = *A. clavigerum* Poepp. & Endl., 1979.

Anthurium ptarianum Steyerm., Fieldiana Bot. 28(1): 94. 1951. *J. A. Steyermark 59509*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo).

Anthurium radicosum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 210. 1947. *J. A. Steyermark 44776*; 6 Mar. 1942; Guatemala, Dept. Alta Verapaz, along Río Icvolay, N and NW of Finca Cubilquitz to Quebrada Diablo; 300–350 m; F (holo) = *A. pittieri* Engler, 1958.

Anthurium retiferum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 211. 1947. *J. A. Steyermark 48621*; 14 July 1942; Guatemala, Dept. Huehuetenango, Sierra de los Cuchumatanes, Cerro Huitz; 1,500–2,600 m; F (holo).

Anthurium titanium Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 211. 1947. *J. A. Steyermark 37963*; 16 Mar. 1940; Guatemala, Dept. San Marcos, Volcán Tajumulco along Río Cabús; 1,300–1,500 m; F (holo).

Monstera grandifolia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 212. 1947. *J. A. Steyermark 45423*; 28 Mar. 1942; Guatemala, Dept. Petén, between Finca Yalpemech and Chinajá; 50–100 m; F (holo).

Philodendron duidae Steyerm., Fieldiana Bot. 28(1): 96. 1951. *J. A. Steyermark 58225*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,025–1,200 m; F (holo) = *P. englerianum* Steyerm. subsp. *duidae* (Steyerm.) Bunting, 1988.

Philodendron englerianum Steyerm., Fieldiana Bot. 28(1): 96. 1951. *J. A. Steyermark 60863*; 5–6 Dec. 1944; Venezuela, Bolívar, Carrao-tepui; F (holo).

Philodendron krauseanum Steyerm., Fieldiana Bot. 28(1): 98. 1951. *J. A. Steyermark 60567*; 25 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma; 915–1,065 m; F (holo).

Philodendron ptarianum Steyerm., Fieldiana Bot. 28(1): 99. 1951. *J. A. Steyermark 59682*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo) = *P. callosum* subsp. *ptarianum* (Steyerm.) Bunting, 1988.

Philodendron rojasianum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 3. 1940. *J. A. Steyermark 33244*; Dec. 1939; Guatemala, Dept. Quezaltenango, Finca Pirineos, Volcán Santa María; 1,300–1,500 m; F (holo) = *P. guatemalense* Engler, 1958.

Philonotion williamsii Steyerm., Fieldiana Bot. 28(1): 99. 1951. *L. Williams 13922*; 23 Jan. 1942. Venezuela, T.F. Amazonas, Yavita; 128 m; F (holo) = *Schismatoglottis spruceana* (Schott) Bunting var. *williamsii* (Steyerm.) Bunting, 1988.

Schismatoglottis bolivariana Bunting & Steyerm., Brittonia 21(2): 187. 1969. *J. A. Steyermark 97811*; 17–29 Mar. 1967; Venezuela, Bolívar, del Río Kanarakuni, N and NE of Mision de Campamento Sanidad del Río Kanarakuni; 400 m; NY, VEN (holo).

Spathicarpa duidae Steyerm., Fieldiana Bot. 28(1): 101. 1951. *J. A. Steyermark 57994*; 25–26 Aug. 1944; Venezuela, T.F. Amazonas, Caño Negro, Cerro Duida; F (holo).

Stenospermation ammiticum Bunting, Bol. Soc. Venez. Ci. Nat. 25: 42. 1963. *J. A. Steyermark 89543*; 27 Aug. 1961; Venezuela, Bolívar, cabeceras de Río Chicanan; 500 m; BH, VEN (holo). Note: This is the accepted spelling of the genus.

Stenospermatium pittieri Steyerm., Fieldiana Bot. 28(1): 101. 1951. *J. A. Steyermark 57455*; 18 July 1944; Venezuela, Táchira, Alto de Lirio, between Bramon and Las Delicias; F (holo). Note: *Stenospermation* is the correct spelling for the genus.

Urospatha savannarum Steyerm., Fieldiana Bot. 28(1): 102. 1951. *J. A. Steyermark 57853*; 23 Aug. 1944; Venezuela, T.F. Amazonas, base of Cerro Duida, Sabana Grande; 200 m; F (holo) = *U. angustiloba* Engl., 1988.

ARALIACEAE

Dendropanax larensis Steyerm., Fieldiana Bot. 28(2): 441. 1952. *J. A. Steyermark 55434*; 11 Feb. 1944; Venezuela, Lara, between Buenos Aires and Páramo de las Rosas; 2,285–3,290 m; F (holo).

Dendropanax neblinae Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 82. 1984. *B. Maguire et al. 42062*; 14–16 Nov. 1957; Venezuela, T.F. Amazonas, just S of Camp 3, Cerro de la Neblina; 700 m; MO (3401817), NY (holo).

Dendropanax veillonii Steyerm., Pittieria 4: 9. 1972. *J.-P. Veillon 7*; 1971; Venezuela, Mérida, San Eusebio, La Carbonera; 2,350 m; VEN (holo).

Didymopanax auyantepuiensis Steyerm., Acta Bot. Venez. 2: 271. 1967. *J. A. Steyermark 93974*; 15 May 1964; Venezuela, Bolívar, Auyan-tepui; 2,050–2,300 m; VEN (holo) = *Schefflera auyantepuiensis* (Steyerm.) Maguire, Steyerm. & Frodin, 1984.

Didymopanax chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 456. 1967. *J. A. Steyermark 75788*; 20 June 1953; Venezuela, Bolívar, Apacara-tepui, Chimantá Massif; 2,000–2,150 m; NY (holo) = *Schefflera chimantensis* (Steyerm. & Maguire) Maguire, Steyerm. & Frodin, 1984.

Didymopanax multiramosus Steyerm., Acta Bot. Venez. 2: 273. 1967. *J. A. Steyermark 93926*; 15 May 1964; Venezuela, Bolívar, Auyan-tepui; 2,050–2,300 m; VEN (holo) = *Schefflera chimantensis* (Steyerm. & Maguire) Maguire, Steyerm. & Frodin, 1984.

Oreopanax capitatus (Jacq.) Decne. & Planch. var. *minor* Steyerm., Fieldiana Bot. 28(2): 442. 1952. *J. A. Steyermark 56242*; 3 May 1944; Venezuela, Mérida, between La Cumbre, San Jose and Mucutuy; 1,820–2,590 m; F (holo).

Oreopanax venezuelense Steyerm., Fieldiana Bot. 28(2): 442. 1952. *J. A. Steyermark 62017*; 11 Apr. 1945; Venezuela, Monagas, Cerro Guacharo; 1,100–1,300 m; F (holo).

Schefflera ayangannensis Maguire, Steyerm. & Frodin,

Mem. New York Bot. Gard. 38: 63. 1984. *S. S. Tillett et al. 45178*; 7 Aug. 1960; Guyana, Mt. Ayanganna; 900–1,100 m; NY (holo), VEN.

Schefflera coriacea subsp. *neblinae* Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 79. 1984. *N. T. Silva & U. Brazao 60903*; 26 Jan. 1966; Venezuela, Pirapucu, Serra da Neblina, Río Negro, Río Cauaburi, Río Maturaca; 1,300 m; NY (holo).

Schefflera cuatrecasasiana Steyerm., Fieldiana Bot. 28(2): 443. 1952. *J. A. Steyermark 57336*; 15 July 1944; Venezuela, Táchira, base of Páramo de Tamá, 4–10 km above Betania; 2,500–2,895 m; F (holo).

Schefflera duidae Steyerm., Fieldiana Bot. 28(2): 444. 1952. *J. A. Steyermark 57989*; 25–26 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 305–1,095 m; F (holo).

Schefflera globulifera Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 69. 1984. *B. Maguire et al. 37354*; 23 Jan. 1954; Venezuela, T.F. Amazonas, Cerro de la Neblina, Cumbre Camp; 1,700–2,000 m; NY (holo).

Schefflera gracillima Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 371. 1976. *J. A. Steyermark et al. 109373*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,750–1,800 m; NY, VEN (holo).

Schefflera guanayensis Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 66–67. 1984. *B. Maguire et al. 31740*; 2 Feb. 1951; Venezuela, T.F. Amazonas, Cerro Guanay; 1,800 m; NY (holo).

Schefflera guanayensis Maguire, Steyerm. & Frodin subsp. *paruensis* Maguire, Steyerm. & Frodin, New York Bot. Gard. 38: 67. 1984. *R. S. Cowan & J. J. Wurdack 31405*; 12 Feb. 1951; Venezuela, T.F. Amazonas, Cerro Parú, Serranía Parú; NY (holo).

Schefflera guanayensis Maguire, Steyerm. & Frodin subsp. *sipapoensis* Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 67. 1984. *B. Maguire & L. Politi 27756*; 17 Dec. 1948; Venezuela, T.F. Amazonas, Cerro Sipapo (Paraque), Phelps Camp to N Savanna; 1,400 m; MO (3401819), NY (holo).

Schefflera huachamacarii Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard 38: 76. 1984. *B. Maguire et al. 30253*; 15 Dec. 1950; Venezuela, T.F. Amazonas, Cerro Huachamacari, vicinity of Summit Camp; 1,620 m; NY (holo).

Schefflera monosperma Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 51. 1984. *I. Thurn 162*; Venezuela, Roraima; K (holo).

Schefflera pallens Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 72. 1984. *B. Maguire et al. 60503*; 3 Dec. 1965; Brazil, Amazonas, trail to Pico Phelps, Serra de Neblina; 2,425 m; NY (holo).

Schefflera pauciradiata Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 74. 1984. *B. Maguire & L. Politi 28454*; Venezuela, T.F. Amazonas, Cerro Sipapo, Upper E Basin; 1,900 m; NY (holo).

Schefflera pedicelligera Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 63. 1984. *B. Maguire et al. 29546*; 19 Nov. 1950; Venezuela, T.F. Amazonas, Culebra Creek drainage, Río Cununcunuma, Cerro Duida; 1,500 m; NY (holo).

Schefflera pimichinensis Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 55. 1984. *B. Maguire & J. J. Wurdack 35635*; 14 Apr. 1953; Venezuela, T.F. Amazonas, Sabana El Venado, left bank of Caño Pimichin, above Puerto Pimichin; 140 m; NY (holo), VEN.

Schefflera plurispicata Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 52. 1984. *N. T. Silva & U. Brazao 60941*; 29 Jan. 1966; Brazil, Amazonas, Serra Pirapucu, Serra da Neblina; MG, NY (holo).

Schefflera quinquecarinata Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 44. 1963. *J. A. Steyermark & S. Nilsson 483*; 23 Apr. 1960; Venezuela, Bolívar, headwaters of Río Cuyuni; 1,300 m; VEN (holo).

Schefflera quinquestylorum Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 46. 1963. *J. A. Steyermark & S. Nilsson 429*; 21 Apr. 1960; Venezuela, Bolívar, Cerro Venamo; 1,100–1,140 m; VEN (holo) = *S. duidae* Steyerm. subsp. *quinquestylorum* (Steyerm.) Maguire, Steyerm. & Frodin, 1984.

Schefflera reticulata (Gleason) Maguire, Steyerm. & Frodin subsp. *jauaensis* Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 59. 1984. *J. A. Steyermark 98078*; 22–27 Mar. 1967; Venezuela, Estado Bolívar, Meseta de Jaua; 1,922–2,100 m; NY (holo), VEN.

Schefflera reticulata (Gleason) Maguire, Steyerm. & Frodin subsp. *yutajensis* Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 59. 1984. *B. Maguire & C. K. Maguire 35154*; 11 Feb. 1953; Venezuela, T.F. Amazonas, Serranía Yutaje, Río Manapiare; NY (holo).

Schefflera rugosifolia Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 71. 1984. *McConnell & Quelch 663*; Venezuela, Bolívar, Mt. Roraima; K (holo).

Schefflera simplex Steyerm. & Holst, Ann. Missouri Bot. Gard. 75: 1082. 1988. *A. Gentry & B. Stein 46694*; 17 Apr. 1984; Venezuela, T.F. Amazonas, Cerro de la Neblina; 1,900–2,100 m; MO (holo—348100), VEN.

Schefflera sipapoensis Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 59. 1984. *B. Maguire & L. Politi 28471*; 20 Jan. 1949; Venezuela, T.F. Amazonas, Cerro Sipapo (Paraque), Upper E Basin; 1,500–1,650 m; NY (holo).

Schefflera tamana Steyerm., Fieldiana Bot. 28(2): 444. 1952. *J. A. Steyermark 57321*; 15 July 1944; Venezuela, Táchira, base of Páramo de Tamá, 4–10 km above Betania; 2,500–2,895 m; F (holo).

Schefflera tamatamaensis Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 55. 1984. *J. J. Wurdack & L. S. Adderley 43148*; 23 June 1959; Venezuela, T.F. Amazonas, Caño Tama Tama, just above Tama—Tama, right bank Río Orinoco; 150 m; K, MG, NY (holo), US, VEN.

Schefflera tremuloidea Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 61. 1984. *B. Maguire et al. 42379*; 13 Dec. 1957; Venezuela, T.F. Amazonas, Summit, Cerro Neblina, E escarpment of upper Cañon Grande Basin; 2,000 m; NY (holo), MO (2911090, 3401829), VEN.

Schefflera tremuloidea Maguire, Steyerm. & Frodin var. *marahuacensis* Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 63. 1984. *J. A. Steyermark et al. 124406*; 16 Feb. 1981; Venezuela, T.F. Amazonas, Cerro Marahuaca; 2,500 m; MO, NY (holo), US, VEN.

Schefflera umbellata (N.E. Br.) Viguier subsp. *duidana* Maguire, Steyerm. & Frodin, Mem. New York Bot. Gard. 38: 74. 1984. *G. H. H. Tate 431*; 16 Dec. 1928; Venezuela, T.F. Amazonas, Cerro Duida, summit, slopes of ridge; 1,650–1,800 m; NY (holo).

Schefflera yutajensis Steyerm. & Holst, Ann. Missouri Bot. Gard. 75: 1082. 1988. *B. K. Holst & R. L. Liesner 3426*; 11 Mar. 1987; Venezuela, T.F. Amazonas, Dept. Atures, valley of Río Coro-Coro, W of

Serranía de Yutaje; 1,100 m; MO (holo—3485098), MO.

ARECACEAE

Asterogyne yaracuyense Henderson & Steyerm., Brittonia 38: 309. 1986. *J. A. Steyermark et al. 100311*; 9–10 Nov. 1967; Venezuela, Yaracuy, Cerro de Chapa; 1,200–1,400 m; BH (holo), VEN.

Bactris bergantina Steyerm., Fieldiana Bot. 28(1): 71. 1951. *J. A. Steyermark 61039*; 20 Feb. 1945; Venezuela, Anzoátegui, NE of Bergantin, tributary to Río Neveri, along Río Leon by Quebrada Danta; 500 m; F (holo).

Bactris duidae Steyerm., Fieldiana Bot. 28(1): 73.1951. *J. A. Steyermark 57908*; 23 Aug. 1944; Venezuela, T.F. Amazonas, near Base River (Caño Negro) at SE base of Cerro Duida; 215 m; F (holo).

Bactris kamarupa Steyerm., Fieldiana Bot. 28(1): 75. 1951. *J. A. Steyermark 60542*; 25 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma, tributary of Río Pacairao, below Santa Teresita de Kavanayen; 915–1,065 m; F (holo).

Bactris ptariana Steyerm., Fieldiana Bot. 28(1): 77. 1951. *J. A. Steyermark 60046*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Bactris sororopanae Steyerm., Fieldiana Bot. 28(1): 78. 1951. *J. A. Steyermark 60781*; 29 Nov. 1944; Venezuela, Bolívar, along Río Karuai, base of Sororopan-tepui, W of La Laja; 1,220 m; F (holo).

Bactris venezuelensis Steyerm., Fieldiana Bot. 28(1): 80. 1951. *J. A. Steyermark 57933*; 23 Aug. 1944; Venezuela, T.F. Amazonas, SE base of Cerro Duida, along Base River (Caño Negro); 225 m; F (holo).

Chamaedorea aequalis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(50): 196. 1947. *J. A. Steyermark 51666*; 31 Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Negro; 1,600–2,080 m; F (holo).

Chamaedorea aguilariana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 197. 1947. *P. C. Standley 86890*; 9 Feb. 1941; Guatemala, Dept. Quezaltenango, between Finca Pirineos and Patzulín; 1,200–1,400 m; F (holo).

Chamaedorea brachypoda Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 198. 1947. *J. A. Steyermark 39185*; 9 Apr. 1940; Guatemala, Dept. Izabal, between Bananera and La Presa, base of Sierra del Mico; 150 m; F (holo).

Chamaedorea carchensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 199. 1947. *P. C. Standley 90160*; Mar. 1941; Guatemala, Dept. Verapaz, along Río Carchá, between Cobán and San Pedro Carchá; 1,350 m; F (holo).

Chamaedorea digitata Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 200. 1947. *J. A. Steyermark 51683*; 31 Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Negro; 1,600–2,000 m; F (holo).

Chamaedorea fusca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 201. 1947. *J. A. Steyermark 38123*; 28 Mar. 1940; Guatemala, Dept. Izabal, Sierra del Mico; 300 m; F (holo).

Chamaedorea nubicum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 202. 1947. *J. A. Steyermark 43583a*; 5 Feb. 1942; Guatemala, Dept. El Progreso, Sierra de las Minas; 2,900 m; F (holo).

Chamaedorea pachecoana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 203. 1947. *P. C. Standley 63104*; 20 Jan. 1939; Guatemala, Dept. Guatemala, cultivated, said to come from Dept. Totonicapan, but probably from some other part of the Occidente; F (holo).

Chamaedorea quezalteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 204. 1947. *P. C. Standley 87159*; 9 Feb. 1941; Guatemala, Dept. Quezaltenango, between Finca Pirineos and Patzulín; 1,200–1,400 m; F (holo).

Chamaedorea rojasiana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 205. 1947. *J. A. Steyermark 33479*; 1–2 Jan. 1940; Guatemala, Dept. Quezaltenango, Quebrada San Gerónimo, Finca Pirineos, Volcán Santa María; 1,300–2,000 m; F (holo).

Chamaedorea skutchii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 206. 1947. *A. F. Skutch 935*; 4 Aug. 1934; Guatemala, Dept. Quezaltenango, Volcán Zunil; 2,400 m; F (holo).

Chamaedorea stenocarpa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 206. 1947. *J. A. Steyermark 41893*; 25 Dec. 1941; Guatemala, Dept. Izabal, Cerro San Gil; 650–900 m; F (holo).

Chamaedorea stricta Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 207. 1947. *J. A. Steyermark 37381*; 9 Mar. 1940; Guatemala, Dept. San Marcos, Volcán Tajumulco, up Cerro de Mono; 1,400–1,700 m; F (holo).

Chamaedorea vulgata Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 208. 1947. *J. A. Steyermark 37735*; 14 Mar. 1940; Guatemala, Dept. San Marcos, Volcán Tajumulco, 9 mi. NW of El Porvenir; 1,300–2,000 m; F (holo).

Dahlgrenia Steyerm., Fieldiana Bot. 28(1): 82. 1951, gen. nov.

Dahlgrenia ptariana Steyerm., Fieldiana Bot. 28(1): 82. 1951. *J. A. Steyermark 60044*; 10–11 Nov. 1944; Venezuela, Bolívar, SE facing slopes of Ptari-tepui; 1,585–1,600 m; F (holo) = *Dictyocaryum ptariense* (Steyerm.) Moore & Steyerm., 1967.

Desmoncus duidensis Steyerm., Fieldiana Bot. 28(1): 85. 1951. *J. A. Steyermark 57944*; 23 Aug. 1944; Venezuela, T.F. Amazonas, SE base of Cerro Duida, along Base River (Caño Negro); 225 m; F (holo).

Desmoncus multijugus Steyerm., Fieldiana Bot. 28(1): 85. 1951. *J. A. Steyermark 60968*; 18 Dec. 1944; Venezuela, Bolívar, Tumeremo; 305 m; F (holo).

Euterpe ptariana Steyerm., Fieldiana Bot. 28(1): 87. 1951. *J. A. Steyermark 60045*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Geonoma karuaiana Steyerm., Fieldiana Bot. 28(1): 88. 1951. *J. A. Steyermark 60789*; 29 Nov. 1944; Venezuela, Bolívar, W of La Laja, base of Sororopan-tepui, along Río Karuai; 1,220 m; F (holo).

Hyospathe maculata Steyerm., Fieldiana Bot. 28(1): 89. 1951. *J. A. Steyermark 60406*; 20–21 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma, between Santa Teresita de Kavanayen and Río Pacairao (tributary of Río Mouak); 1,065–1,220 m; F (holo).

Mauritia flexuosa L. var. *venezuelana* Steyerm., Fieldiana Bot. 28(1): 90. 1951. *J. A. Steyermark 57649*; 2 Aug. 1944; Venezuela, Bolívar, between Río Caroni and Ciudad Bolívar; 200 m; F (holo).

Prestoea humilis Henderson & Steyerm., Brittonia 38: 311. 1986. *A. Henderson 501*; 12 Nov. 1985; Venezuela, Yaracuy, Cerro la Chapa; 1,200–1,400 m; K, MYF, NY, VEN (holo).

Socratea albolineata Steyerm., Fieldiana Bot. 28(1): 91.

1951. *J. A. Steyermark 60541*; 25 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma, tributary Río Pacairao, below Santa Teresita de Kavanayen; 915–1,065 m; F (holo).

ARISTOLOCHIACEAE

Aristolochia mollis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 155. 1944. *J. A. Steyermark 51269*; 24 Aug. 1942; Guatemala, Dept. Huehuetenango, canyon tributary to Río Trapichillo, between Democracia and canyon of Chamushú; 1,000 m; F (holo) = *A. paracleta* Pfeiffer, nom. nov.

ASCLEPIADACEAE

Asclepias woodsoniana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 224. 1947. *J. A. Steyermark 31781*; 15 Nov. 1939; Guatemala, Dept. Jutiapa, between Trapiche Vargas and Asunción Mita; 500 m; F (holo).

Blepharodon auyantepuiense Steyerm., Acta Bot. Venez. 2: 319. 1967. *J. A. Steyermark 93889*; 14 May 1964; Venezuela, Bolívar, Auyan-tepui; 2,000–2,200 m; VEN (holo).

Cynanchum auyantepuiense Steyerm., Acta Bot. Venez. 2: 320. 1967. *J. A. Steyermark 93892*; 14 May 1964; Venezuela, Bolívar, Auyan-tepui; 2,050 m; VEN (holo).

Cynanchum stenomeres Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 224. 1947. *W. A. Schipp 674*; 5 Feb. *s.n.*; Belize, All Pines; sea level; F (holo).

Marsdenia blepharodes Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 226. 1947. *J. A. Steyermark 33615*; 6 Jan. 1940; Guatemala, Dept. Quezaltenango, San Juan Patzulín 1,500 m; F (holo).

ASTERACEAE

Achnopogon Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 437. 1957, gen. nov.

Achnopogon virgatus Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 438. 1957. *J. A. Steyermark & J. J. Wurdack 681*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,090 m; F (holo), NY.

Ageratum chortianum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 98. 1944. *J. A. Steyermark 31269*; Nov. 1939; Guatemala, Dept. Chiquimula, Montaña Castilla, near Montaña Cebollas, along Río Santa Lucía Saso; 1,200–1,500 m; F (holo).

Alomia ballotifolia Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 425. 1957. *J. A. Steyermark 75520*; 21 May 1953; Venezuela, Bolívar, Chimantá Massif, Chimantá-tepui (Torono-tepui); 1,700 m; F (holo), NY.

Aphanactis standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 390. 1940. *P. C. Standley 58674*; 4 Dec. 1938; Guatemala, Dept. Chimaltenango, Cerro Tecpán, Santa Elena; 2,700 m; F (holo).

Aplopappus gymnocephalus DC. f. *albus* Steyerm. & Moore, Ann. Missouri Bot. Gard. 20: 797. 1933. *J. A. Moore & J. A. Steyermark 3488*; 17 July 1931; U.S.A., Texas, Culberson Co., Guadalupe Mountains, ridge above McKittrick Canyon; MO (holo) = *Haplopappus gymnocephalus* DC.

Archibaccharis blakeana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 296. 1940. *P. C. Standley 58597*; 1938–1939; Guatemala, Dept. Sacatepéquez, near Antigua; 1,500–1,600 m; F (holo).

Aspilia avilensis Aristeg. & Steyerm., Fl. Venez. 10(2): 552. 1964. *C. Vogl 41*; Aug. 1937; Venezuela, Distr. Federal, Caracas, Serranías del Avila; depository not indicated.

Oyedaea verbesinoides DC. var. *hypomalaca* Steyerm., Fieldiana Bot. 28(3): 664. 1953. *J. A. Steyermark 62095*; 15 Apr. 1945; Venezuela, Monagas, Cerro Negro; 1,500–2,180 m; F (holo).

Pectis flava Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 106. 1944. *J. A. Steyermark 30415*; 24 Oct. 1939; Guatemala, Dept. Jutiapa, along railroad between Agua Blanca and Amatillo; 950–990 m; F (holo) = *P. uniaristata* DC. var. *holostemma* A. Gray, 1976.

Pectis venezuelensis Steyerm., Fieldiana Bot. 28(3): 666. 1953. *J. A. Steyermark 57528*; 31 July 1944; Venezuela, Bolívar, 5 km W of Upata; 500 m; F (holo).

Perymenium inamoenum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 143. 1944. *J. A. Steyermark 29737*; Oct. 1939; Guatemala, Dept. Zacapa, Sierra de las Minas, Finca Alejandria; 1,000–1,500 m; F (holo).

Perymenium jalapanum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 144. 1944. *J. A. Steyermark 32658*; Guatemala, Dept. Jalapa, between Muramundo and summit of Montaña Miramundo; 2,000–2,300 m; F (holo).

Piptocarpha jauaensis Aristeg. & Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 402. 1976. *J. A. Steyermark et al. 109485*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,800 m; F (holo).

Polymnia meridensis Steyerm., Fieldiana Bot. 28(3): 667. 1953. *J. A. Steyermark 57519*; 22 July 1944; Venezuela, Mérida, below Chachopo; 3,045 m; F (holo).

Polymnia standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 106. 1944. *J. A. Steyermark 36181*; 20 Feb. 1940; Guatemala, Dept. San Marcos, between La Vega Ridge along Río Vega, Volcán Tacaná; 2,500–3,000 m; F (holo) = *Rumfordia standleyi* (Steyerm.) Standl. & Steyerm., 1947.

Polymnia verapazensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 144. 1944. *H. von Tuerckheim II.1732*; Apr. 1907; Guatemala, Dept. Baja Verapaz, Pansal; 1,000 m; F (holo) = *Rumfordia guatemalensis* (Coult.) S. F. Blake, 1976.

Quelchia bracteata Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 435. 1957. *J. A. Steyermark & J. J. Wurdack 683*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 1,970 m; NY (holo), F.

Quelchia cardonae Steyerm., Fieldiana Bot. 28(3): 670. 1953. *F. Cardona 2288*; Oct. 1947; Venezuela, Bolívar, Cerro Acopan, Río Caroni; 2,200 m; F (holo).

Quelchia eriocaulis Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 435. 1957. *J. A. Steyermark & J. J. Wurdack 675*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,165–2,180 m; F (holo), NY.

Quelchia ×*grandifolia* Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 436. 1957. *J. A. Steyermark & J. J. Wurdack 756*; 12 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,185 m; F (holo).

Rojasianthe Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 411. 1940, gen. nov.

Rojasianthe superba Standl. & Steyerm., Field Mus. Nat. Hist., Bot Ser. 22(4): 315. 1940. *J. A. Steyermark 35835*; 16 Feb. 1940; Guatemala, Dept. San Marcos, Volcán Tajumulco; 3,300–3,900 m; F (holo).

Rudbeckia hirta L. f. *homochroma* Steyerm., Rhodora 40: 179. 1938. *J. A. Steyermark 11345*; 3 July 1936; U.S.A., Missouri, Oregon Co., 10 mi. W of New Liberty, Fristoe Purchase Unit, Clark National Forest; MO (holo).

Sabazia urticifolia (H.B.K.) DC. var. *venezuelensis* Steyerm., Fieldiana Bot. 28(3): 672. 1953. *J. A. Steyermark 55379*; 8 Feb. 1944; Venezuela, Lara, between Santo Domingo and Los Quebraditos, above Humocaro Bajo; 2,430–2,475 m; F (holo).

Salmea orthocephala Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 145. 1944. *P. C. Standley 59321*; 8 Dec. 1938; Guatemala, Dept. Guatemala, Concuá Bridge over Río Motagua; 300 m; F (holo).

Schaetzellia standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 107. 1944. *J. A. Steyermark 32041*; 26 Nov. 1939; Guatemala, Dept. Jutiapa, Laguna Retzana; 600 m; F (holo) = *Macvaughiella standleyi* (Steyerm.) King & Robs., 1976.

Schkuhria viscosissima Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 318. 1940. *P. C. Standley 62513*; 12–14 Jan. 1939; Guatemala, Dept. Quiché, near Sacapulas; 1,040–1,240 m; F (holo) = *Florestina pedata* (Cav.) Cassini, 1976.

Siegesbeckia nudicaulis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 262. 1947. *J. A. Steyermark 50114*; 5 Aug. 1942; Guatemala, Dept. Huehuetenango, Sierra de los Cuchumatanes, above San Juan Ixcoy; 2,800–3,400 m; F (holo).

Silphium perfoliatum L. f. *petiolatum* Palmer & Steyerm., Brittonia 10: 119. 1958. *J. A. Steyermark 80474*; 19 Oct. 1955; U.S.A., Missouri, Stone Co., above White River, along S and E side at base of N and NW facing wooded slopes, NE and SW of Mill Creek, 4 air mi. SW of Radical, 4.5–5 mi. NE of Baxter; F (holo).

Silphium terebinthinaceum Jacq. var. *lucy-brauniae* Steyerm., Rhodora 53: 134. 1951. *E. L. Braun s.n.*; 17 Aug. 1950; U.S.A., Ohio, Adams Co., 2.5 mi. N of Ohio route 348, N part of Jefferson Top, SE of Scrub Ridge; Herb. Braun (holo).

Soliva anthemidifolia R. Br. var. *lanuginosa* Steyerm., Fieldiana Bot. 28(3): 672. 1953. *J. A. Steyermark 55506*; 12 Feb. 1944; Venezuela, Lara, between Buenos Aires to Canyon of El Callado; 2,285–2,740 m; F (holo).

Stenopadus affinis Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 427. 1957. *J. A. Steyermark 75110*; 18 Apr. 1953; Venezuela, Bolívar, Chimantá Massif, Abacapa-tepui; 850–1,100 m; F (holo), NY.

Stenopadus chimantensis Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 1957. *J. A. Steyermark & J. J. Wurdack 652*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,165–2,180 m; NY (holo), F.

Stenopadus colombianus Cuatr. & Steyerm., Bot. Mus. Leafl. 17(3): 99. 1955. *R. E. Schultes & I. Cabrera 15031*; 23–25 Jan. 1952; Colombia, Comisaria del Vaupés, Río Kananari, Cerro Isibukuri, near summit; F (holo).

Stenopadus talaumifolius S. F. Blake var. *magnifolius* Steyerm., Fieldiana Bot. 28(3): 673. 1953. *F. Cardona 2190*; Sep. 1947; Venezuela, Bolívar, Cerro Arepuchi; 600 m; US (holo).

Stevia chortiana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 108. 1944. *J. A. Steyermark 30866*; Oct. 1939; Guatemala, Dept. Chiquimula, between Finca San Jose and Montaña Nube; 1,200–1,700 m; F (holo) = *S. hirsuta* var. *chortiana* (Standl. & Steyerm.) Grashoff, 1974.

Stevia vulcanicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 27. 1943. *J. A. Steyermark 34757*; Jan. 1940; Guatemala, Dept. Quezaltenango, Volcán Santo Tomás; 2,500–3,700 m; F (holo) = *S. microchaeta* Schultz-Bip., 1976.

Stomatochaeta colveei Steyerm., Brittonia 32: 21. 1980. *J. A. Steyermark et al. 117407*; 26 May 1978; Venezuela, Bolívar, Cerro Guaiquinima; VEN (holo).

Tagetes sororia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 146. 1944. *P. C. Standley 85228*; 29 Jan. 1941; Guatemala, Dept. Quezaltenango, N of Olintepeque; 2,500–2,800 m; F (holo) = *T. nelsonii* Greenm., 1976.

Trixis amphimalaca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 147. 1944. *P. C. Standley 82538*; 6 Jan. 1941; Guatemala, Dept. Huehuetenango, N of Chiantla; 2,000–2,250 m; F (holo) = *T. nelsonii* Greenm., 1976.

Verbesina agricolarum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 319. 1940. *J. R. Johnston 1026*; 21 Sep. 1937; Guatemala, Dept. Chimaltenango, Finca La Alameda; F (holo).

Verbesina angusta Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 9(3): 426. 1957. *J. A. Steyermark & J. J. Wurdack 851*; 13 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,120 m; F, NY (holo).

Verbesina apleura S. F. Blake var. *foliolata* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 109.

1944. *P. C. Standley 67540*; Mar. 1939; Guatemala, Dept. Quezaltenango, Volcán Santa María; 2,700 m; F (holo) = *V. apleura* S. F. Blake var. *apleura*, 1976.

Verbesina blakeana Steyerm., Fieldiana Bot. 28(3): 674. 1953. *J. A. Steyermark 56300*; 4 May 1944; Venezuela, Mérida, between Mucutuy and Mucuchachi; 1,065–2,430 m; F (holo).

Verbesina calciphila Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 262. 1947. *J. A. Steyermark 50132*; 6 Aug. 1942; Guatemala, Dept. Huehuetenango, Sierra de los Cuchumatanes; 3,700 m; F (holo).

Verbesina exalata Steyerm., Fieldiana Bot. 28(3): 675. 1953. *J. A. Steyermark 55176*; 5 Jan. 1944; Venezuela, Distr. Federal, above Caracas, Cordillera del Avila; 1,065–1,520 m; F (holo) = *V. turbacensis* H.B.K., 1964.

Verbesina guatemalensis Robinson & Greenmann var. *glabrata* Standl. & Steyerm., Field Mus. Bot. Ser. 23(2): 109. 1944. *J. A. Steyermark 29505*; Oct. 1939; Guatemala, Dept. Zacapa, Sierra de las Minas; 250–900 m; F (holo) = *V. guatemalensis* H. Robinson & Greenmann var. *guatemalensis*, 1976.

Verbesina minarum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 263. 1947. *J. A. Steyermark 42489*; 12–13 Jan. 1942; Guatemala, Dept. Zacapa, Sierra de las Minas, Río Repollal; 2,100–2,400 m; F (holo).

Verbesina negrensis Steyerm., Fieldiana Bot. 28(3): 675. 1953. *J. A. Steyermark 57066*; 7 July 1944; Venezuela, Mérida, between Barladores and Páramo de la Negra; 2,285–2,430 m; F (holo).

Verbesina petzalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 147. 1944. *P. C. Standley 82921*; 9 Jan. 1941; Guatemala, Dept. Huehuetenango, near crossing of Río San Juan Ixtán, E of San Rafael Petzal;. 1,730 m; F (holo).

Verbesina tachirensis Steyerm., Fieldiana Bot. 28(3): 677. 1953. *J. A. Steyermark 57149*; 12 July 1944; Venezuela, Táchira, between Las Delicias and Paraguita, bordering Río Táchira; 1,675–1,890 m; F (holo).

Vernonia baldwinii Torr. f. *albiflora* Steyerm., Brittonia 10: 118. 1958. *E. J. Palmer 61259*; 7 Sep. 1955; U.S.A., Missouri, Lawrence Co., along Turnback Creek and U.S. Hwy. 166, 3.5 mi. E of Chesapeake; F (holo).

Vernonia corae Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 395. 1940. *J. A. Steyermark 36787*; 27 Feb. 1940; Guatemala, Dept. San Marcos, Volcán Tajumulco; 1,800–2,500 m; F (holo).

Veronia medialis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 148. 1944. *P. C. Standley 87473*; 17 Feb. 1941; Guatemala, Dept. Retalhuleu, Río Coyote, along road 4 km W of Tetalhuleu; 300 m; F (holo) = *V. arborescens* (L.) Sw., 1982.

Vernonia mima Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser 23(5): 264. 1947. *P. C. Standley 82871*; 9 Jan. 1941; Guatemala, Dept. Huehuetenango, near crossing of Río San Juan Ixtán, E of San Rafael Petzal; 1,730 m; F (holo).

Vernonia missurica Raf. f. *swinkii* Steyerm., Rhodora 59: 24. 1957. *F. A. Swink 2775*; 11 Aug. 1955; U.S.A., Illinois, Cook Co., prairie S of 95th St. and W of Hwy. 45, Argonne Forest Preserve S of Willow Springs; F (holo).

Viguiera shrevei Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 421. 1938. *F. Shreve 8035*; 26 July 1937; Mexico, Chihuahua, near San Juanito, Distr. Bocoyna; 2,400 m; F (holo).

Zexmenia pinetorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 149. 1944. *P. C. Standley 75590*; 28 Oct. 1940; Guatemala, Dept. Jutiapa, below Jutiapa and Plan de Urrutia; 900–1,200 m; F (holo) = *Wedelia pinetorum* (Standl. & Steyerm.) Becker, 1975.

BALSAMINACEAE

Impatiens pallida Nutt. f. *dichroma* Steyerm., Rhodora 40: 179. 1938. *J. A. Steyermark 25927*; 6 Sep. 1937; U.S.A., Missouri, Pike Co., Mississippi River, 1.5 mi. NW of Louisiana; MO (holo).

BERBERIDACEAE

Berberis johnstonii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 140. 1940. *J. R. Johnston 1525*; 14 Dec. 1938; Guatemala, Dept. Sacatepéquez, Parramos; F (holo) = *Mahonia johnstonii* (Standl. & Steyerm.) Standl. & Steyerm., 1943.

Mahonia volcania Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 6. 1943. *P. C. Standley 65221*; Feb. 1939; Guatemala, Volcán de Agua, above Santa María de Jesús; 3,000 m; F (holo).

Podophyllum peltatum L. f. *biltmoreanum* Steyerm., Rhodora 54: 134. 1952. *V. Bordener & C. Steyermark s.n.*; 16 Aug. 1950; U.S.A., Illinois, Lake Co., Biltmore Estates, S of Eaton Rd. and W of Kimberly Rd., 5 mi. N of Barrington; F (holo).

BETULACEAE

Corylus americana Walt. f. *indehiscens* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 516. 1935. *B. F. Bush 10332*; 5 Sep. 1924; U.S.A., Missouri, Jackson Co., Greenwood; GH (holo).

BIGNONIACEAE

Pseudocalymma standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 236. 1947. *J. A. Steyermark 33533*; 5 Jan. 1940; Guatemala, Dept. Quezaltenango, Finca Pirineos and Finca Soledad, Volcán Santa María; 1,300–1,400 m; F (holo) = *Mansoa standleyi* (Steyerm.) A. Gentry, 1982.

BOMBACACEAE

Catostemma clarkii Steyerm., Ann. Missouri Bot. Gard. 74: 638. 1987. *H. A. Clark 8126*; 19 Aug. 1981; Venezuela, T.F. Amazonas, 10.8 km NE of San Carlos on road to Solano; 119 m; MO (holo).

Catostemma ebracteolatum Steyerm., Ann. Missouri Bot. Gard. 74: 641. 1987. *B. Maguire & L. Politi 2874*; 2 Feb. 1949; Venezuela, T.F. Amazonas, Cerro Sipapo (Paráque), water course above Intermediate Camp; MO (holo), NY.

Catostemma hirsutulum Steyerm., Ann. Missouri Bot. Gard. 74: 642. 1987. *J. A. Steyermark 74781*; 30–31 Mar. 1953; Venezuela, Bolívar, Chimantá Massif, NW slopes Abácapa, vicinity of camp 1 along Río Abácapa-tepui; F, MO (holo), VEN.

Catostemma marahuacensis Steyerm., Ann. Missouri Bot. Gard. 74: 643. 1987. *J. A. Steyermark & B. Holst 130878*; 28 Feb.–1 Mar. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca, 'Sima Camp' south central portion Caño Negro; 1,140 m; MO (holo—3327355).

Catostemma pubistylum Steyerm., Ann. Missouri Bot. Gard. 74: 643. 1987. *H. L. Clark & P. Maquirino 6742*; 3 Aug. 1978; Venezuela, T.F. Amazonas, IVIC

main study site, 4.3 km NE of San Carlos de Río Negro; 119 m; NY (holo).

Catostemma sancarlosiana Steyerm., Ann. Missouri Bot. Gard. 74: 644. 1987. *H. L. Clark & K. Clark 8117*; 16 Aug. 1981; Venezuela, T.F. Amazonas, 10.8 km NE of San Carlos on Solano Road; 119 m; MO (holo—3142831).

Pochota aracamuniana Steyerm., Ann. Missouri Bot. Gard.: in press. 1989. *R. L. Liesner & G. Carnevali 22559*; 28 Oct. 1987; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp; 1,400 m; MO (holo), VEN.

Pochota ewelii Steyerm., Ann. Missouri Bot. Gard. 75: 1077. 1988. *J. Ewel 135*; 23 Apr. 1964; Brazil, Dept. Amazonas, near Venezuela frontier, camino al Cerro Neblina desade Río Tucano; 1,250 m; MY (holo).

Pochota fuscolepidota Steyerm., Ann. Missouri Bot. Gard. 75: 1077. 1988. *R. L. Liesner 18452*; 8–9 Mar. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca; 1,100 m; MO (holo—3483071), VEN.

Pochota gracilis (Robyns) Steyerm., subsp. *bolivarensis* Steyerm., Ann. Missouri Bot. Gard. 75: 1078. 1988. *J. A. Steyermark 98206*; 17–29 Mar. 1967; Venezuela, Bolívar, Río Kanarakuni, southern base of Cerro Sarisariñama, Meseta de Jaua; 400 m; NY, VEN (holo).

Pochota liesneri Steyerm., Ann. Missouri Bot. Gard. 75: 1079. 1988. *R. L. Liesner 18637*; 14 Mar. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Salto Yureba, Cerro Yureba, lower Ventuari; 350 m; MO (holo—3483072), VEN.

Pochota mawarinumae Steyerm., Ann. Missouri Bot. Gard. 75: 1079. 1988. *R. L. Liesner 16355*; 2 Mar. 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, near Cerro de la Neblina Base Camp, Río Mawarinuma; 140 m; MO (holo—3483069, 3483068), VEN.

Pochota redmondii Steyerm., Ann. Missouri Bot. Gard. 75: 1081. 1988. *R. L. Liesner & B. Holst 21248*; 19 Feb. 1987; Venezuela, T.F. Amazonas, Dept. Atures, stream 0.5–2 km E of Río Coro-Coro, W of Serranía de Yutaje; 200 m; MO (holo—3483070), NY, VEN.

Pochota robynsii Steyerm. & Stevens, Ann. Missouri Bot. Gard. 75: 1586, nom. nov.

Pochota tepuiensis Steyerm., Ann. Missouri Bot. Gard. 75: 1081. 1988. *J. A. Steyermark et al. 108938*; 11–12 Feb. 1974; Venezuela, Bolívar, Meseta de Jaua, Cerro Sarisariñama, summit; VEN (holo).

Scleronema neblinense Steyerm., Ann. Missouri Bot. Gard. 74: 645. 1987. *B. Maguire et al. 60181*; 15 Nov. 1986; Brazil, Amazonas, Serra de Neblina, vicinity Base Camp, Caño Tucano, Rio Cauaburi; 100 m; MO (holo), NY.

BONNETIACEAE = Theaceae

BORAGINACEAE

Lithospermum canescens (Michx.) Lehm. f. *pallidum* Palmer & Steyerm., Rhodora 57: 316. 1955. *J. A. Steyermark 73223*; 30 Apr. 1952; U.S.A., Missouri, Pike Co., Hwy. 54, 0.5 mi. SW of jct. with Hwy. 154, 4 mi. WSW of Curryville; F (holo), MO.

Mertensia virginica (L.) Pers. f. *rosea* Steyerm., Rhodora 62: 131. 1960. *J. A. Steyermark 67235*; 17 Apr. 1949; U.S.A., Missouri, Cass Co., N side of Big Creek, 4 mi. SE of Pleasant Hill; F (holo).

BRASSICACEAE

Cardamine balnearia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 157. 1944. *P. C. Standley 83332*; 14 Jan. 1941; Guatemala, Dept. Quezaltenango, Aguas Amargas, Volcán Zunil; 2,450 m; F (holo).

Cardamine bulbosa (Schreb.) Britt., Sterns & Pogg. f. *fontinalis* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 771. 1938. *J. A. Steyermark 12414*; 2 Aug. 1936; U.S.A., Missouri, Shannon Co., Pulltight Spring, near Current River; MO (holo—1175572) = *C. bulbosa* (Schreb.) Britt., Sterns & Pogg var. *bulbosa*, 1981.

Cardamine eremita Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 53. 1944. *J. A. Steyermark 50143*; 6 Aug. 1942; Guatemala, Dept. Huehuetenango, between Tojquiá and Caxix bluff, summit of Sierra de los Cuchumatanes; 3,700 m; F (holo).

Cardamine jejuna Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 54. 1944. *J. A. Steyermark 50569*; 15 Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Pixpix, Sierra de los Cuchumatanes; 2,800 m; F (holo).

Brunellia zamorensis Steyerm., Phytologia 9(6): 344. 1964. *J. A. Steyermark 53576*; 13 July 1943; Ecuador, Prov. Santiago-Zamora, arenillas along Río Tintas, 10 leagues SE of El Pan; 2,195 m; F (holo).

BURMANNIACEAE

Burmannia carrenoi Steyerm., Acta Bot. Venez. 6: 89. 1971. *J. A. Steyermark et al. 104418*; 25 Dec. 1970; Venezuela, Bolívar, vicinity of K.134 S of El Dorado, Río Anawa-ray-paru; 1,350 m; NY, U, US, VEN (holo) = *B. kalbreyeri* Oliv., 1986.

Burmannia foliosa Gleason subsp. *marahuacensis* Maguire & Steyerm., Acta Bot. Venez. 14(3): 19. 1984. *J. A. Steyermark et al. 124383*; n.d.; Venezuela, T.F. Amazonas, Cerra Marahuaca; MO (2911054), NY (holo), VEN = *B. foliosa* Gleason subsp. *foliosa*, 1986.

Burmannia sanariapoana Steyerm., Fieldiana Bot. 28(1): 165. 1951. *J. A. Steyermark 58466*; 8 Sep. 1944; Venezuela, T.F. Amazonas, tributary of Orinoco, near Río Sanariapo, vicinity of Sanariapo; 100 m; F (holo), GH, NY, U, US.

BURSERACEAE

Bursera permollis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 166. 1944. *P. C. Standley 75245*; Oct.–Nov. 1940; Guatemala, Dept. Jutiapa, vicinity of Jutiapa; 850 m; F (holo).

Dacryodes chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 445. 1967. *J. A. Steyermark 75358*; 14 May 1953; Venezuela, Bolívar, Chimantá-tepui (Torono-tepui), Chimantá Massif; 1,000 m; NY (holo).

Dacryodes costanensis Steyerm., Acta Bot. Venez. 10: 235. 1975. *L. Aristeguieta 3036*; Apr. 1958; Venezuela, Miranda, Bosque de Los Guayabitos, arriba de Baruta; 1,350 m; VEN (holo).

Protium ptarianum Steyerm., Fieldiana Bot. 28(2): 275. 1952. *J. A. Steyermark 59994*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585-1,600 m; F (holo).

Protium ptarianum Steyerm. var. *angusitor* Steyerm., Fieldiana Bot. 28(2): 276. 1952. *J. A. Steyermark 59987*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Protium puberulenta Steyerm., Fieldiana Bot. 28(2): 276. 1952. *J. A. Steyermark 60460*; 23 Nov. 1944; Venezuela, Bolívar, 8 mi. NW of Kavanayen; 1,220 m; F (holo).

Trattinickia glabra Steyerm., Fieldiana Bot. 28(2): 277. 1952. *J. A. Steyermark 60312*; 18 Nov. 1944; Venezuela, Bolívar, between Santa Teresita de Kavanayen and base of Ptari-tepui; 1,220 m; F (holo).

CACTACEAE

Bonifazia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 66. 1944, gen. nov.

Bonifazia quezalteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 66. 1944. *P. C. Standley 85603*; 1 Feb. 1941; Guatemala, Dept. Quezaltenango, above Mujuliá, between San Martín Chile Verde and Colombia; 1,800 m; F (holo) = *Epiphyllum quezaltecum* (Steyerm.) L. Williams, 1961.

Heliocereus heterodoxus Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 67. 1944. *J. A. Steyermark 36291*; 21 Feb. 1940; Guatemala, Dept. San Marcos, along Río Vega between San Rafael and NE part of Volcán Tacaná; 2,500–3,000 m; F (holo) = *H. cinnabarinus* (Eichl.) Britt. & Rose, 1961.

CAMPANULACEAE

Lobelia laxiflora H.B.K. f. *lutea* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 98. 1944. *P. C. Standley 67195*; 1 Mar. 1939; Guatemala, Dept. Quezaltenango, above Santa María de Jesús; 1,650 m; F (holo) = *L. laxiflora* H.B.K. var. *laxiflora*, 1976.

Lobelia siphilitica L. f. *purpurea* Palmer & Steyerm., Brittonia 10: 118. 1958. *J. A. Steyermark 79674*; 19 Sep. 1955; U.S.A., Missouri, Adair Co., along Chariton River, 2.5 mi. S of Youngstown; F (holo).

Siphocampylus tillettii Steyerm., Brittonia 30: 50. 1978. *S. S. Tillett et al. 752–329*; 2 Feb. 1975; Venezuela, T.F. Amazonas, Cerro Marahuaca; 2,750 m; NY (holo).

CANELLACEAE

Cinnamodendron venezuelense Steyerm., Fieldiana Bot. 28(2): 402. 1952. *J. A. Steyermark 61950*; 9 Apr. 1945; Venezuela, Monagas, SW of Caripe, along Quebrada Colorado Grande; 850–1,350 m; F (holo).

CAPPARACEAE

Capparis calciphila Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 158. 1944. *J. A. Steyermark 45616*; 1–2 Apr. 1942; Guatemala, Dept. Alta Verapaz, Cerro Chinajá; 150–700 m; F (holo).

Capparis grandipetala Maguire & Steyerm., in press, Mem. New York Bot. Gard. *N. T. Silva & U. Brazao 60719*; 22 Dec. 1965; Brazil; NY (holo), MO (3291196).

Capparis guaguaensis Steyerm., Fieldiana Bot. 28(1): 238. 1951. *J. A. Steyermark 62800*; 18 May 1945; Venezuela, Sucre, above Cuchivano, along Río Guagua, tributary to Río Manzanares; 230–300 m; F (holo).

CAPRIFOLIACEAE

Sambucus canadensis L. f. *rubra* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 773, 1938. *E. J. Palmer 18928*; 3 Sep. 1920; U.S.A., Missouri, Atchison Co., Watson; GH (holo).

Viburnum brunnescens Standl. & Steyerm., Field Mus. Natl. Hist., Bot. Ser. 23(2): 89. 1944. *J. A. Steyermark 49855*; 31 July 1942; Guatemala, Dept. Huehuetenango, Cruz de Limón, Sierra de los Cuchumatanes; 2,600–3,000 m; F (holo) = *V. jucundum* Morton, 1976.

Viburnum detractum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 90. 1943. *J. A. Steyermark 34590*; 22 Jan. 1940; Guatemala, Dept. Quezaltenango, Volcán Zunil, above Fuentes Georginas; 3,000 m; F (holo) = *V. jucundum* Morton var. *detractum* (Standl. & Steyerm.) D. Gibson, 1973.

Viburnum euryphyllum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 90. 1944. *J. A. Steyermark 48425*; 8 July 1942; Guatemala, Dept. Huehuetenango, between Tunima and Quisil, Sierra de los Cuchumatanes; 2,500–3,100 m; F (holo).

Viburnum mortonianum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 294. 1940. *J. A. Steyermark 31606*; 10 Nov. 1939; Guatemala, Dept. Chiquimula, Cerro Tixixí; 1,500 m; F (holo).

Viburnum tinoides L.f. var. *roraimense* (Killip & Smith) Steyerm. f. *turumiquirense* Steyerm.; Field Mus. Nat. Hist., Bot. Ser. 28(3): 619. 1953. *J. A. Steyermark 62691*; 10 May 1945; Venezuela, Sucre, Cerro Turumiquire; 1,300–1,800 m; F (holo).

CARYOPHYLLACEAE

Arenaria altorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 49. 1944. *J. A. Steyermark 33091*; 12 Dec. 1939; Guatemala, Dept. Jalapa, near Minas de Croma, Potrero Carrillo; 1,500–1,700 m; F (holo).

Arenaria chiapensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 50. 1944. *Ghiesbreght 871*; 1864–1870; Mexico, Chiapas; F (holo).

Arenaria guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 50. 1944. *J. A. Steyermark 36268*; Feb. 1940; Guatemala, Dept. San Marcos, Río Vega, near San Rafael and Guatemala–Mexico border, Volcán Tacaná; 2,500–3,000 m; F (holo).

Arenaria patula Michx. f. *media* Steyerm., Rhodora 43: 331. 1941. *Gattinger s.n.*; May; U.S.A., Tennessee, rocky glades near Nashville; F (holo), G, M.

Arenaria patula Michx. f. *robusta* Steyerm., Rhodora 43: 330. 1941. *J. A. Steyermark 26652*; 27 May 1939; U.S.A., Missouri, Butler Co., along Gillis Bluff, section 8 and 17, 5 mi. SW of Giulin; F (holo), MO (1198045) = *Minuartia patula* var. *robusta* (Steyerm.) Maguire, 1988.

Cerastium juniperorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 51. 1944. *J. A. Steyermark 48413*; 7 July 1942; Guatemala, Dept. Huehuetenango, Tunima, Sierra de los Cuchumatanes; 3,400–3,500 m; F (holo).

Drymaria firmula Steyerm., Fieldiana Bot. 28(1): 227. 1951. *J. A. Steyermark 56536*; 14 May 1944; Venezuela, Mérida, between El Molino and San Isidro Alto, Páramo de Los Colorados; 2,745–2,955 m; F (holo).

Drymaria minuscula Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 52. 1944. *J. A. Steyermark 50243*; 8 Aug. 1942; Guatemala, Dept. Huehuetenango, Chemal, summit of Sierra de los Cuchumatanes; 3,700 m; F (holo).

Stellaria ovata Willd. f. *paradoxa* Steyerm., Fieldiana Bot. 28(1): 228. 1951. *J. A. Steyermark 55217*; 3 Feb. 1944; Venezuela, Lara, above Humocaro Bajo, above Las Sabanetas, Los Aposentos; 2,500–2,530 m; F (holo).

Stellaria venezuelana Steyerm., Fieldiana Bot. 28(1): 229. 1951. *J. A. Steyermark 62739*; 11 May 1945; Venezuela, Sucre, Cerro de Diablo base; 2,000–2,100 m; F (holo).

CECROPIACEAE

Cecropia sylvicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 153. 1944. *P. C. Standley 90762*; Apr. 1941; Guatemala, Dept. Alta Verapaz, between Tactic & divide on road to Tamahu; 1,500–1,600 m; F (holo).

CELASTRACEAE

Maytenus agostinii Steyerm., Ernstia 23: 34. 1984. *G. Agostini & M. Farinas 84*; 28 Oct. 1963; Venezuela, Aragua, Parque Nacional Henri Pittier; VEN (holo).

Maytenus apiculata Steyerm., Fieldiana Bot. 28(2): 334. 1952. *J. A. Steyermark 60385*; 20–21 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma; 1,065–1,220 m; F (holo).

Maytenus coriacea Steyerm., Fieldiana Bot. 28(2): 337. 1952. *J. A. Steyermark 56509*; 14 May 1944; Venezuela, Mérida, above El Molino; 2,010–2135 m; F (holo).

Maytenus guianensis Klotzsch f. *crenulata* Steyerm.; Fieldiana Bot. 28(2): 338. 1952. *J. A. Steyermark 61731*; 23 Mar. 1945; Venezuela, Anzoátegui, Fila Grande; 900–1,400 m; F (holo).

Maytenus huberi Steyerm., Ann. Missouri Bot. Gard. 75: 1062. 1988. *O. Huber 441*; 29 Jan. 1977; Venezuela, T.F. Amazonas, Dept. Atures, cuenca del Río Manapiare, en los cerros ubicados entre el Cerro Morrocoy al sur y Serranía Colmena al Norte; 200–300 m; VEN (holo).

Maytenus insculpta Steyerm., Ann. Missouri Bot. Gard. 75: 1063. 1988. *O. Huber 1229*; 16 Oct. 1977; Venezuela, T.F. Amazonas, Dept. Atures, cuenca del Río Manapiare, los cerros al N del Cerro Morrocoy, 12 km W of San Juan de Manapiare; 225 m; MO, VEN (holo).

Maytenus jauaensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 346. 1976. *J. A. Steyermark et al. 109252*; 19–

20 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Sarasariñama; 1,350 m; VEN (holo).

Maytenus longistipitata Steyerm., Ann. Missouri Bot. Gard. 75: 1064. 1988. *B. Maguire et al. 53731*; 12 Sep. 1962; Venezuela, Bolívar, Cerro Uroi, summit, N portion, Río Uroi, Río Chicanán; 700 m; MO, VEN (holo).

Maytenus neblinae Steyerm., Ann. Missouri Bot. Gard. 75: 1064. 1988. *T. Plowman & W. Thomas 13610*; 15 Apr. 1984; Venezuela, T.F. Amazonas, Cerro de la Neblina, 26 km ENE of Base Camp; 2,000 m; F, MO (holo), VEN.

Maytenus parvifolia Steyerm., Fieldiana Bot. 28(2): 338. 1952. *J. A. Steyermark 55832*; 30 Mar. 1944; Venezuela, Mérida, between Pinango and Las Corales; 3,333 m; F (holo).

Maytenus pittieriana Steyerm., Fieldiana Bot. 28(2): 338. 1952. *Ll. Williams 13650*; Dec. 1939; Venezuela, Distr. Federal, above La Guaira; 750 m; F (holo).

Maytenus pustulata Steyerm., Ann. Missouri Bot. Gard. 75: 1064. 1988. *R. L. Liesner 16720*; 5 Mar. 1984; Venezuela, T.F. Amazonas, Cerro de la Neblina, Camp IV, 15 km NNE of Pico Phelps; 780 m; MO (holo), VEN.

Microtropis ilicina Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 170. 1944. *J. A. Steyermark 43284*; 26 Jan. 1942; Guatemala, Dept. Zacapa, S Volcán Gemelos, Sierra de las Minas; 2,100–3,200 m; F (holo).

Zinowiewia aymardii Steyerm., Ann. Missouri Bot. Gard. 75: 1064. 1988. *G. Aymard 4631*; 21 Oct. 1986; Venezuela, Bolívar, Distr. Sifontes, 7 km NW of Caserio El Pilón, 58 km W of Sta. Elena de Uairén; 850 m; MO (holo), PORT.

CHRYSOBALANACEAE

Licania costaricensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 335. 1940. *A. Smith F1779*; 14 Mar. 1939; Costa Rica, Prov. Alajuela, Villa Quesada, Cantón de San Carlos; 825 m; F (holo).

CLETHRACEAE

Clethra bimatris Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 17. 1943. *H. Kuylen 151*; July 1927; Guatemala, Dept. Izabal, Entre Ríos; F (holo) = *C. macrophylla* Mart. & Gal., 1961.

Clethra johnstonii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 258. 1940. *J. R. Johnston 1255*; 20 May 1938; Guatemala, Dept. Guatemala, Volcán de Pacaya, above Las Calderas; F (holo).

Clethra licanioides Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 17. 1943. *J. A. Steyermark 33124*; 12 Dec. 1939; Guatemala, Dept. Jalapa, Potrero Carrillo, 13 mi. NE of Jalapa; 1,500–1,700 m; F (holo).

Clethra pachecoana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 259. 1940. *P. C. Standley 65123*; 11 Feb. 1939. Guatemala, Dept. Sacatepéquez, Volcán de Agua, above Santa María de Jesús; 2,250–3,000 m; F (holo).

Clethra rugosa Steyerm., Phytologia 9(6): 347. 1964. *M. Acosta Solis 5054*; 20 July 1943; Ecuador, Prov. Santiago-Zamora, Campansa, Cordillera Oriental; 2,850 m; F (holo).

Clethra skutchii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 260. 1940. *A. F. Skutch 1453*; 14 Oct. 1934; Guatemala, Dept. Quezaltenango, Palmar; 1,350 m; F (holo).

CLUSIACEAE

Caraipa ferruginea Steyerm., Fieldiana Bot. 28(2): 384. 1952. *Ll. Williams 14140*; 2 Feb. 1942; Venezuela, T.F. Amazonas, Yavita; 128 m; F (holo) = *C. punctulata* Ducke, 1978.

Caraipa longipedicellata Steyerm., Fieldiana Bot. 28(2): 385. 1952. *J. A. Steyermark 60708*; 28 Nov. 1944; Venezuela, Bolívar, between Ptari-tepui and Sororopan-tepui; 1,220 m; F (holo).

Chrysochlamys pauciflora Steyerm., Fieldiana Bot. 28(2): 386. 1952. *J. A. Steyermark 60566*; 25 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma; 915–1,065 m; F (holo).

Clusia cerroana Steyerm., Fieldiana Bot. 28(2): 386. 1952. *J. A. Steyermark 59702*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,700–1,800 m; F (holo).

Clusia hexacarpa Gleason var. *ptaritepuiana* Steyerm., Fieldiana Bot. 28(2): 387. 1952. *J. A. Steyermark 59866*; 4 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,800 m; F (holo).

Clusia imbricata Steyerm., Fieldiana Bot. 28(2): 387. 1952. *J. A. Steyermark 59699*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,700–1,800 m; F (holo).

Clusia lusoria Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 63. 1944. *J. A. Steyermark 30987*; 2 Nov. 1939; Guatemala, Dept. Chiquimula, Montaña Norte to El Jutal, Cerro Brujo SE of Concepción de las Minas; 1,700–2,000 m; F (holo).

Clusia pusilla Steyerm., Fieldiana Bot. 28(2): 390. 1952. *J. A. Steyermark 59396*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

Clusia reducta Steyerm., Fieldiana Bot. 28(2): 391. 1952. *Ll. Williams 14898*; 26 Mar. 1942; Venezuela, T.F. Amazonas, Río Guianía; 125 m; F (holo).

Clusia roraimana Steyerm., Fieldiana Bot. 28(2): 391. 1952. *J. A. Steyermark 58606*; 25 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 1,030–1,115 m; F (holo).

Clusia williamsii Steyerm., Fieldiana Bot. 28(2): 392. 1952. *Ll. Williams 14143*; 2 Feb. 1942; Venezuela, T.F. Amazonas, Yavita; 128 m; F (holo).

Havetia laurifolia H.B.K. var. *venezuelana* Steyerm., Fieldiana Bot. 28(2): 392. 1952. *J. A. Steyermark 56592*; 18 May 1944; Venezuela, Mérida, above Tabay; 2,285–2,745 m; F (holo).

Hypericum arbuscula Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 63. 1944. *J. R. Johnston 1812*; 11 Apr. 1941; Guatemala, Dept. Baja Verapaz, Patal; F (holo).

Hypericum calcicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 64. 1944. *J. A. Steyermark 50160*; 6 Aug. 1942; Guatemala, Dept. Huehuetenango, Sierra de los Cuchumatanes; 3,700 m; F (holo).

Hypericum caracasanum Willd. var. *turumiquirense* Steyerm., Fieldiana Bot. 28(2): 393. 1952. *J. A. Steyermark 62579*; 6 May 1945; Venezuela, Sucre, Cerro Turumiquire; 2,360–2,500 m; F (holo).

Hypericum ericifolium Steyerm., Fieldiana Bot. 28(2): 393. 1952. *J. A. Steyermark 57212*; 14 July 1944; Venezuela, Táchira, Paramito; 2,500 m; F (holo).

Hypericum meridense Steyerm., Fieldiana Bot. 28(2): 394. 1952. *J. A. Steyermark 56272*; 3 May 1944; Venezuela, Mérida, Páramo de Pozo Negro; 2,590–3,220 m; F (holo).

Hypericum pseudocaracasanum Steyerm., Fieldiana Bot. 28(2): 394. 1952. *J. A. Steyermark 55346*; 6 Feb. 1944; Venezuela, Trujillo, La Quebrada Cortijo; 2,600–2,800 m; F (holo).

Hypericum pseudomaculatum Mack. & Bush f. *flavidum* Steyerm., Rhodora 41: 585. 1939. *J. A. Steyermark 56061*; 31 May 1938; U.S.A., Missouri, McDonald Co., along Mill Creek, 5 mi. SE of Pineville; F (holo), MO.

Mahurea sororopantepuiana Steyerm., Fieldiana Bot. 28(2): 395. 1952. *J. A. Steyermark 60129*; 14 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,255 m; F (holo).

Moronobea ptaritepuiana Steyerm., Fieldiana Bot. 28(2): 395. 1952. *J. A. Steyermark 59985*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Moronobea ptaritepuiana Steyerm. f. *rosea* Steyerm., Fieldiana Bot. 28(2): 397. 1952. *J. A. Steyermark 60892*; 7 Dec. 1944; Venezuela, Bolívar, Carrao-tepui; 2,470–2,500 m; F (holo).

Oedematopus ptaritepuiensis Steyerm., Fieldiana Bot. 28(2): 398. 1952. *J. A. Steyermark 59719*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,700–1,800 m; F (holo).

Rheedia macrantha Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 65. 1944. *P. C. Standley 90524*; 1 Apr. 1941; Guatemala, Dept. Alta Verapaz, Río Frio, ca. 8 km below Tactic; 1,400 m; F (holo).

Tovomita angustata Steyerm., Fieldiana Bot. 28(2): 399. 1952. *J. A. Steyermark 60475*; 23 Nov. 1944; Venezuela, ca. 8 km NW of Kavanayen; 1,220 m; F (holo).

Tovomita atropurpurea Steyerm., Fieldiana Bot. 28(2): 399. 1952. *J. A. Steyermark 59973*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Tovomita duidae Steyerm., Fieldiana Bot. 28(2): 400. 1952. *J. A. Steyermark 57975*; 25–26 Aug. 1944; Venezuela, T.F. Amazonas, Caño Negro, Cerro Duida; 305–1,095 m; F (holo).

COMBRETACEAE

Buchenavia ptariensis Steyerm., Fieldiana Bot. 28(2): 423. 1952. *J. A. Steyermark 60271*; 15–17 Nov. 1944; Venezuela, Bolívar, between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo).

COMMELINACEAE

Aneilema ecuadoriensis Steyerm., Phytologia 9(6): 339. 1964. *J. A. Steyermark 52813*; 3 June 1943; Ecuador, Prov. Azuay, between Chacanceo and Río Blanco, on road to Molleturo; 1,220 m; F (holo).

Campelia standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 32. 1944. *J. A. Steyermark 37187*; Mar. 1940; Guatemala, Dept. San Marcos, above Finca El Porvenir, on Todos Santos Chiquitos, Volcán Tajumulco; 1,300–1,500 m; F (holo).

Commelina alpestris Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 213. 1947. *J. A. Steyermark 50265*; 8 Aug. 1942; Guatemala, Dept. Huehuetenango, Sierra de los Cuchumatanes, vicinity of Chemal; 3,700 m; F (holo).

Commelina erecta L. var. *angustifolia* (Michx.) Fern. f. *cana* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 32. 1944. *J. A. Steyermark 29136*; 5 Oct. 1939; Guatemala, Dept. Zacapa, along RR between La Fragua and Estanzuela; 200 m; F (holo).

Commelina erecta L. f. *candida* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 33. 1944. *J. A. Steyermark 29267*; 7 Oct. 1939; Guatemala, Dept. Zacapa, between Zacapa and Santa Marta; 200 m; F (holo).

Commelina standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 33. 1944. *J. A. Steyermark 29644*; Oct. 1939; Guatemala, Dept. Zacapa, Sierra de las Minas, Finca Alejandría; 1,000–1,500 m; F (holo).

Dichorisandra diederichsanae Steyerm., Acta Bot. Venez. 8: 111. 1973. *J. A. Steyermark 106178*; 17–19 June 1972; Venezuela, Yaracuy, El Amparo hacia Candelaria; 1,220–1,250 m; VEN (holo).

Tinantia erecta (Jacq.) Schecht. f. *puberula* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 34. 1944. *H. S. Gentry 2525*; Aug. 1936; Mexico, Chihuahua, Sierra Canelo, Río Mayo; F (holo).

Tinanatia leiocalyx C. B. Clarke f. *glabra* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 34. 1944. *C. A. Purpus 16201*; Sep. 1934; Mexico, Veracruz, El Fortín; F (holo).

Tinantia longipedunculata Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 35. 1944. *Heyde & Lux 6392*; Jan. 1894; Guatemala, Dept. Escuintla, Santa Lucia; 300 m; F (holo).

Tinantia standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 35. 1944. *J. A. Steyermark 33605*; Jan. 1940; Guatemala, Dept. Quezaltenango, Volcán Santa María, between Santa María de Jesús and Calahuache; 1,300–1,500 m; F (holo).

Tradescantia aguensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 36. 1944. *P. C. Standley 59358*; Dec. 1938; Guatemala, Dept. Sacatepéquez, Volcán de Agua, N of Santa María de Jesús; 1,800–2,100 m; F (holo) = *Aneilema aguensis* (Standl. & Steyerm.) Standl. & Steyerm., 1944.

Tradescantia disgrega Kunth f. *glandulosa* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 36. 1944. *J. A. Steyermark 29751*; Oct. 1939; Guatemala, Dept. Zacapa, Sierra de las Minas, between Río Hondo and summit of mountain at Finca Alejandría; 1,000–1,500 m; F (holo) = *Tripogandra disgrega* Kunth f. *glandulosa* (Standl. & Steyerm.) Standl. & Steyerm., 1952.

Tradescantia disgrega Kunth f. *pubescens* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 37. 1944. *J. Morales R. 1106*; Oct. 1929; Guatemala, Dept. Guatemala; F (holo) = *Tripogandra disgrega* Kunth f. *pubescens* (Standl. & Steyerm.) Standl. & Steyerm., 1952.

Tradescantia guatemalensis C. B. Clarke f. *alba* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 37. 1944. *P. C. Standley 58025*; Nov. 1938–Feb. 1939; Guatemala, Dept. Sacatepéquez, near Antigua; 1,500–1,600 m; F (holo).

Tradescantia standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 36. 1944. *J. A. Steyermark 31696*; Nov. 1939; Guatemala, Dept. Chiquimula, summit of Montaña Nonojá, E of Camotán; 1,800 m; F (holo).

Tradescantia venezuelensis Steyerm., Fieldiana Bot. 28(1): 152. 1951. *J. A. Steyermark 62688*; 10 May 1945; Venezuela, Sucre, Cerro Turumiquire; 1,300–1,800 m; F (holo).

Zebrina huehueteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 213. 1947. *J. A. Steyermark*

51016; 22 Aug. 1942; Guatemala, Dept. Huehuetenango, along Río Trapichillo; 1,000–2,100 m; F (holo).

CONNARACEAE

Pseudoconnarus krukovii Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 141. 1940. *B. A. Krukoff 6455*; 14 Sep.–11 Oct. 1934; Brazil, Amazonas, Mun. Humayta, near Tres Casas; A, BM, BR, F (holo), G, K, MO, NY, U, US = *P. macrophyllus* (Poepp. & Endl.) Radl., 1983.

Rourea krukovii Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 142. 1940. *B. A. Krukoff 8556*; 11 Sep.–26 Oct. 1936; Brazil, Amazonas, Mun. São Paulo de Olivenca, near Palmares; A, BM, BR, F, G, K, MO, NY (holo), S, U.

CONVOLVULACEAE

Dicranostyles costanensis Steyerm. & Austin, Ann. Missouri Bot. Gard. 57: 155–157. 1970. *J. A. Steyermark et al. 100263*; n.d.; Venezuela, Yaracuy, Cerro La Chapa; 1,200–1,400 m; VEN (holo).

Dicranostyles imatacensis Steyerm., Acta Bot. Venez, 3: 190. 1968. *J. A. Steyermark 87129*; 31 Oct. 1960; Venezuela, Terr. Delta Amacuro, San Victor, Río Amacuro, Sierra Imataca; 65–80 m; NY (holo) = *D. guianensis* A. Mennega, 1982.

Ipomoea heterodoxa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 82. 1944. *P. Gentle 871*; Dec. 1933; Belize, Maskall; F (holo).

Ipomoea ophioides Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 82. 1944. *P. C. Standley 7884*; Dec. 1940; Guatemala, Dept. Santa Rosa, region of La Morenita, NE of Chiquimulilla; 400 m; F (holo).

Ipomoea santae-rosae Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 81. 1944. *P. C. Standley 79287*; Nov.–Dec. 1940; Guatemala, Dept. Santa Rosa, near Chiquimulilla; 325 m; F (holo).

Ipomoea saxorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 81. 1944. *J. A. Steyermark 30254*; 22 Oct. 1939; Guatemala, Dept. Chiquimula, gorge of Río Chiquimula, between Santa Barbara and Petapilla; 350–420 m; F (holo).

Itzaea Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 83. 1944, gen. nov.

Jacquemontia guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 84. 1944. *J. A. Steyermark 30066*; Oct. 1939; Guatemala, Dept. Chiquimula, Chiquimula; 400 m; F (holo) = *J. agrestis* (Choisy) Meisn., 1982.

Jacquemontia pinetorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 372. 1940. *J. A. Steyermark 38533*; 1 Apr. 1940; Guatemala, Dept. Izabal, Montaña del Mico; 65–6,000 m; F (holo).

Maripa stellulata Steyerm., Acta Bot. Venez. 3: 209. 1968. *J. A. & C. Steyermark 95456*; 2 Apr. 1966; Venezuela, Carabobo, Río San Gian, Planta Electrica; 350–550 m; MO, NY, U, US, VEN (holo).

CRASSULACEAE

Echeveria bicolor (H.B.K.) E. Walther var. *turumiquirensis* Steyerm., Fieldiana Bot. 28(2): 244. 1952. *J. A. Steyermark 62491*; 5 May 1945; Venezuela, Sucre, Cerro Turumiquire; 1,700–2,000 m; F (holo).

Echeveria huehueteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 159. 1944. *J. A. Steyermark 50934*; 19 Aug. 1942; Guatemala, Dept. Huehuetenango; Cumbre Papal; 1,400–3,000 m; F (holo).

Echeveria macrantha Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 159. 1944. *J. A. Steyermark 32808*; 6 Dec. 1939; Guatemala, Dept. Jalapa, Montaña Miramundo at Buena Vista; 2,000–2,200 m; F (holo).

Tillaea venezuelensis Steyerm., Fieldiana Bot. 28(4): 914. 1957. *J. A. Steyermark 55906*; 15 Apr. 1944; Venezuela, Mérida, between Chachopo and Los Apartaderos, near El Aquila; 3,030 m; F (holo).

CRUCIFERAE see Brassicaceae

CUCURBITACEAE

Ahzolia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 92. 1944, gen. nov.

Anguria simplicifolia Steyerm., Fieldiana Bot. 28(3): 620. 1953. *J. A. Steyermark 60161*; 15 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,130–2,250 m; F (holo).

Corallocarpus guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 93. 1944. *P. C. Standley 74623*; Oct. 1940; Guatemala, Dept. Zacapa, Zacapa; 200 m; F (holo) = *Doyerea emetocathartica* Grosourdy, 1976.

Elaterium macrophyllum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 94. 1944. *H. von Tuerckheim II.1728*; Apr. 1907; Guatemala, Dept. Baja Verapaz, above Pansal; 1,400 m; F (holo) = *Rytidostylis macrophyllus* (Standl. & Steyerm.) Dieterle, 1976.

Rytidostylis brevisetosa Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 148. 1965. *J. A. Steyermark 91499*; 7 June 1963; Venezuela, Distr. Federal, between Hacienda El Limón and Junquito-Colonia Tovar road; 1,750 m; VEN (holo).

Sicydium araguense Steyerm. & Trujillo, Bol. Soc. Venez. Ci. Nat. 25: 245. 1964. *J. A. Steyermark 89813*; 20 Oct. 1961; Venezuela, Aragua, Parque Nacional Henri Pittier; 1,500–1,700 m; US, VEN (holo).

Sicydium glabrum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 95. 1944. *J. A. Steyermark 34273*; 17 Jan. 1940; Guatemala, Dept. Quezaltenango, Montaña Chícharro, Volcán Santa María; 1,400–1,500 m; F (holo).

Sicyos guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 96. 1944. *J. A. Steyermark 32140*; 28 Nov. 1939; Guatemala, Dept. Jalapa, vicinity of Jalapa; 1,300 m; F (holo).

Tecunumania Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 96. 1944, gen. nov.

Tecunumania quetzalteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 97. 1944. *P. C. Standley 68931*; 15 Mar. 1939; Guatemala, Dept. San Marcos, Finca Vergel, near Rodeo; 900 m; F (holo).

CUNONIACEAE

Weinmannia neblinensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 42226*; 25 Nov. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina, Caño Grande; 1,200–2,200 m; MO (3291190), NY (holo).

CUPRESSACEAE

Juniperus standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 3. 1944. *J. A. Steyermark 36137*; Feb.

1940; Guatemala, Dept. San Marcos, Volcán Tacaná; 4,100–4,400 m; F (holo).

CYPERACEAE

Bulbostylis svensoniana Steyerm., Fieldiana Bot. 28(1): 37. 1951. *J. A. Steyermark 57629*; 2 Aug. 1944; Venezuela, Bolívar, between Upata and Río Caroni; 400 m; F (holo).

Carex azuayae Steyerm., Phytologia 9(6): 337. 1964. *J. A. Steyermark 53105*; 15 June 1943; Ecuador, Prov. Azuay, near Toreador; 3,785–3,900 m; F (holo).

Carex culmenicola Steyerm., Fieldiana Bot. 28(1): 65. 1951. *J. A. Steyermark 62605*; 6 May 1944; Venezuela, Sucre, Cerro Turumiquire; 2,500 m; F (holo).

Carex huehueteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 195. 1947. *J. A. Steyermark 49055*; 18 July 1942; Guatemala, Dept. Huehuetenango, Cananá, Sierra de los Cuchumatanes; 2,500 m; F (holo).

Carex larensis Steyerm., Fieldiana Bot. 28(1): 66. 1951. *J. A. Steyermark 55470*; 11 Feb. 1944; Venezuela, Lara, between Buenos Aires and Páramo de las Rosas; 2,285–3,290 m; F (holo).

Carex roraimensis Steyerm., Fieldiana Bot. 28(1): 67. 1951. *J. A. Steyermark 58870*; 28 Sep. 1944; Venezuela, Bolívar, Mt. Roraima, Summit Camp, Great Central Rift, Central Swamp; 2,700–2,740 m; F (holo).

Carex standleyana Steyerm., Ceiba 3: 23. 1952. *L. O. Williams 13178*; 6 July 1947; Guatemala, Dept. Jalapa, mountains above Aguacate; 2,150 m; F (holo).

Carex tachirensis Steyerm., Fieldiana Bot. 28(1): 68. 1951. *J. A. Steyermark 57367*; 15 July 1944; Venezuela, near Colombia–Venezuela border, Tachira, Páramo de Tamá; 3,045–3,475 m; F (holo).

Carex tamana Steyerm., Fieldiana Bot. 28(1): 70. 1951. *J. A. Steyermark 57401*; 15 July 1944; Venezuela, near Colombia–Venezuela border, Táchira, Páramo de Tamá; 3,045–3,475 m; F (holo).

Carex tojquianensis Standl. & Steyerm, Ceiba 4: 64. 1953. *J. A. Steyermark 50150*; 6 Aug. 1942; Guatemala, Dept. Huehuetenango, summit Sierra de los Cuchumatanes, between Tojquia and Caxix bluff; 3,700 m; F (holo).

Carex toreadora Steyerm., Phytologia 9(6): 338. 1964. *J. A. Steyermark 53095*; 15 July 1943; Ecuador, Prov. Azuay, near Toreador; 3,785–3,900 m; F (holo).

Carex tunimanenisis Standl. & Steyerm., Ceiba 4: 65. 1953. *J. A. Steyermark 48334*; 7 July 1942; Guatemala, Dept. Huehuetenango, near Tunima, Sierra de los Cuchumatanes; 3,400–3,500 m; F (holo).

Carex turumiquirensis Steyerm., Fieldiana Bot. 28(1): 70. 1951. *J. A. Steyermark 62705*; 10 May 1945; Venezuela, Sucre, Cerro Turumiquire, headwaters of Río Manzanares and Río de Amana; 1,900–2,000 m; F (holo).

Carex venosivaginata Standl. & Steyerm., Ceiba 4: 67–68. 1953. *J. A. Steyermark 48554*; 14 July 1942; Guatemala, Dept. Huehuetenango, Cerro Huitz, Sierra de los Cuchumatanes; 2,600 m; F (holo).

Cladium costatum Steyerm., Fieldiana Bot. 28(1): 50. 1951. *J. A. Steyermark 60829*; 3 Dec. 1944; Venezuela, Bolívar, Quebrada Sororopan between Santa Teresita de Kavanayen and Río Tek-Yunsen; 1,375 m; F (holo).

Fimbristylis tamaensis Steyerm., Fieldiana Bot. 28(1): 39. 1951. *J. A. Steyermark 57422*; 17 July 1944; Colombia–Venezuela border, along Río Táchira, between Delicias and Paraquita; 1,675–1,980 m; F (holo).

Hypolytrum tepuianum Steyerm., Fieldiana Bot. 28(1): 51. 1951. *J. A. Steyermark 60238*; 15–17 Nov. 1944; Venezuela, Bolívar, vicinity 'Misia Kathy Camp' on mesa between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo) = *Mapania tepuiana* (Steyerm.) T. Koyama, 1967.

Mapania maguireana T. Koyama & Steyerm., Mem. New York Bot. Gard. 17(1): 63. 1967. *B. Maguire & D. B. Fanshawe 32351*; Guyana, Membaru–Kurupung trail, Kakaralli forest; 1,000 m; NY (holo).

Oreobolus venezuelensis Steyerm., Bol. Soc. Venez. Ci. Nat. 11: 308. 1950. *J. A. Steyermark 57198*; 14 July 1944; Venezuela, Táchira, paramito at base of Páramo de Tamá; 2,500 m; F (holo).

Rhynchospora bolivarana Steyerm., Fieldiana Bot. 28(1): 40. 1951. *J. A. Steyermark 60206*; 15 Nov. 1944; Venezuela, Bolívar, Salto de Iwaracuru-meru, W end Sororopan-tepui; 1,500 m; F (holo).

Rhynchospora culmenicola Steyerm., Fieldiana Bot. 28(1): 41. 1951. *J. A. Steyermark 62110*; 15 Apr. 1945; Venezuela, Monagas, Cerro Negro; 2,180 m; F (holo) = *R. dissitiflora* Steudel, 1972.

Rhynchospora duidae Steyerm., Fieldiana Bot. 28(1): 43. 1951. *J. A. Steyermark 68254*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,065–1,220 m; F (holo).

Rhynchospora karuaiana Steyerm., Fieldiana Bot. 28(1): 43. 1951. *J. A. Steyermark 60334*; 18 Nov. 1944; Venezuela, Bolívar, Río Karuai, between Teresita de Kavanayen and base of Ptari-tepui; 1,200 m; F (holo) = *R. triflora* (Poir.) Vah., 1972.

Rhynchospora paramora Steyerm., Fieldiana Bot. 28(1): 44. 1951. *J. A. Steyermark 56550*; 14 May 1944; Venezuela, Mérida, Páramo de los Colorados, between El Molino and San Isidro Alto; 2,745–2,955 m; F (holo).

Rhynchospora ptaritepuiana Steyerm., Fieldiana Bot. 28(1): 45. 1951. *J. A. Steyermark 59830*; 4 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,130 m; F (holo) = *R. lechleri* Steudel, 1972.

Rhynchospora sanariapensis Steyerm., Fieldiana Bot. 28(1): 46. 1951. *J. A. Steyermark 58469*; 8 Sep. 1944; Venezuela, T.F. Amazonas, tributary of Orinoco River, near Río Sanariapo, vicinity of Sanariapo; F (holo).

Rhynchospora sororopana Steyerm., Fieldiana Bot. 28(1): 46. 1951. *J. A. Steyermark 60831*; 3 Dec. 1944; Venezuela, Bolívar, between Santa Terresita de Kavanayen and Río Tek-Yunsen, along Quebrada Sororopan; F (holo) = *R. biflora* Bockeler, 1972.

Rhynchospora tamana Steyerm., Fieldiana Bot. 28(1): 47. 1951. *J. A. Steyermark 57404*; 15 July 1944; Venezuela, Táchira, Páramo de Tamá, along border; 3,045–3,475 m; F (holo).

Rhynchospora tepuiana Steyerm., Fieldiana Bot. 28(1): 48. 1951. *J. A. Steyermark 58652*; 25 Sep. 1944; Venezuela, Bolívar, Mt. Roraima, near Rondon Camp; 2,040 m; F (holo) = *R. flexuosa* C. B. Clarke subsp. *tepuiana* Steyerm., 1972.

Rhynchospora tomentosa Steyerm., Fieldiana Bot. 28(1): 49. 1951. *J. A. Steyermark 57391*; 15 July 1944; Venezuela, Táchira, Páramo de Tamá, on border; 3,045–3,475 m; F (holo).

Rhynchospora trichochaeta C. B. Clarke var. *venezuelensis* Steyerm., Fieldiana Bot. 28(1): 49. 1951. *J. A.*

Steyermark 57587; 1 Aug. 1944; Venezuela, Bolívar, between Ciudad Bolívar and Río Caroni; 100 m; F (holo) = *R. subplumosa* C. B. Clarke, 1972.

Uncinia meridensis Steyerm., Fieldiana Bot. 28(1): 61. 1951. *J. A. Steyermark 57039*; 6 July 1944; Venezuela, Mérida, El Aquila above Páramo de Mucuchies; 4,025 m; F (holo).

Vesicarex Steyerm., Fieldiana Bot. 28(1): 63. 1951 gen. nov.

Vesicarex collumanthus Steyerm., Fieldiana Bot. 28(1): 63. 1951. *J. A. Steyermark 57040*; 6 July 1944; Venezuela, Mérida, El Aquila, above Páramo de Mucuchies; 4,025 m; F (holo).

DICHAPETALACEAE

Dichapetalum bullatum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 169. 1944. *J. A. Steyermark 39874*; 7 Dec. 1941; Guatemala, Dept. Izabal, along road between Puerto Barrios and Santo Tomás; sea level; F (holo).

DILLENIACEAE

Doliocarpus esmeraldae Steyerm., Fieldiana Bot. 28(2): 366. 1952. *J. A. Steyermark 57879*; 23 Aug. 1944; Venezuela, T.F. Amazonas, between Sabana Grande and SE base of Cerro Duida; 200 m; F (holo).

Doliocarpus ptariensis Steyerm., Fieldiana Bot. 28(2): 367. 1952. *J. A. Steyermark 59972*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

DIOSCOREACEAE

Dioscorea abysmophila Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 42319*; 8–9 Dec. 1957; Venezuela; MO (3291186), NY (holo).

Dioscorea bolivarensis Steyerm., Fieldiana Bot. 28(1): 158. 1951. *J. A. Steyermark 57551*; 31 July 1944; Venezuela, Bolívar, W of Upata, Río Upata; 500 m; F (holo).

Dioscorea lasseriana Steyerm., Fieldiana Bot. 28(1): 158. 1951. *J. A. Steyermark 61836*; 5 Apr. 1949; Venezuela, Monagas, between La Sabana de las Piedras and Cerro Negro, NW of Caripe; 1,200-1,500 m; F (holo).

Dioscorea neblinensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 37328*; 16 Jan. 1954; Venezuela; MO (3291183), NY (holo).

Dioscorea sororopana Steyerm., Fieldiana Bot. 28(1): 159. 1951. *J. A. Steyermark 60124*; 14 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,255 m; F (holo).

DIPSACACEAE

Dipsacus sylvestris Huds. f. *albidus* Steyerm., Rhodora 60: 174–175. 1959. *K. E. Bartel 1*; 25 Aug. 1957; U.S.A., Illinois, Cook Co., Chicago, Mt. Hope Cemetery on 115th St.; F (holo).

DIPTEROCARPACEAE

Pakaraimaea dipterocarpacea Maguire & Ashton subsp. *nitida* Maguire & Steyerm., Mem. New York Bot. Gard. 32: 308. 1981. *J. A. Steyermark et al. 113438*; 20–25 Jan. 1977; Venezuela, Bolívar, Cerro Guaiquinima; 750 m; NY (holo). VEN.

DROSERACEAE

Drosera arenicola Steyerm., Fieldiana Bot. 28(2): 243. 1952. *J. A. Steyermark 60920*; 16–17 Sep. 1944; Venezuela, Bolívar, vicinity of Santa Teresita de Kavanayen; 1,220 m; F (holo).

Drosera felix Steyerm. & L. B. Smith, Rhodora 76: 491. 1974. *J. A. Steyermark et al. 105468*; 19 Feb. 1972; Venezuela, Bolívar, carretera El Dorado to Santa Elena de Uairen, S of El Dorado; 1,200–1,400 m; MO (2670118), NY, US, VEN (holo).

Drosera sanariapoana Steyerm., Fieldiana Bot. 28(2): 243. 1952. *J. A. Steyermark 58472*; 8 Sep. 1944; Venezuela, T.F. Amazonas, vicinity of Sanariapo; 100 m; F (holo).

Drosera tenella Willd. var. *esmeraldae* Steyerm., Fieldiana Bot. 28(2): 244. 1952. *J. A. Steyermark 57850*; 22 Aug. 1944; Venezuela, T.F. Amazonas, between Esmeralda savanna and SE base of Cerro Duida; 200 m; F (holo) = *D. esmeraldae* (Steyerm.) Maguire & Wurd., 1957.

EBENACEAE

Diospyros anzoateguiensis Steyerm., Fieldiana Bot. 28(3): 489. 1953. *J. A. Steyermark 61513*; 16 Mar. 1945; Venezuela, Anzoátegui, between Bergantín and San José; 300–400 m; F (holo).

Diospyros johnstoniana Standl. & Steyerm., Fieldiana Bot. 22(3): 165. 1940. *P. C. Standley 59934*; Guatemala, Dept. Sacatepéquez, along Río Guacalate, near Pastores; 1,600 m; F (holo).

Diospyros virginiana L. f. *pumila* Palmer & Steyerm., Ann. Missouri Bot. Gard 22: 616. 1935. *B. F. Bush 7041*; 6 June 1913; U.S.A., Missouri, Dodson; GH (holo) = *D. virginiana* L. var. *pubescens* (Pursh) Dippel f. *pumila* (Palmer & Steyerm.) Steyerm., 1960.

Diosypros zacapana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 263. 1940. *J. A. Steyermark 29490*; 10 Oct. 1939; Guatemala, Dept. Zacapa, Sierra de las Minas; 250–400 m; F (holo) = *D. yatesiana* Standl., 1967.

ELAEOCARPACEAE

Sloanea autanae Steyerm., Pittieria 7: 13. 1978. *J. A. Steyermark 105222*; 21–22 Sep. 1971; Venezuela, T.F. Amazonas, Cerro Autana; 1,230–1,270 m; VEN (holo) = *S. steyermarkii* C. E. Smith subsp. *autanae* (Steyerm.) Steyerm., 1988.

Sloanea bolivarensis Steyerm.; Ann. Missouri Bot. Gard. 75: 1572. 1988. *R. L. Liesner & A. González 11479*; 10 Apr. 1981; Venezuela, Bolívar, 7 km NE of Ciudad Píar; 350–500 m; VEN (holo), MO.

Sloanea breviseta Steyerm., Fieldiana Bot. 28(2): 357. 1952. *J. A. Steyermark 62215*; 19 Apr. 1945; Venezuela, Monagas, Montaña de Aguacate; 600–900 m; F (holo).

Sloanea carrenoi Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 349. 1976. *J. A. Steyermark et al. 109699*; 28 Feb.–1,2,5 Mar. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; VEN (holo).

Sloanea cataniapensis Steyerm., Ann. Missouri Bot. Gard. 75: 1572. 1988. *J. A. Steyermark et al. 122215*; Venezuela, T.F. Amazonas, Dept. Atures, N side of Río Cataniapo, 48 km SE of Puerto Ayacucho; 200–300 m; MO, VEN (holo).

Sloanea caudata Steyerm., Fieldiana Bot. 28(2): 357. 1952. *J. A. Steyermark 60544*; 25 Nov. 1944; Ven-

ezuela, Bolívar, Quebrada O-paru-ma; 915–1,065 m; F (holo).

Sloanea cavicola Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 351. 1976. *J. A. Steyermark et al. 109039*; 13 Feb. 1974;. Venezuela, Bolívar, Meseta del Jaua, Cerro Sarasariñama; 1,320 m; MO (2582381), VEN (holo).

Sloanea davidsei Steyerm., Ann. Missouri Bot. Gard. 75: 1575. 1988. *G. Davidse 27733*; 23–25 July 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, Río Pacimoni, between its mouth and its jct. with the Río Baria and Río Yatua; 80 m; MO, VEN (holo).

Sloanea jauaensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 353. 1976. *J. A. Steyermark et al. 109841*; 28 Feb.–1,2,5 Mar. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,810–1,880 m; VEN (holo) = *S. steyermarkii* C. E. Smith subsp. *jauaensis* (Steyerm.) Steyerm., 1988.

Sloanea jauaensis Steyerm. var. *minor* Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 354, 1976. *J. A. Steyermark et al. 109695*; 28 Feb. 1976; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,810–1,880 m; VEN (holo) = *S. steyermarkii* C. E. Smith subsp. *jauaensis* (Steyerm.) Steyerm., 1988.

Sloanea larensis Steyerm., Acta Bot. Venez. 10: 239. 1975. *J. A. Steyermark et al. 110148*; 6 July 1974; Venezuela, Lara, Distrito Jiménez, Cubiro; 1,850–1,950 m; VEN (holo).

Sloanea longiaristata Steyerm., Ann. Missouri Bot. Gard. 75: 1577. 1988. *R. Liesner 18455*; 8–9 Mar. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca, 1–2 km N of Sima Camp; 1,100 m; MO, VEN (holo).

Sloanea maroana Steyerm., Pittieria 7: 14. 1978. *J. A. Steyermark & G. S. Bunting 102799*; Venezuela, T.F. Amazonas, 1 km al este de Maroa; VEN (holo) = *S. floribunda* Spruce ex Benth., 1988.

Sloanea megacarpa Steyerm. & Marcano Berti, Bol. Soc. Venez. Ci. Nat. 26: 467. 1966. *L. Marcano Berti 418*; 29 Nov.–18 Dec. 1964; Venezuela, T.F. Delta Amacuro; E of Río Grande, NE of El Palmar; VEN (holo).

Sloanea merevariensis Pittier ex Steyerm., Ann. Missouri Bot. Gard. 75: 1579. 1988. *F. Cardona 1051* (also numbered *1053, 1055*); n.d.; Venezuela, Bolívar, Alto Río Guaña (Merevari) near Brazil frontier; F (holo), US, VEN.

Sloanea onotillo Steyerm., Fieldiana Bot. 28(2): 358. 1952. *J. A. Steyermark 61016*; 20 Feb. 1945; Venezuela, Anzoátegui, along Río León by Quebrada Danta; 500 m; F (holo).

Sloanea onotillo Steyerm. var *major* Steyerm., Fieldiana Bot. 28(2): 359. 1952. *J. A. Steyermark 61726*; 23 Mar. 1945; Venezuela, Anzoátegui, Río Marville, Fila Grande; 900–1,400 m; F (holo).

Sloanea parvifructa Steyerm., Ann. Missouri Bot. Gard. 75: 1579. 1988. *N. T. Silva & U. Brazão 60865*; 23 Jan. 1966; Brazil (near Venezuelan border), Serra de Neblina, Río Negro, Río Cauaburí, Río Maturacá, between Missão Salesiana and Serra Pirapucú; 800–1,000 m; MO (holo), NY.

Sloanea petenensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 172. 1944. *J. A. Steyermark 45309*; 25 Mar. 1942; Guatemala, Dept. Petén, forest between Finca Yalpemech, along Río San Diego, and San Diego on Río Cancuén; 50–150 m; F (holo).

Sloanea pittieriana Steyerm., Fieldiana Bot. 28(2): 359. 1952. *J. A. Steyermark 60261*; 15–17 Nov. 1944; Venezuela, Bolívar, between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo).

Sloanea ptariana Steyerm., Fieldiana Bot. 28(2): 360. 1952. *J. A. Steyermark 60668*; 28 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo).

Sloanea sipapoana Steyerm., Ann. Missouri Bot. Gard. 75: 1580–1581. 1988. *B. Maguire & L. Politi 27674*; 15 Dec. 1948; Venezuela, T.F. Amazonas, Cerro Sipapo (Paráque), Camp Savanna; 1,500 m; MO (holo), NY.

Sloanea subpsilocarpa Steyerm., Ann. Missouri Bot. Gard. 75: 1583. 1988. *L. Marcano Berti 447*; 29 Nov.–18 Dec. 1964; Venezuela, T.F. Delta Amacuro, E de Río Grande, ENE El Palmar, near limits of Bolívar; VEN (holo), MO, NY.

Sloanea venezuelana Steyerm., Fieldiana Bot. 28(2): 361. 1952. *J. A. Steyermark 62216*; 19 Apr. 1945: Venezuela, Monagas, Montaña de Aguacate; 600–900 m; F (holo).

Sloanea wurdackii Steyerm., Ann. Missouri Bot. Gard. 75: 1583. 1988. *J. Wurdack & J. Monachino 41017*; 30 Dec. 1955; Venezuela, Bolívar, Río Paraguaza, just below Raudal Maraca (ca. 110 km above river mouth); 115 m; MO (holo), NY.

Sloanea yapacanae Steyerm., Pittieria 7: 15. 1978. *J. A. Steyermark & G. S. Bunting 103186*; Venezuela, T.F. Amazonas, Cerro Yapacana; 1,000–1,200 m; VEN (holo) = *S. steyermarkii* C. E. Smith subsp. *jauaensis* (Steyerm.) Steyerm., 1988.

ELATINACEAE

Elatine fassettiana Steyerm., Fieldiana Bot. 28(2): 400. 1952. *J. A. Steyermark 55905*; 16 Apr. 1944; Venezuela, Mérida, near El Aguila; 3,960 m; F (holo), MO (1621390).

ERICACEAE

Befaria neblinensis Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 141. 1978. *B. Maguire & J. Murca Pires 60477*; 2 Dec. 1965; Venezuela, T.F. Amazonas, Cerro de la Neblina; 2,500–2,800 m; NY (holo), VEN. Note: *Bejaria* is the correct spelling.

Cavendishia neblinae Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 165. 1978. *B. Maguire et al. 37254*; Venezuela, T.F. Amazonas, Cerro de la Neblina; 1,500–1,700 m; NY (holo), US.

Cavendishia salicifolia Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 167. 1978. *B. Maguire & D. B. Fanshawe 32430*; 29 Oct.–4 Nov. 1951; Guyana, Membaru–Kurupung trail; NY (holo), US.

Ceratostema glandulifera Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 160. 1978. *S. S. Tillett et al. 45057*; 8 Aug. 1960; Guyana, upper Mazaruni River, Mt. Ayanganna; 1,370–1,525 m; NY (holo).

Ledothamnus atroadenus Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 249. 1978. *J. A. Steyermark 73886*; 13 Apr. 1953; Venezuela, Bolívar, Chimantá Massif, Abacapa-tepui; 2,125–2,300 m; F, NY (holo), VEN.

Ledothamnus decumbens Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 143. 1978. *J. A. Steyermark & J. J. Wurdack 737*; 11 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,200 m; F, NY (holo), VEN.

Ledothamnus jauaensis Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 146. 1978. *J. A. Steyermark 97918*; 22–27 Mar. 1967; Venezuela, Bolívar, Meseta de Jaua, Cerro Sarasariñama; 2,000 m; NY (holo), VEN.

Ledothamnus luteus Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard 29(1): 146. 1978 *J. A. Steyermark & J. J. Wurdack 953*; 20 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 1,895–1,910 m; F, NY (holo), VEN.

Ledothamnus stenopetalus Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 149. 1978. *J. A. Steyermark 97944*; 22–27 Mar. 1967; Venezuela, Bolívar, Meseta de Jaua, Cerro Sarasariñama; 1,922–2,100 m; NY (holo), VEN.

Ledothamnus steyermarkii A. C. Smith subsp. *longisetus* Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 152. 1978. *J. A. Steyermark 97878*; 22–27 Mar. 1967; Venezuela, Bolívar, Meseta de Jaua, Cerro Sarasariñama; 1,922–2,100 m; NY (holo), VEN.

Mycerinus chimantensis Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 177. 1978. *J. A. Steyermark & J. J. Wurdack 825*; 13 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,210 m; F, NY (holo), VEN.

Mycerinus viridiflorus Steyerm. & Maguire, Bol. Soc. Ci. Nat. 32: 373. 1976. *J. A. Steyermark et al. 109181*; 16–18 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Sarisariñama; 1,400 m; VEN (holo).

Orthaea merumensis Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 168. 1978. *S. S. Tillett et al. 44867*; 12 July 1960; Guyana, Merume Mts., upper Mazaruni River basin; 520 m; NY (holo).

Orthaea paruensis Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 171. 1978. *R. S. Cowan & J. J. Wurdack 31061*; 31 Jan. 1951; Venezuela, T.F. Amazonas, Serranía Parú, Río Parú, Caño Asisa, along W Rim; 2,000 m; NY (holo).

Orthaea pubifolia Maguire, Steyerm. & Luteyn, Mem. New York Gard. 29(1): 171. 1978. *B. Maguire & D. Fanshawe 32339*; 29 Oct.–4 Nov. 1951; Guyana, Pakaraima Mts., Membaru–Kurupung trail; 1,000 m; NY (holo).

Orthaea thibaudioides Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 173. 1978. *B. Maguire et al. 30945*; 15 Jan. 1951; Venezuela, T.F. Amazonas, Cerro Moriche, Río Ventuari; 1,250 m; NY (holo).

Orthaea venamensis Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 174. 1978. *J. A. Steyermark et al. 92423*; 29–30 Dec. 1963; Venezuela, Bolívar, Cerro Venamo; 950–1,150 m; NY, VEN (holo).

Orthaea wurdackii Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 174. 1978. *B. Maguire et al. 42350*; 11 Dec. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina, Río Yatua; 1,900 m; NY (holo).

Pernettia saxicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 139. 1944. *J. A. Steyermark 36110*; 19 Feb. 1940; Guatemala, Dept. San Marcos, Volcán Tacaná; 4,400 m; F (holo).

Psammisia breweri Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 377. 1976. *J. A. Steyermark et al. 109076*; 12–15 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Sarasariñama; 1,000 m; VEN (holo) = *Psammisia urichiana* (Britt.) A. C. Smith, 1978.

Rhododendron roseum (Loisel.) Rehder f. *albidum* Steyerm., Rhodora 62: 131. 1960. *J. A. Steyermark 8522*; 24 May 1933; U.S.A., Missouri, Ste. Genevieve County, E of Chimney rocks, along River Aux Vases, 5 mi. E of Pickle; MO, UMO (holo).

Tepuia intermedia Steyerm., Acta Bot. Venez. 2: 303. 1967. *J. A. Steyermark 93980*; 15 May 1964; Venezuela, Bolívar, Auyan-tepui; 2,050–2,300 m; VEN (holo).

Tepuia multiglandulosa Steyerm. & Maguire, Acta Bot. Venez. 2: 301. 1967. *J. A. Steyermark 75733*; 19 June 1953; Venezuela, Bolívar, Auyan-tepui; 2,000 m; VEN (holo).

Tepuia tatei Camp var. *chimantana* Steyerm. & Maguire, Acta Bot. Venez. 2: 308. 1967. *J. A. Steyermark & J. J. Wurdack 387*; 4 Feb. 1955; Venezuela, Bolívar, Auyan-tepui; 1,925–1,940 m; VEN (holo).

Tepuia vareschii Steyerm., Acta Bot. Venez. 2: 306. 1967. *V. Vareschi & E. Foldats 4966*; Apr. 1956; Venezuela, Bolívar, Auyan-tepui; 2,300 m; VEN (holo).

Thibaudia breweri Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 378. 1976. *J. A. Steyermark et al. 109315*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,750–1,800 m; VEN (holo).

Thibaudia carrenoi Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 380. 1976. *J. A. Steyermark et al. 109298*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,750–1,800 m; VEN (holo).

Thibaudia dolichandra Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 180. 1978. *B. & C. K. Maguire 35149*; 11 Feb. 1953; Venezuela, T.F. Amazonas, Cerro Yutaje, Serranía Yutaje; 1,400 m; NY (holo).

Thibaudia jauaensis Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 383. 1976. *J. A. Steyermark et al. 109584*; 27 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 2,228–2,250 m; VEN (holo).

Thibaudia longipes Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 185. 1978. *B. Maguire et al. 29564*; 20 Nov. 1950; Venezuela, T.F. Amazonas, Cerro Duida; NY (holo).

Thibaudia smithiana Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 186. 1978. *B. Maguire & L. Politi 28349*; 14 Jan. 1949; Venezuela, T.F. Amazonas, Cerro Sipapo (Paraque); 1,815 m; NY (holo).

Vaccinium chimantense Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 189. 1978. *J. A. Steyermark & J. J. Wurdack 669*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,165–2,180 m; F, NY (holo), VEN.

Vaccinium haematinum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 139. 1944. *J. A. Steyermark 48572*; 14 July 1942; Guatemala, Dept. Huehuetenango, Cerro Huitz; 1,500–2,600 m; F (holo).

Vaccinium minarum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23: 219. 1947. *J. A. Steyermark 43295*; 26 Jan. 1942; Guatemala, Dept. Zacapa, Volcán Gemelos, Sierra de las Minas; 2,100–3,200 m; F (holo).

Vaccinium puberulum Klotzsch var. *jauaensis* Maguire, Steyerm. & Luteyn, Mem. New York Bot. Gard. 29(1): 192. 1978. *J. A. Steyermark 98054*; 22–27 Mar. 1967; Venezuela, Bolívar, Meseta de Jaua, Cerro Sarasariñama; 1,922–2,100 m; NY, VEN (holo).

ERIOCAULACEAE

Paepalanthus holstii Steyerm., Ann. Missouri Bot. Gard. 75: 311. 1988. *B. K. Holst 3523*; 22 May 1987;

Venezuela, Bolívar, Distr. Piar, Murisipán-tepui, summit; 2,300 m; MO (holo–3446413), VEN.

Paepalanthus meseticola Mold. & Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 281. 1976. *J. A. Steyermark et al. 109389*; 22–28 Feb. 1974; Venezuela, Bolívar, Cerro Jaua; Mold. Herbarium (holo). VEN.

Paepalanthus venetifolius Mold. & Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 284. 1976. *J. A. Steyermark et al. 109405*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta de Jaua, Cerro Jaua; 1,750–1,800 m; Mold. Herbarium (holo), VEN.

ERTHROXYLACEAE

Erthroxylon venezuelense Steyerm., Fieldiana Bot. 28(2): 271. 1952. *J. A. Steyermark 60371*; 20–21 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma, between Santa Teresita de Kavanayen and Río Pacairao; 1,065–1,220 m; F (holo) = *Erthroxylum mucronatum* Benth., 1966.

EUPHORBIACEAE

Amanoa pubescens Steyerm., Fieldiana Bot. 28(2): 304. 1952. *Ll. Williams 14439*; 20 Feb. 1942; Venezuela, T.F. Amazonas, Río Guainía; 128 m; F (holo).

Bernardia venezuelana Steyerm., Fieldiana Bot. 28(2): 306. 1952. *J. A. Steyermark 55603*; 27–28 Feb. 1944; Venezuela, Distr. Federal, Cordillera del Avila; F (holo).

Chaetocarpus williamsii Steyerm., Fieldiana Bot. 28(2): 306. 1952. *Ll. Williams 14312*; 12 Feb. 1942; Venezuela, T.F. Amazonas, Río Guainía, Maroa; 127 m; F (holo).

Conceveiba krukoffii Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 414. 1938. *B. A. Krukoff 8396*; 26 Oct.–11 Dec. 1936; Brazil, Amazonas, Mun. São Paulo de Olivenca, basin of Creek Belem, basin of Rio Solimões; MO (1253872), NY (holo) = *C. guianensis* Aublet, 1967.

Conceveiba magnifica Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 414. 1938. *B. A. Krukoff 8698*; 26 Oct.–11 Dec. 1936; Brazil, Amazonas, Mun. São Paulo de Olivenca, basin of Creek Belem, basin of Rio Solimões; MO (1250474), NU (holo).

Conceveiba simulata Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 416. 1938. *B. A. Krukoff 8616*; 26 Oct.–11 Dec. 1936; Brazil, Amazonas, Mun. São Paulo de Olivenca, basin of Creek Belem, basin of Rio Solimões; MO (1254141), NY (holo) = *C. guianensis* Aublet, 1967.

Conceveibastrum ptarianum Steyerm., Fieldiana Bot. 28(2): 308. 1952. *J. A. Steyermark 60021*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo) = *Conceveiba ptariana* (Steyerm.) Jabl., 1967.

Croizatia Steyerm., Fieldiana Bot. 28(2): 1952, gen nov.

Croizatia naiguatensis Steyerm., Brittonia 30(1): 40. 1978. *S. S. Tillett et al. 82*; 7 Dec. 1973; Venezuela, Distr. Federal, Cerro Naiguata; 2,000 m; DAV, VEN (holo).

Croizatia neotropica Steyerm., Fieldiana Bot. 28(2): 309. 1952. *J. A. Steyermark 61523*; 18 Mar. 1945; Venezuela, Anzoátegui, Quebrada Seca, E of Bergantín; F (holo).

Croton chamanus Steyerm., Fieldiana Bot. 28(2): 312. 1952. *J. A. Steyermark 56232*; 2 May 1944; Venezuela, Mérida, Río Chama, above Los González; 1,220–1,820 m; F (holo).

Croton croizatii Steyerm., Fieldiana Bot. 28(2): 312. 1952. *J. A. Steyermark 56124*; 26 Apr. 1944; Venezuela, Mérida, near Hacienda Agua Blanca; 975 m; F (holo).

Croton deserticolus Steyerm., Fieldiana Bot. 28(2): 313. 1952. *J. A. Steyermark 56821*; 28 May 1944; Venezuela, Lara, between Carora and Barquisimeto; 500 m; F (holo).

Croton douradensis Steyerm., Los Angeles Co. Mus. Contr. Sci. 21: 4. 1958. *E. Y. Dawson 14973*; n.d.; Brazil, Goiás, S Serra Dourada; F, LAM, R (holo).

Croton guaiquinimae Steyerm., Brittonia 32: 21. 1980; *J. A. Steyermark et al. 117473*; 26 May 1978; Venezuela, Bolívar, Cerro Guaiquinima; VEN (holo).

Croton huberi Steyerm., Brittonia 30: 41. 1978. *O. Huber. & A. Cleef 543*; 4 Mar. 1977; Venezuela, Distr. Federal, Parque Nacional El Avila; 2,000 m; VEN (holo).

Croton inaequilobus Steyerm.; Los Angeles Co. Mus. Contr. Sci. 21: 7. 1958. *E. Y. Dawson 14685*; 25 Apr. 1956; Brazil, Goiás, Chapada dos Veadeiros 14 mi. S of Veadeiros; F, LAM, R (holo).

Croton kavanayensis Steyerm., Fieldiana Bot. 28(2): 313. 1952. *J. A. Steyermark 60386*; 20–21 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma; 1,065–1,220 m; F (holo).

Croton larensis Steyerm., Fieldiana Bot. 28(2): 314. 1952. *J. A. Steyermark 56806*; 28 May 1944; Venezuela, Lara, between Trujillo–Lara boundary; 305 m; F (holo).

Croton roraimensis Croizat var. *subintegrus* Steyerm., Fieldiana Bot. 28(2): 315. 1952. *J. A. Steyermark 59925*; 7 Nov. 1944; Venezuela, Bolivar, Ptari-tepui; 2,410–2,450 m; F (holo) = *C. roraimensis* Croizat var. *roraimensis*.

Croton standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 151. 1940. *M. E. Davidson 892*; 12 July 1938; Panamá, Chiriquí, Distr. Boquete, Volcán Chiriquí; 2,100 m; F (holo), MO (1172438) = *C. pungens* Jacq., 1967.

Croton subincanus Muell. Arg. var. *guaiquinimensis* Steyerm., ined.?. *J. A. Steyermark et al. 113330*; 20–25 Jan. 1977; Venezuela, Bolívar, Cerro Guaiquinima, a lo largo del Río Szczerbanari (Río Carapo); MO (iso—2774296).

Croton sucrensis Steyerm., Fieldiana Bot. 28(2): 315. 1952. *J. A. Steyermark 62875*; 23 May 1945; Venezuela, Sucre, E of Cumana, near Quetepe, between km 18 and 20; 30 m; F (holo).

Croton turumiquirensis Steyerm., Fieldiana Bot. 28(2): 315. 1952. *J. A. Steyermark 62532*; 5 May 1945; Venezuela, Sucre, above La Trinidad SW of Cocollar; 2,100–2,200 m; F (holo).

Drypetes amazonica Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 420. 1938. *B. A. Krukoff 6210*; 14 Sep.–11 Oct. 1934; Brazil, Amazonas, basin of Rio Madeira, Mun. Humayta, near Tres Casas; F, NY (holo).

Euphorbia cuchumatanensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 169. 1944. *J. A. Steyermark 51646*; 30 Aug. 1942; Guatemala, Dept. Huehuetenango, Sierra de los Cuchumatanes; 800–1,200 m; F (holo).

Euphorbia guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 119. 1944. *P. C. Standley 80907*; 22 Dec. 1940; Guatemala, Dept. Chimaltenango, between Chimaltenango and San Martín Jilotepeque; 1,500–1,700 m; F (holo).

Euphorbia latazi H.B.K. var. *glabra* Steyerm., Fieldiana Bot. 28(2): 316. 1952. *J. A. Steyermark 55924*; 15 Apr. 1944; Venezuela, Mérida, Moconoque; 2,510 m; F (holo).

Euphorbia machrisiae Steyerm., Los Angeles Co. Mus. Contr. Sci. 21: 11. 1958. *E. Y. Dawson 14594*; 24 Apr. 1956; Brazil, Goiás, Chapada dos Ceadeiros, 7 km S of Veadeiros; F, LAM, R (holo).

Euphorbia pantomalaca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 120. 1944. *W. A. Kellerman 5175*; 10 Mar. 1905; Guatemala, Dept. Baja Verapaz, Sierra de las Minas, opposite El Rancho; F (holo).

Euphorbia senilis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 120. 1944. *J. A. Steyermark 50739*; 16 Aug. 1942; Guatemala, Dept. Huehuetenango, between San Ildefonso Ixtahuacán and Cuilco; 1,350–1,600 m; F (holo).

Euphorbia verapazensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 121. 1944. *C. L. Wilson 272*; 4 May 1939; Guatemala, Dept. Alta Verapaz, Río Chiacte; 480 m; F (holo).

Gymnanthes guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 122. 1944. *J. A. Steyermark 33501*; 5 Jan. 1940; Guatemala, Dept. Quezaltenango, S. Volcán Santa María; 1,300–1,400 m; F (holo).

"*Hieronyma*" *croizatii* Steyerm., Fieldiana Bot. 28(2): 317. 1952. *J. A. Steyermark 57005*; 25 June 1944; Venezuela, Distr. Federal, E of El Junquito; 1,980–2,130 m; F (holo). Note: *Hyeronima* is the correct spelling.

"*Hieronyma*" *oblonga* (Tul.) Muell. Arg. var. *genuina* Muell. Arg. f. *glabra* Steyerm., Fieldiana Bot. 28(4): 951. 1957. *J. A. Steyermark 60686*; 28 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo) = *Hyeronima oblonga* (Tul.) Muell. Arg. var. *oblonga*, 1967.

Jatropha standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 152. 1940. *E. Matuda 2260*; July 1936; Mexico, Oaxaca, Tehuantepec; F (holo).

Mabea elata Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 418. 1958. *G. Klug 3206*; Aug.–Sep. 1933; Perú, Loreto, between Balsapuerto and Moyobamba; 600–1,200 m; F (holo).

Mabea excelsa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 123. 1944. *A. F. Skutch 2008*; 27 Dec. 1934; Guatemala, Dept. Quezaltenango, Colombia; 850 m; F (holo).

Mabea klugii Steyerm., Field Mus. Nat. Hist., Bot Ser. 17(5): 416. 1938. *G. Klug 1969*; Jan.–Feb. 1931; Colombia, Comisaria del Putumayo, Umbria; F (holo).

Mabea pirioides Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 419. 1938. *B. A. Krukoff 1983*; 24 Oct. 1932; Brazil, Campo de Boa Esperanca, Maranhão, Maracassume River region; F (holo).

Mabea standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 17(5): 417. 1938. *G. Klug 2064*; Mar.–Apr. 1931; Perú, Dept. Loreto, Florida, Río Putumayo, at mouth of Río Zubineta; 200 m; F (holo).

Omphalea elaeophoroides Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 152. 1940. *B. A. Krukoff 6297*; 14 Sep.–11 Oct. 1934; Brazil, Amazonas, Piraninhon, Mun. Humayta, near Tres Casas, basin of Río Madeira; F, NY (holo).

Pedilanthus camporum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 124. 1944. *P. C. Standley 87781*; 18 Feb. 1941; Guatemala, Dept. Retalhuleu, between Nueva Linda and Champerico; 120 m; F (holo) = *P. tithymaloides* (L.) Poiteau.

Phyllanthus bolivarensis Steyerm., Fieldiana Bot. 28(2): 317. 1952. *J. A. Steyermark 57688*; 31 July–1 Aug. 1944; Venezuela, Bolívar, 1–10 km NW of Upata; 700 m; F (holo).

Phyllanthus carrenoi Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 343. 1976. *J. A. Steyermark et al. 109596*; 27 Feb. 1974; Venezuela, Bolívar, Cerro Jaua, Cumbre; 2,228–2,250 m; VEN (holo).

Phyllanthus croizatii Steyerm., Fieldiana Bot. 28(2): 317. 1952. *J. A. Steyermark 56854*; 29 May 1944; Venezuela, Yaracuy, near Taria; 75 m; F (holo).

Phyllanthus dawsonii Steyerm., Los Angeles Co. Mus. Contr. Sci. 21: 15. 1958, nom. nov.

Phyllanthus jablonskianus Steyerm. & Luteyn, Ann. Missouri Bot. Gard. 71: 317. 1984. *J. A. Steyermark 129816*; 8 Feb. 1984; Venezuela, T.F. Amazonas, Río Negro, Cerro de la Neblina; 1,880 m; MO (3223155), NY, VEN (holo).

Phyllanthus larensis Steyerm., Fieldiana Bot. 28(2): 318. 1952. *J. A. Steyermark 56813*; 28 May 1944; Venezuela, Lara between Trujillo–Lara boundary and Carora; 305 m; F (holo).

Phyllanthus longipes Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 153. 1940. *P. H. Gentle 2619*; 13 May 1938; Belize, El Cayo Distr., Vaca; F (holo), MICH.

Phyllanthus major Steyerm., Fieldiana Bot. 28(2): 318. 1952. *J. A. Steyermark 59482*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo).

Phyllanthus minarum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 125. 1944. *J. A. Steyermark 43385*; 4 Feb. 1942; Guatemala, Dept. El Progreso, Sierra de las Minas; 2,400–2,500 m; F (holo).

Phyllanthus orinocensis Steyerm., Fieldiana Bot. 28(2): 321. 1952. *J. A. Steyermark 57891*; 23 Aug. 1944; Venezuela, T.F. Amazonas, SE base of Cerro Duida; 210 m; F (holo).

Phyllanthus tepuicola Steyerm., Acta Bot. Venez. 10: 236. 1975. *M. Fariñas et al. 433*; Jan.–Feb. 1969; Venezuela, T.F. Amazonas, Cerro Duida; 1,000 m; VEN (holo).

Phyllanthus vacciniifolius (Muell. Arg.) Muell. Arg. var. *vinillaensis* Steyerm., Ann. Missouri Bot. Gard. 71: 317. 1984. *J. A. Steyermark et al. 130328*; 1 Mar. 1984; Venezuela, T.F. Amazonas, Serranía Vinilla, N of Cerro Aratitiyope; 440 m; VEN (holo).

Phyllanthus websterianus Steyerm., Los Angeles Co. Mus. Contr. Sci. 21: 17. 1958. *E. Y. Dawson 14918*; 17 May 1956; Brazil, Goiás, Serra Dourado, 20 km E of Formoso; F, G, LAM, R (holo).

Phyllanthus zanthoxyloides Steyerm., Fieldiana Bot. 28(2): 321. 1952. *J. A. Steyermark 62189*; 19 Apr. 1945; Venezuela, Monagas, Montaña de Aguacate; 600–900 m; F (holo).

Richeria submembranacea Steyerm., Field Mus. Nat. Hist., Bot. Ser 17(5): 419. 1938. *B. A. Krukoff 8513*; 11 Sep.–26 Oct. 1936; Brazil, Amazonas, Mun. São. Paulo de Olivenca, near Palmares, basin of Rio Solimões; NY (holo) = *R. racemosa* (Poepp. & Endl.) Pax & K. Hoffm., 1967.

Senefelderopsis Steyerm., Bot. Mus. Leafl. 15(2): 45. 1951, gen. nov.

Senefelderopsis croizatii Steyerm., Bot. Mus. Leafl. 15(2): 46. 1951. *J. A. Steyermark 60849*; 4–5 Dec. 1944;

Venezuela, Bolívar, Carrao-tepui, SE base; 1,460–1,615 m; F (holo).

Stillingia cruenta Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 125. 1944. *P. C. Standley 91207*; 4 Apr. 1941; Guatemala, Dept. Baja Verapaz, above Santa Rosa; 1,500 m; F (holo).

Tetrorchidium brevifolium Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 126. 1944. *C. L. Wilson 188*; 11 Feb. 1939; Guatemala, Dept. Alta Verapaz, Rubelpec; F (holo).

FABACEAE

Aeschynomene eriocarpa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 9. 1943. *J. A. Steyermark 29313*; 7 Oct. 1939; Guatemala, Zacapa, Santa Rosalía, 2 mi. S of Zacapa; 200 m; F (holo).

Aeschynomene tricholoma Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 10. 1943. *P. C. Standley 73714*; Oct. 1940; Guatemala, Dept. Chiquimula, near divide on road from Zacapa to Chiquimula; 660 m; F (holo).

Aldina berryi Cowan & Steyerm., Ann. Missouri Bot. Gard. 71: 312. 1984. *J. A. Steyermark et al. 117468*; 26 May 1978; Venezuela, Bolívar, Cerro Guaiquinima; 950 m; MO (3242295, 3234984), US, VEN (holo).

Apios americana Medic. f. *pilosa* Steyerm., Rhodora 40: 179. 1938. *J. A. Steyermark 11390*; 7 July 1936; U.S.A., Missouri, Butler Co., Clark National Forest, Wappapello Purchase Unit, Mud Creek, 2 mi. NW of Rombauer; MO (holo).

Calliandra carcerea Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 161. 1944. *J. A. Steyermark 42985*; 20 Jan. 1942; Guatemala, Dept. El Progreso, between Calera and Volcán Siglo; 2,000–2,200 m; F (holo).

Canavalia munda Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 10. 1943. *J. A. Steyermark 33179*; Dec. 1939; Guatemala, Dept. Quezaltenango, Finca Pirineos, Volcán Santa María; 1,300–1,500 m; F (holo).

Cassia fasciculata Michx. f. *jensenii* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 574. 1925. *L. P. Jensen s.n.*; 20 Aug. 1928; U.S.A., Missouri, Franklin Co. Gray Summit; MO (holo).

Cladrastis lutea (Michx. f.) Koch. f. *tomentosa* Steyerm., Rhodora 40: 487. 1938. *E. J. Palmer 35387*; 15 May 1929; U.S.A., Alabama, Tuscaloosa Co., along rocky bluffs of Black Warrior River, near lock 14; F (holo).

Climacorachis guatemala Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 11. 1943. *P. C. Standley 82330*; Jan. 1941; Guatemala, Dept. Huehuetenango, Río Pucal, 14 km S Huehuetenango; 1,800 m; F (holo).

Mimosa zacapana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 57. 1944. *J. A. Steyermark 29018*; Oct. 1939; Guatemala, Dept. Zacapa, near Santa Rosalia; 250–350 m; F (holo).

Pachecoa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 12. 1943, gen. nov.

Pachecoa guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 13. 1943. *P. C. Standley 75307*; Oct. 1940; Guatemala, Dept. Jutiapa, near Jutiapa; 850 m; F (holo).

Pithecolobium saxosum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 163. 1944. *P. C. Standley 74367*; 14 Oct. 1940; Guatemala, Dept. Chiquimula, Quebrada Shusho, above Chiquimula; 480 m; F (holo).

Pithecolobium zollerianum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 343. 1940. *J. A. Steyermark 37440*; 9 Mar. 1940; Guatemala, Dept. San Marcos, above Finca El Porvenir, up Loma Bandera Shac, Volcán Tajumulco; 1,300–1,500 m; F (holo).

Psoralea tenuiflora Pursh f. *alba* Steyerm., Rhodora 41: 585. 1939. *J. A. Steyermark 5779*; 3 June 1938; U.S.A., Missouri, Benton Co., along Osage River, 2.5 mi. W of Warsaw; MO (holo—1174669), F.

Rhynchosia jalapensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 57. 1944. *J. A. Steyermark 32945*; Dec. 1939; Guatemala, Dept. Jalapa, between Jalapa and San Pedro Pinula; 1,400 m; F (holo).

Swartzia cowanii Steyerm., Brittonia 33: 33. 1981. *J. A. Steyermark et al. 113463*; 22–24 Feb. (Jan. on label) 1977; Venezuela, Bolívar, Cerro Guaiquinima,

alrededores de Salto Szczerbanari, Río Szczerbanari (Río Caparo); MO (2775619); US, VEN (holo).

FAGACEAE

Quercus falcata Michx. f. *angustior* Palmer & Steyerm., Ann Missouri Bot. Gard. 25: 771. 1938. *J. A. Steyermark 12318*; 27 July 1936; U.S.A., Missouri, Oregon Co., along Eleven-Points River, 0.5 mi. N of McCormack Hollow, 3 mi. N of Greer; MO (holo).

Quercus × *inaequalis* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 521. 1935. *E. J. Palmer 16342*; 11 Sep. 1919; U.S.A., Missouri, Butler Co., Poplar Bluff; GH (holo). (*Q. phellos* × *Q. velutina*)

Quercus ×*mutabilis* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 521. 1935. *E. J. Palmer 26069*; 10 Sep. 1924; U.S.A., Missouri, Bates Co., Montieth Junction; GH (holo). (*Q. palustris* × *Q. shumardii* var. *schneckii*)

Quercus ×*vaga* Palmer & Steyerm., Ann Missouri Bot. Gard. 22: 521. 1935. *E. J. Palmer 25421*; 13 June 1924; U.S.A., Missouri, Nodaway Co., Maryville; GH (holo). (*Q. palustris* × *Q. velutina*)

FLACOURTIACEAE

Banara larensis Steyerm., Fieldiana Bot. 28(2): 404. 1952. *J. A. Steyermark 55424*; 10 Feb. 1944; Venezuela, Lara, between Las Sabanetas, Los Aposentos and Buenos Aires; 1,675–1,430 m; F (holo), K, NY, US.

Banara paucinervosa Steyerm., Fieldiana Bot. 28(2): 406. 1952. *J. A. Steyermark 55824*; 27 Mar. 1944; Venezuela, Mérida, above Las Cuadras along Quebrada Molino; 1,820–2,255 m; F (holo), NY, VEN = *Xylosma paucinervosa* (Steyerm.) Sleumer, 1980.

Bartholomaea Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 251. 1940, gen. nov.

Bartholomaea mollis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 252. 1940. *J. A. Steyermark 39452*; 27 Mar. 1939; Guatemala, Dept. Izabal, Río Dulce, near Livingston; F (holo).

Casearia tachirensis Steyerm., Fieldiana Bot. 28(2): 406. 1952. *J. A. Steyermark 57276*; 14 July 1944; Venezuela, Táchira, above Betania, at base of Páramo de Tamá; 2,285–2,430 m; F (holo), NY.

Euceraea sleumeriana Steyerm. & Maguire, Mem. New York Bot. Gard. 23: 870. 1972. *J. A. Steyermark 97851*; 22–27 Mar. 1967; Venezuela, Bolívar, Meseta de Jaua, Cerro Jaua; 1,922–2,100 m; L, NY, US, VEN (holo).

Hasseltia monagensis Steyerm., Fieldiana Bot. 28(2): 407. 1952. *J. A. Steyermark 61919*; 7 Apr. 1945; Venezuela, Monagas, Cerro de la Cueva de Dona Anita; 1,100–1,200 m; F (holo), NY, US, VEN = *H. floribunda* H.B.K., 1980.

Homalium anzoateguiensis Steyerm., Fieldiana Bot. 28(2): 410. 1952. *J. A. Steyermark 60993*; 20 Feb. 1945; Venezuela, Anzoátegui, along Río León by Quebrada Danta; 500 m; F (holo), L, NY, US, VEN = *H. racemosum* Jacq., 1980.

Ryania casiquiarensis Steyerm., Fieldiana Bot. 28(2): 411. 1952. *Ll. Williams 15564*; 25 May 1942; Venezuela, T.F. Amazonas, Capihuara, Alto Casiquiare; 118 m; A, F (holo), G, NY, US, VEN = *R. speciosa* Vahl. var. *tomentosa* (Miq.) Monachino, 1980.

Xylosma sessile Standl. & Steyerm., Field Mus Nat. Hist., Bot. Ser. 23(4): 177. 1944. *H. von Tuerckheim II.1617*; Jan. 1907; Guatemala, Dept. Alta Verapaz, Cobán; F (holo), US = *X. panamense* Turcz., 1980.

Xylosma trinervium Standl.& Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 178. 1944. *J. A. Steyermark 50876*; 18 Aug. 1942; Guatemala, Dept. Huehuetenango, along Río Cuilco, between Cuilco and San Juan; 1,200–1,300 m; F (holo) = *Neopringlei integrifolia* (Hemsley) S. Watson, 1980.

GARRYACEAE

Garrya corvorum Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(1): 16. 1943. *P. C. Standley 81651*; Dec. 1940; Guatemala, Dept. Huehuetenango, region of Chemal, Sierra de los Cuchumatanes at km 36; 3,300 m; F (holo).

GENTIANACEAE

Celiantha bella Maguire & Steyerm., Mem. New York Bot. Gard, 32: 383. 1981. *B. Maguire et al. 42096*; 19 Nov. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina; 1,800 m; NY (holo), US, VEN.

Centaurium rosans Standl. & Steyerm., Field Mus. Nat Hist., Bot. Ser. 23(2): 75. 1944. *J. A. Steyermark 34609*; Jan. 1940; Guatemala, Dept. Quezaltenango, Volcán Zunil; 2,500–3,000 m; F (holo) = *C. pauciflorum* (Mart. & Gal.) Rob., 1976.

Chorisepalum acuminatum Steyerm., Bol. Soc. Venez. Ci. Nat. 23: 75. 1962. *J. A. Steyermark & S. Nilsson 450*; 21 Apr. 1960; Venezuela, Bolívar, Cerro Venamo; 1,140 m; UP, VEN (holo) = *C. psychotroides* Ewan var. *acuminatum* (Steyerm.) Maguire, 1981.

Chorisepalum breweri Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 392. 1976. *J. A. Steyermark et al. 109255*; 19–20 Feb. 1974; Venezuela Bolívar, Meseta del Jaua, Cerro Sarasariñama; 1,350 m; VEN (holo).

Gentiana guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 75. 1944. *P. C. Standley 81113*; Dec. 1940; Guatemala, Dept. Huehuetenango, region Chemal, Sierra de los Cuchumatanes; 3,300 m; F (holo).

Gentiana lewisiae Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 76. 1944. *P.C. Standley 84556*; Guatemala, Dept. Totonicapán, Pacajá, region of El Desconsuelo; 3,100–3,200 m; F (holo).

Gentiana pumilio Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 76. 1944. *J. A. Steyermark 35489*; Feb. 1940. Guatemala, Dept. San Marcos, between San Sebastián and summit of Volcán Tajumulco; 4,000 m; F (holo).

Lisianth[*i*]*us acutilobus* Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 439. 1966. *J. A. Steyermark & S. Nilsson 732*; 25 Apr. 1960; Venezuela, Bolívar, Río Aponguao at km 146; 1,220 m; VEN (holo) = *Irlbachia cardonae* (Gleason) Maguire, 1981. Note: *Lisianthius* is the correct spelling.

Lisianth[*i*]*us calciphilus* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 267. 1940. *C. L. Wilson 356*; 22 Mar. 1939; Guatemala, Dept. Alta Verapaz, Finca Los Alpes; 1,200 m; F (holo) = *Lisianthius brevidentatus* (Hemsl.) O. Kuntze, 1969.

Lisianth[*i*]*us chimantensis* Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 461. 1967. *J. A. Steyermark & J. J. Wurdack 374-A*; 3 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Summit Camp; 1940

m; NY (holo) = *Celiantha chimantensis* (Steyerm. & Maguire) Maguire, 1981.

Lisianth[i]us elatus Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 267. 1940. *J. A. Steyermark 38526*; 1 Apr. 1940; Guatemala, Dept. Izabal, between Milla 49.5 and ridge 6 mi. from Izabal, Montaña del Mico; 65–600 m; F (holo).

Lisianth[i]us jauaensis Steyerm. & Maguire, Mem. New York Bot. Gard. 23: 879. 1972. *J. A. Steyermark 98068*; 22–27 Mar. 1967; Venezuela, Bolívar, Cerro Jaua; 1,922–2,100 m; VEN (holo).

Lisianth[i]us petenensis Standl. & Steyerm., Bull. Torrey Bot. Club 84(1): 46. 1957. *C. H. Lundell 3153*; 4 May 1933; Guatemala, Dept. Petén, Nicton, Lake Petén; US (holo).

Lisianth[i]us scabridulus Steyerm., Fieldiana Bot. 28(3): 496. 1953. *J. A. Steyermark 57979*; 25–26 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,200 m; F (holo) = *Irlbachia tatei* (Gleason) Maguire, 1981.

Macrocarpaea neblinae Maguire & Steyerm., Mem. New York Bot. Gard. 32: 332. 1981. *B. Maguire et al. 37103*; 6 Jan. 1954; Venezuela, T.F. Amazonas, Cerro de la Neblina; 2,000 m; NY (holo).

Macrocarpaea rugosa Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 83. 1963. *J. A. Steyermark, & J. J. Wurdack 861*; 13 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,185–2,210 m; C, NY, VEN (holo).

Schultesia guianensis (Aublet) Malme f. *lutescens* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 77. 1944. *P. C. Standley 76561*; Nov. 1940; Guatemala, Dept. Jalapa, near Jalapa; 1,360 m; F (holo).

Symbolanthus aracamuniensis Steyerm., Ann. Missouri Bot. Gard.: in press. 1989. *R. L. Liesner & F. Delascio 22079*; 17 Oct. 1987; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp; 1,550 m; MO (holo), VEN.

Symbolanthus huachamacariensis Steyerm., Ann. Missouri Bot. Gard. 75: 1083. 1988. *B. Maguire et al. 29859*; 4 Dec. 1950; Venezuela, T.F. Amazonas, Cerro Huachamacari; 1,700 m; NY, VEN (holo).

Symbolanthus sessilis Steyerm. & Maguire, Mem. New York Bot. Gard. 23: 879. 1972. *J. A. Steyermark 97958*; 22–27 Mar. 1967; Venezuela, Bolívar, Cerro Jaua; 1,922–2,100 m; NY, VEN (holo).

Symbolanthus yaviensis Steyerm., Ann. Missouri Bot. Gard. 75: 1084. 1988. *O. Huber 11849*; 24 Oct. 1986; Venezuela, T.F. Amazonas, Dept. Atures, summit of Cerro Yaví; 100 m; MO (holo), VEN.

Tapeinostemon breweri Steyermark & Maguire, Acta Bot. Venez. 14(3): 42. 1984. *B. Maguire et al. 65593*; 15 Jan. 1981; Venezuela, T.F. Amazonas, Cerro Marahuaca; 2,685; m; K, MG, MO, NY, US, VEN (holo).

Tapeinostemon jauaensis Steyerm. & Maguire, Bol. Soc. Venez. Ci. Nat. 32: 394. 1976. *J. A. Steyermark et al. 109535*; 26 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,800 m; VEN (holo).

Tapeinostemon longiflorum Maguire & Steyerm., Mem. New York Bot. Gard. 32: 359. 1981. *B. Maguire et al. 42134*; 17 Nov. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina; 1,800 m; K, NY (holo), US, VEN.

Tapeinostemon longiflorum Maguire & Steyerm. var. *australe* Maguire & Steyerm., Mem. New York Bot. Gard. 32: 362. 1981. *J. A. Steyermark 103937*; 16–17 Oct. 1970; Venezuela, Cerro de la Neblina; NY (holo), VEN.

Tapeinostemon ptariense Steyerm., Lloydia 14(1): 61. 1951. *J. A. Steyermark 59861*; 4 Nov. 1944; Venezuela, Bolívar, Ptari-tepui, E. of 'Cave Rock'; 213 m; F (holo) = *T. spenneroides* Benth., 1981.

Tapeinostemon rugosum Maguire & Steyerm., Mem. New York Bot. Gard. 32: 366. 1981. *J. A. Steyermark & J. J. Wurdack 1227*; 1 Mar. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; NY (holo), VEN.

Tapeinostemon zamoranum Steyerm., Lloydia 14(1): 63. 1951. *J. A. Steyermark 54560*; 10 Oct. 1943; Ecuador, Prov. Santiago-Zamora, vicinity of Rancho Achupallas, along Quebrada Honda; 2,500–2,700 m; F (holo).

Voyria allenii Steyerm., Ann. Missouri Bot. Gard. 28: 460. 1941. *P. H. Allen 2240*; Panama, Coclé, N of El Valle de Antón; F (holo) = *V. truncata* (Standl.) Standl. & Steyerm., 1969.

GESNERIACEAE

Besleria mortoniana Steyerm., Brittonia 22: 303. 1970. *J. A. Steyermark 94962*; 3 Mar. 1966; Venezuela, Sucre, Peninsula de Paria, Cerro de Humo; 1,060–1,273 m; US (holo), VEN.

Solenophora abietorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 236. 1947. *J. A. Steyermark 48643*; 14 July 1942; Guatemala, Dept. Huehuetenango, Cerro Huitz, Sierra de los Cuchumatanes; 1,500–2,600 m; F (holo).

GRAMINEAE see Poaceae

GROSSULARIACEAE

Phyllonoma cacuminis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 335. 1940. *J. A. Steyermark 29870*; 13 Oct. 1939; Guatemala, Dept. Zacapa, Quebrada Alejandría, summit of Sierra de las Minas, vicinity of Finca Alejandría; 2,500 m; F (holo).

GUNNERACEAE

Gunnera pittieriana Badillo & Steyerm., Acta Bot. Venez. 8: 311. 1973. *V. M. Badillo 4866*; 18 June 1972; Venezuela, Aragua, Parque Nacional Henri Pittier, Alto de Choroni; MY (holo).

GUTTIFERAE = CLUSIACEAE

HELICONIACEAE

Heliconia schneeana Steyerm., Fieldiana Bot. 28(1): 161. 1951. *J. A. Steyermark 56083*; 25 Apr. 1944; Venezuela, Mérida, above La Azulita, Hacienda Agua Blanca; 1,310–1,340 m; F (holo).

HUMIRIACEAE

"*Houmiria*" *pilosa* Steyerm., Fieldiana Bot. 28(2): 270. 1952. *J. A. Steyermark 60289*; 15–17 Nov. 1944; Venezuela, Bolívar, between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo). Note: *Humiria* is the correct spelling.

HYDROPHYLLACEAE

Hydrophyllum appendiculatum Michx. f. *album* Steyerm., Rhodora 54: 257. 1952. *J. A. Steyermark 67519*; 19 May 1949; U.S.A., Missouri, Johnson Co., Knobnoster State Park, 3–5 mi. SW of Knobnoster; F (holo).

Phacelia hirsuta Nutt. f. *albiflora* Palmer & Steyerm.,

Brittonia 10: 116. 1958. *E. J. Palmer 65070*; 15 May 1957; U.S.A., Missouri, Newton Co., 1 mi. S of Granby; F (holo).

HYPERICACEAE = Clusiaceae

ICACINACEAE

Emmotum ptarianum Steyerm., Fieldiana Bot. 28(2): 341. 1952. *J. A. Steyermark 59974*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo) = *E. glabrum* Benth. ex Miers, 1978.

Oecopetalum greenmanii Standl. & Steyerm.; Field. Mus. Nat. Hist., Bot. Ser. 22(3): 154. 1940. *J. A. Steyermark 39516*; 16 Apr. 1940; Guatemala, Dept. Izabal, Río Dulce, 2–4 mi. W of Livingston; sea level; F (holo).

IRIDACEAE

Orthrosanthus chimboracensis (H.B.K.) Baker var. *acorifolius* (H.B.K.) Steyerm. f. *albus* Steyerm., Lloydia 11(1): 19. 1948. *J. A. Steyermark 55339a*; n.d.; Venezuela, Trujillo, La Quebrada Cortijo above Humocaro Bajo; F (holo) = *O. acorifolius* (Kunth) Ravenna, 1987.

Orthrosanthus chimboracensis (H.B.K.) Baker var. *centroamericanus* Steyerm., Lloydia 11(1): 17. 1948. *J. A. Steyermark 31913*; n.d.; Guatemala, Jutiapa, Volcán Suchitán, NW of Asunción Mita; F (holo).

Orthrosanthus chimboracensis (H.B.K.) Baker var. *exsertus* Foster f. *albus* Steyerm., Lloydia 11(1): 17. 1948. *Runyon 875*; 8 Apr. 1926; Mexico, Tamaulipas, Santa Rita, Ranch Tamaulipas; 1,500 m; US (holo) = *O. exsertus* (Foster) Ravenna, 1987.

Orthrosanthus chimboracensis (H.B.K.) Baker var. *intermedius* Steyerm., Lloydia 11(1): 19. 1948. Type not indicated.

Trimezia chimantensis Steyerm., Ann. Missouri Bot. Gard. 71: 301. 1984. *J. A. Steyermark et al. 128071*; 26–29 Jan. 1983; Venezuela, Bolívar, Distr. Piar, Macizo de Chimantá, sector centro-noreste del Chimantá-tepui; 2,000 m; VEN (holo).

Trimezia fosteriana Steyerm. Fieldiana Bot. 28(1): 160. 1951. *J. A. Steyermark 60834*; 4 Dec. 1944; Venezuela, Bolívar, Río Tek-Yunsen between Santa Teresita de Kavanayen and Carrao-tepui; 1,375 m; F (holo).

IXONANTHACEAE

Ochthocosmus attenuatus Steyerm. & Luteyn, Brittonia 32: 142. 1980. *J. A. Steyermark et al. 117570*; 15–16 Nov. 1978; Venezuela, Bolívar, near San Rafael de Camoiran, km 175 S of El Dorado; 1,090 m; NY (holo), VEN.

Ochthocosmus berryi Steyerm., Ann. Missouri Bot. Gard. 71: 313. 1984. *J. A. Steyermark et al. 130228*; 26 Feb. 1984; Venezuela, T.F. Amazonas, Cerro Aratitiyope; MO (3223161), VEN (holo).

Ochthocosmus grandifolius Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 421. 1966. *J. A. Steyermark et al. 92379*; 29–30 Dec. 1963; Venezuela, Bolívar, Cerro Venemo; 950–1,150 m; VEN (holo) = *O. roraimae* var. *grandifolius* (Steyerm.) Steyerm. & Luteyn, 1980.

Ochthocosmus longipedicellatus Steyerm. & Luteyn, Brittonia 32: 141. 1980. *J. A. Steyermark et al. 117569*; 15–18 Nov. 1978; Venezuela, Bolívar, km 175 S of El Dorado, near San Rafael de Camoiran; 1,090 m; NY, VEN (holo).

Ochthocosmus micranthus Steyerm., Ann. Missouri Bot. Gard 75: 318. 1988. *L. Hernández 348*; 13 Nov. 1986; Venezuela, Bolívar, Ayavaparú, 10 km SW of Wadacapiae; 1,100 m; MO, VEN (holo).

Ochthocosmus multiflorus Ducke var. *angustifolius* Steyerm. & Luteyn, Brittonia 32: 141. 1980. *B. Maguire et al. 30557*; 1 Jan. 1951; Venezuela, T.F. Amazonas, NW base Cerro Yapacana, Savanna No. 3; 125 m; NY, US, VEN (holo).

Ochthocosmus multiflorus Ducke var. *canaripoensis* Steyerm. & Luteyn, Brittonia 32: 141. 1980. *J. A. Steyermark et al. 113837*; 2 Mar. 1977; Venezuela, T.F. Amazonas, Canaripo, lado sur del Río Ventuari; 125 m; F, NY, VEN (holo).

JUGLANDACEAE

Carya buckleyi Sarg. var. *arkansana* Sarg. f. *glabra* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 770. 1938. *J. A. Steyermark 11461*; 8 July 1936; U.S.A., Missouri, Butler Co., near Cane Creek, off N Fork Hollow, 10 mi. SE of Ellsinore; MO (holo—1130651) = *C. texana* Buckl. var. *texana*, 1981.

LAMIACEAE

Scutellaria nervosa Pursh f. *alba* Steyerm., Rhodora 54: 257. 1952. *J. A. Steyermark 68024*; 21 May 1949; U.S.A., Missouri, Chariton Co., along Yellow Creek, near Rothville; F (holo).

LAURACEAE

Benzoin aestivale (L.) Nees var. *pubescens* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 545. 1935. *E. J. Palmer 21923*; 12 Sep. 1922; U.S.A., Missouri, Jasper Co., Alba; GH (holo) = *Lindera benzoin* (L.) Blume, 1981.

Ocotea laetevirens Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 114. 1944. *J. A. Steyermark 49189*; July 1942; Guatemala, Dept. Huehuetenango, Cerro Chiblac; 1,200–2,000 m; F (holo).

Ocotea verapazensis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 114. 1944. *P. C. Standley 71421*; Apr. 1939; Guatemala, Dept. Alta Verapaz, Tactic; 1,480 m; F (holo).

Persea sessilis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 115. 1944. *J. A. Steyermark 42487*; 12–13 Jan. 1942; Guatemala, Dept. Zacapa, Sierra de las Minas; 2,100–2,400 m; F (holo).

Persea vesticula Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 116. 1944. *J. A. Steyermark 36207*; 20 Feb. 1940; Guatemala, Dept. San Marcos, Volcán Tacaná; 2,500–3,000 m; F (holo).

Phoebe macrophylla Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 116. 1944. *P. C. Standley 70009*; Mar. 1939; Guatemala, Dept. Alta Verapaz, SE of Tactic; 1,500 m; F (holo) = *Ocotea standleyi* Allen, 1946.

Phoebe padiformis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 117. 1944. *A. F. Skutch 1367*; Oct. 1934; Guatemala, Dept. Quezaltenango, Colomba; 575 m; F (holo).

Phoebe savannarum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(3): 118. 1944. *J. A. Steyermark 45712*; Apr. 1942; Guatemala, Dept. Alta Verapaz, Cerro Chinajá at Sachaj and Sacacao; 150–180 m; F (holo).

LECYTHIDACEAE

Lecythis karuaiensis Steyerm., Fieldiana Bot. 28(2): 422. 1952. *J. A. Steyermark 60767*; 29 Nov. 1944; Venezuela, Bolívar, base of Sororopan-tepui; 1,220 m; F (holo), MO (1621335) = *L. alutacea* (A. C. Smith) Mori, 1988.

LEGUMINOSAE = Fabaceae

LENNOACEAE

Lennoa madreporoides Llave & Lex subsp. *australis* Steyerm., Acta Bot. Venez. 3: 230. 1968. *J. A. Steyermark & A. Braun 94518*; 23 Jan. 1966; Venezuela, Falcón, Peninsula de Paraguaná, N of Coro; MO (1897510), NY, US, VEN (holo) = *L. madreporoides* Lexarza var. *madreporoides*, 1970.

LENTIBULARIACEAE

Genlisea esmeraldae Steyerm., Fieldiana Bot. 28(3): 534. 1953. *J. A. Steyermark 57835a*; 22 Aug. 1944; Venezuela, T.F. Amazonas; SE base of Cerro Duida; 200 m, F (holo) = *G. pygmaea* St. Hiliare, 1967.

Genlisea nigrocaulis Steyerm., Bull. Torrey Bot. Club 75(6): 657. 1948. *J. A. Steyermark 59644*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo) = *G. pygmaea* St. Hiliare, 1967.

Genlisea sanariapoana Steyerm., Fieldiana Bot. 28(3): 534. 1953. *J. A. Steyermark 58445*; 8 Sep. 1944; Venezuela, T.F. Amazonas, below mouth of Río Sanariapo, along Orinoco River; 100 m; F (holo).

Pinguicula clivorum Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 179. 1944. *J. A. Steyermark 50061*; 4 Aug. 1942; Guatemala, Dept. Huehuetenango, above San Juan Ixcoy, Sierra de los Cuchumatanes; 2,400 m; F (holo) = *P. lilacina* Schlecht & Cham., 1974.

Utricularia amazonasana Steyerm., Fieldiana Bot. 28(3): 535. 1953. *J. A. Steyermark 58505*; 8 Sep. 1944; Venezuela, T.F. Amazonas, vicinity of Sanariapo; 100 m; F (holo) = *U. hydrocarpa* Vahl, 1967.

Utricularia arenicola Tutin var. *kavanayena* Steyerm., Fieldiana Bot. 28(3): 535. 1953. *J. A. Steyermark 59335*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo) = *U. nana* St. Hiliare & Girard, 1967.

Utricularia aureolimba Steyerm., Fieldiana Bot. 28(3): 535. 1953. *J. A. Steyermark 59351*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo) = *U. adpressa* Salzmann, 1967.

Utricularia aureomaculata Steyerm., Fieldiana Bot. 28(3): 536. 1953. *J. A. Steyermark 59852*; 4 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,130 m; F (holo).

Utricularia ayacuchae Steyerm., Fieldiana Bot. 28(3): 538. 1953. *J. A. Steyermark 58520*; 11 Sep. 1944; Venezuela, T.F. Amazonas, Puerto Ayacucho; 200 m; F (holo) = *U. cucullata* St. Hiliare & Girard, 1967.

Utricularia baldwinii Steyerm., Bull. Torrey Bot. Club 79(4): 310. 1952. *J. T. Baldwin, Jr. 4077*; 3 June 1944; Brazil, Terr. Amapá, Amapá; US (holo) = *U. amethystina* St. Hiliare & Girard, 1967.

Utricularia bolivarana Steyerm., Fieldiana Bot. 28(3): 538. 1953. *J. A. Steyermark 59191*; 3 Oct. 1944; Venezuela, Bolívar, S of Mt. Roraima, Gran Sabana; 1,065 m; F (holo) = *U. amethystina* St. Hiliare & Girard, 1967.

Utricularia campbelliana Oliver var. *minor* Steyerm., Fieldiana Bot. 28(3): 539. 1953. *J. A. Steyermark 59753*; 2 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,000–2,200 m; F (holo) = *U. campbelliana* Oliv. var. *campbelliana*, 1967.

Utricularia cearana Steyerm., Bull. Torrey Bot. Club 79(4): 310. 1952. *H. C. Cutler 8365*; 10 June 1952; Brazil, Ceara, 4 km N of Soure (Caucaia); F (holo).

Utricularia congesta Steyerm., Fieldiana Bot. 28(3): 539. 1953. *J. A. Steyermark 59404*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo) = *U. fimbriata* Kunth, 1967.

Utricularia congesta Steyerm. f. *diminutiva* Steyerm., Fieldiana Bot. 28(3): 540. 1953. *J. A. Steyermark 59195*; 3 Oct. 1944; Venezuela, Bolívar, S of Mt. Roraima, Gran Sabana; 1,065 m; F (holo).

Utricularia cuspidata Steyerm., Fieldiana Bot. 28(3): 542. 1953. *J. A. Steyermark 60119*; 14 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,255 m; F (holo) = *U. calycifida* Benjamin, 1967.

Utricularia cutleri Steyerm., Bull. Torrey Bot. Club 79(4): 311. 1952. *H. C. Cutler 8363*; 10 June 1945; Brazil, Ceara, 4 km N of Soure (Caucaia); F (holo) = *U. viscosa* Spruce ex Oliver, 1967.

Utricularia dawsonii Steyerm., Los Angeles Co. Mus. Contr. Sci. 21: 20. 1958. *E. Y. Dawson 14770*; 1 May 1956; Brazil, Golás, Chapada dos Veadeiros, 10 km from Veadeiros on Cavalcante road; F (holo), LAM, R = *U. amethystina* St. Hiliare & Girard, 1967.

Utricularia heterochroma Steyerm., Fieldiana Bot. 28(3): 544. 1953. *J. A. Steyermark 59930*; 7 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,410–2,450 m; F (holo).

Utricularia humboldtii Schomb. f. *cuneata* Steyerm., Fieldiana Bot. 28(3): 544. 1953. *J. A. Steyermark 58229*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,025–1,200 m; F (holo) = *U. humboldtii* R. H. Schomb. var. *humboldtii*, 1967.

Utricularia kaieteurensis Steyerm., Bull. Torrey Bot. Club 75(6): 658. 1948. *B. Maguire & D. B. Fanshawe 23204*; 4 May 1944; Guyana, Kaieteur Plateau; F (holo), NY = *U. amethystina* St. Hiliare & Girard, 1967.

Utricularia maguirei Steyerm., Bull. Torrey Bot. Club 75(6): 659. 1948. *B. Maguire & D. B. Fanshawe 23249*; 5 May 1944; Guyana, Kaieteur Plateau; F (holo), NY = *U. calycifida* Benjamin, 1967.

Utricularia oliveriana Steyerm., Fieldiana Bot. 28(3): 546. 1953. *J. A. Steyermark 58446*; 8 Sep. 1944; Venezuela, T.F. Amazonas, below mouth of Río Sanariapo, along Orinoco River; 100 m; F (holo).

Utricularia oliveriana Steyerm. f. *parva* Steyerm., Fieldiana Bot. 28(3): 546. 1953. *J. A. Steyermark 59333*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo) = *U. oliveriana* Steyerm. var. *oliveriana*, 1967.

Utricularia orinocensis Steyerm., Fieldiana Bot. 28(3): 548. 1953. *J. A. Steyermark 58488*; 8 Sep. 1944; Venezuela, T.F. Amazonas, Sanariapo; 100 m, F (holo) = *U. fimbriata* Kunth, 1967.

Utricularia subpeltata Steyerm., Fieldiana Bot. 28(3): 548. 1953. *J. A. Steyermark 60477*; 23 Nov. 1944; Venezuela, Bolívar, between Santa Teresita de Kavanayen and ca. 8 km NW of Kavanayen; 1,220 m; F (holo) = *U. pubescens* Smith in Rees, 1967.

Utricularia tepuiana Steyerm., Fieldiana Bot. 28(3): 550. 1953. *J. A. Steyermark 59517*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo) = *U. amethystina* St. Hiliare & Girard, 1967.

Utricularia turumiquirensis Steyerm., Fieldiana Bot. 28(3): 552. 1953. *J. A. Steyermark 62752*; 11 May 1945; Venezuela, Sucre, between base of Cerro de Diablo and Cerro de Neveri, along headwaters of Río de Amana; 2,000 m; F (holo) = *U. amethystina* St. Hiliare & Girard, 1967.

Utricularia venezuelana Steyerm., Fieldiana Bot. 28(3): 552. 1953. *J. A. Steyermark 59625a*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo) = *U. pubescens* Smith in Rees, 1967.

Utricularia williamsii Steyerm., Ceiba 1: 126. 1950. *Ll. Williams 10639*; 17 Oct. 1946; Honduras, Dept. Morazán, near Hoya Grande, drainage of Río Yeguare; 1,500 m; F (holo) = *U. amethystina* St. Hiliare & Girard, 1967.

LILIACEAE

Camassia scilloides (Raf.) Cory f. *petersenii* Steyerm., Rhodora 40: 178. 1938. *J. A. Steyermark 22499*; 23 Apr. 1937; U.S.A., Missouri, St. Louis Co., Osage Hills, MO (holo—1174671).

Camassia scilloides (Raf.) Cory f. *variegata* Steyerm., Rhodora 51: 116. 1949. *J. A. Steyermark 28324*; 25 Apr. 1941; U.S.A., Missouri, Christian Co., Pedelo Creek, 4.5. mi. NE of Sparta; F (holo).

Excremis coarctata (Ruíz & Pavón) Baker f. *alba* Steyerm., Fieldiana Bot. 28(1): 153. 1951. *J. A. Steyermark 62963*; 16–17 June 1945; Venezuela, Miranda, above Los Chorros, Pico de Naiguata; 2,200–2,765 m; F (holo).

Nietneria paniculata Steyerm., Fieldiana Bot. 28(1): 153. 1951. *J. A. Steyermark 59362*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

Smilacina crassipes Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(5): 214. 1947. *J. A. Steyermark 51003*; 20 Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Pueblo Viejo; 1,900 m; F (holo) = *Maianthemum gigas* var. *crassipes* (Standl. & Steyerm.) LaFrankie, 1986.

Tofieldia duidae Steyerm., Fieldiana Bot. 28(1): 156. 1951. *J. A. Steyermark 58716*; 1 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida, Brocchinia Hills; 1,700–1,980 m; F (holo).

Tofieldia sessiliflora Hook. var. *robustior* Steyerm., Fieldiana Bot. 28(1): 157. 1951. *J. A. Steyermark 55291*; 5 Feb. 1944; Venezuela, Lara, Las Sabanetas, above Los Aposentos, W of Humocaro Bajo; 2,530 m; F (holo).

Trillium ozarkanum Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 504. 1935. *J. A. Steyermark 18628*; 20 Apr. 1935; U.S.A., Missouri, Barry Co., 3 mi. S of Cassville; MO (holo) = *T. pusillum* Michx. var. *ozarkanum* (Palmer & Steyerm.) Steyerm., 1960.

Trillium recurvatum Beck f. *foliosum* Steyerm., Rhodora 61: 124. 1959. *W. Adams s.n.*; 6 Apr. 1949; U.S.A., Missouri, Cape Girardeau Co., Houck Woods, Bloomfield Road; SE Missouri State College (holo).

Trillium recurvatum Beck f. *petaloideum* Steyerm., Rhodora 61: 124. 1959. *W. Adams s.n.*; 6 Apr. 1949; U.S.A., Missouri, Cape Girardeau Co., Houck Woods, Bloomfield Road; SE Missouri State Univ. (holo).

Trillium recurvatum Beck f. *shayi* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 504, 1935, nom. nov.

LIMNOCHARITACEAE

"*Hydrocleis*" *standleyi* Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 31. 1944. *J. A. Steyermark 30416*; Oct. 1939; Guatemala, Dept. Jutiapa, between Agua Blanca and Amatillo; 950 m; F (holo). Note: *Hydrocleys* is the correct spelling.

LINACEAE

Ochthocosmus see under Ixonanthaceae

LISSOCARPACEAE

Lissocarpa stenocarpa Steyerm., Ann. Missouri Bot. Gard. 74: 104. 1987. *J. A. Steyermark & B. K. Holst 130880*; 28 Feb.–1 Mar. 1985; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca; 1,140 m; MO (holo—3327360), VEN.

LOASACEAE

"*Cajaphora*" *larensis* Steyerm., Fieldiana Bot. 28(2): 412. 1952. *J. A. Steyermark 55528*; 12 Feb. 1944; Venezuela, Lara, between Buenos Aires to Canyon of El Callado, above Humocaro Alto; 2,285–2,740 m; F (holo). Note: *Caïophora* is the correct spelling.

"*Cajaphora*" *venezuelensis* Steyerm., Fieldiana Bot. 28(2): 414. 1952. *J. A. Steyermark 56594*; 18 May 1944; Venezuela, Mérida, La Isla, above Tabay; 2,285–2,745 m; F (holo).

Eucnide guatemalensis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 178. 1944. *J. A. Steyermark 50818*; 17 Aug. 1942; Guatemala, Dept. Huehuetenango, NW of Cuilco, Cerro Chiquihui, above Carrizal; 2,000 m; F (holo).

Schismocarpus matudai Steyerm., Bull. Torrey Bot. Club 80(2): 138. 1953. *E. Matuda 5330*; Mexico, Chiapas, along Río Cintalapa, between Jilquero and Piñuela, Mun. Escuintla; 500 m; Matuda Herbarium (holo).

LOGANIACEAE

"*Buddleia*" *amplexicaulis* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 71. 1944. *P. C. Standley 65479*; 17 Feb. 1939; Guatemala, Dept. Quezaltenango, El Chorro, near Zunil; F (holo) = *Buddleja crotonoides* A. Gray, 1969. Note: *Buddleja* is the correct spelling.

"*Buddleia*" *australis* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 72. 1944. *J. A. Steyermark 37276*; 8 Mar. 1940; Guatemala, Dept. San Marcos, Loma de la Paloma, above Finca El Porvenir, Volcán Tajamulco; 1,400–1,700 m; F (holo) = *Buddleja cordata* H.B.K., 1969.

"*Buddleia*" *euryphylla* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(5): 223. 1947. *J. A. Steyermark 43628*; 7 Feb. 1942; Guatemala, Dept. El Progreso, Sierra de las Minas, Joya Pacayal; 2,500-3,000 m; F (holo).

"*Buddleia*" *stenoptera* Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 71. 1944. *J. A. Steyermark 35001*; 24 Jan. 1940; Guatemala, Dept. Quezaltenango, in Río Samalá, below Zunil; 2,500 m; F (holo) = *Buddleja crotonoides* A. Gray, 1969.

Spigelia carnosa Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 72. 1944. *J. A. Steyermark 48692*; 15 July 1942; Guatemala, Dept. Huehuetenango, between Yulhuitz and Maxbal, Sierra de los Cuchumatanes; 1,400–1,500 m; F (holo).

LORANTHACEAE

Phthirusa hippocrateoides Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 442. 1967. *J. A. Stey-*

ermark 75059; 17 Apr. 1953; Venezuela, Bolívar, Abacapa-tepui, Chimantá Massif; 1,312–1,500 m; NY (holo) = *Struthanthus syringifolius* Mart., 1982.

Phthirusa ptariana Steyerm., Fieldiana Bot. 28(1): 225. 1951. *J. A. Steyermark 59549*; 30 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 2,100–2,285 m; F (holo) = *Struthanthus syringifolius* Mart., 1982.

Phthirusa roraimensis Steyerm., Fieldiana Bot. 28(1): 224. 1951. *J. A. Steyermark 58943*; 30 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 2,040–2,255 m; F (holo).

Psittacanthus costanensis Steyerm., Acta Bot. Venez. 3: 189. 1968. *J. A. & C. Steyermark 95215*; 28 Mar. 1966; Venezuela, Carabobo, Río San Gian, S Borburata, La Toma; 750–1,000 m; NY, US, VEN (holo).

Psittacanthus mayanus Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 41. 1944. *P. Gentle 116*; 14 Sep. 1933; Belize, Santa Rita; F (holo).

Struthanthus brachybotrys Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 42. 1944. *P. C. Standley 82430*; Jan. 1941; Guatemala, Dept. Huehuetenango, Río Pucal ca. 14 km S of Huehuetenango; 1,790 m; F (holo).

Struthanthus chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 443. 1967. *J. A. Steyermark 74816*; 5 Apr. 1953; Venezuela, Bolívar, Abacapa-tepui, Chimantá Massif; 750–1,100 m; MO (201171), VEN (holo) = *S. gracilis* (Gleason) Steyerm. & Maguire, 1967.

Struthanthus johnstonii Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 43. 1944. *J. R. Johnston 1887*; 2 Jan. 1941; Guatemala, Dept. Huehuetenango, W of Aguacatán; F (holo).

Struthanthus mucronatus Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 418. 1966. *J. A. Steyermark et al. 92336*; 29–30 Dec. 1963; Venezuela, Bolívar, Cerro Venamo; 950–1,150 m; VEN (holo) = *S. gracilis* (Gleason) Steyerm. & Maguire var. *mucronatus* (Steyerm.) Rizz., 1982.

Struthanthus oliganthus Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 154. 1944. *J. A. Steyermark 50672*; 15 Aug. 1942; Guatemala, Dept. Huehuetenango, above San Ildefonso Ixtahuacán; 1,600–1,700 m; F (holo) = *Cladocolea oligantha* (Standl. & Steyerm.) Kuijt, 1974.

Struthanthus papillosus Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 43. 1944. *H. von Tuerckheim II.1240*; June 1906; Guatemala, Dept. Alta Verapaz, Cobán; 1,350 m; F (holo).

Struthanthus tenuifolius Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 155. 1944. *J. A. Steyermark 51538*; 29 Aug. 1942; Guatemala, Dept. Huehuetenango, Ciénaga de Lagartero, below Miramar; 300 m; F (holo).

LYTHRACEAE

Cuphea serpyllifolia H.B.K. var. *tachirensis* Steyerm., Fieldiana Bot. 28(2): 420. 1952. *J. A. Steyermark 57162*; 12 July 1944; Venezuela, Táchira, between Villapaez and Betania along Río Táchira; 2,130–2,285 m; F (holo).

MAGNOLIACEAE

Magnolia chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 443. 1967. *J. A. Steyermark 75840*; 20 June 1953; Venezuela, Bolívar, Apacara-tepui, Chimantá Massif; 2,200–2,300 m; VEN (holo).

Magnolia ptaritepuiana Steyerm., Fieldiana Bot. 28(1): 233. 1951. *J. A. Steyermark 59547*; 30 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 2,100–2,285 m; F (holo).

Magnolia roraimae Steyerm., Fieldiana Bot. 28(1): 234. 1951. *J. A. Steyermark 59000*; 30 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 2,155 m; F (holo).

MALPIGHIACEAE

Banisteria alternifolia Steyerm., Fieldiana Bot. 28(2): 280. 1952. *J. A. Steyermark 61914*; 7 Apr. 1945; Venezuela, Monagas, Cerro de la Cueva de Dona Anita; 1,100–1,200 m; F (holo).

Blepharandra cretacea (Gleason) Steyerm. var. *composita* Steyerm., Fieldiana Bot. 28(2): 281. 1952. *J. A. Steyermark 58191*; 1 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,700–1,980 m; F (holo) = *B. hypoleuca* (Benth.) Griseb., 1981.

Blepharandra ptariana Steyerm., Fieldiana Bot. 28(2): 282. 1952. *J. A. Steyermark 60310*; 18 Nov. 1944; Venezuela, Bolívar, Ptari-tepui 1,220 m; F (holo) = *B. hypoleuca* (Benth.) Griseb., 1978.

Burdachia duckei Steyerm., Fieldiana Bot. 28(2): 283. 1952. *A. Ducke 522*; 14 July 1937; Brazil, Manaus, Igarape de Cachoeira Grande; F (holo), MO (1157729).

Burdachia williamsii Steyerm., Fieldiana Bot. 28(2): 285. 1952. *Ll. Williams 14321*; 1942; Venezuela, T. F. Amazonas, Río Guainía, Maroa; 127 m; F (holo).

Byrsonima bolivarana Steyerm., Fieldiana Bot. 28(2): 287. 1952. *J. A. Steyermark 60272*; 15–17 Nov. 1944; Venezuela, Bolívar, between Sororopan-tepui and Ptari-tepui; 1,615 m; F (holo) = *B. chalcophylla* var. *carraoana* (Steyerm.) Anders., 1981.

Brysonima carraoana Steyerm., Fieldiana Bot. 28(2): 287. 1952. *J. A. Steyermark 60883*; 7 Dec. 1944; Venezuela, Bolívar, Carrao-tepui; 2,470–2,500 m; F (holo) = *B. chalcophylla* var. *carraoana* (Steyerm.) Anders., 1981.

Byrsonima leutzelburgii Steyerm., Fieldiana Bot. 28(2): 288. 1952, nom. nov.

Glandonia williamsii Steyerm., Fieldiana Bot. 28(2): 288. 1942. *Ll. Williams 14154*; 2 Feb. 1942; Venezuela, T.F. Amazonas, Yavita; 128 m; F (holo).

"*Heteropterys*" *quetepensis* Steyerm., Fieldiana Bot. 28(2): 292. 1952. *J. A. Steyermark 62880*; 23 May 1945; Venezuela, Sucre, E of Cumana, near Quetepe, between km 18–20; 30 m; F (holo). Note: *Heteropteris* is the correct (conserved) spelling.

Hiraea tepuiensis Steyerm., Fieldiana Bot. 28(2): 293. 1952. *A. S. Pinkus 90*; 28 Dec. 1939; Venezuela, Bolívar, vicinity Arabupu, Mt. Roraima; 1,500 m; F (holo).

Mascagnia excelsa Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 168. 1944. *J. A. Steyermark 39456*; 14 Apr. 1940; Guatemala, Dept. Izabal, Río Dulce; sea level; F (holo).

"*Tetrapterys*" *phylladenophora* Maguire & Steyerm., Mem. New York Bot. Gard. 9: 481. 1957. *J. A. Steyermark & J. J. Wurdack 426*; 10–15 Feb. 1948; Venezuela, Bolívar, Uaipán-tepui; NY (holo) = *Tetrapteris rhodoptero* Oliver, 1981. Note: *Tetrapteris* is the correct spelling.

"*Tetrapterys*" *pusilla* Steyerm., Fieldiana Bot. 28(2): 294. 1952. *J. A. Steyermark 59391*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

MALVACEAE

Abutilon orientale Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 173. 1944. *P. C. Standley 74420*; 15 Oct. 1940; Guatemala, Dept. Zacapa, along road between Agua Blanca & Cumbre de Chiquimula; 350–500 m; F (holo).

Abutilon pachecoanum Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 61. 1944. *P. C. Standley 83528*; Jan. 1941; Guatemala, Dept. Quezaltenango, near Las Nubes, S of San Martín Chile Verde; 2,250 m; F (holo).

Abutilon pseudogiganteum Steyerm., Fieldiana Bot. 28(2): 362. 1952. *J. A. Steyermark 61519*; 16 Mar. 1945; Venezuela, Anzoátegui, between San José & Cucuta; 600–700 m; F (holo).

Abutilon tridens Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 173. 1944. *J. A. Steyermark 43439*; 4 Feb. 1942; Guatemala, Dept. El Progreso, hills between Finca Piamonte & slopes SE, Sierra de las Minas; 2,400 m; F (holo).

Abutilon turumiquirense Steyerm., Fieldiana Bot. 28(2): 63. 1952. *J. A. Steyermark 62689*; 10 May 1945; Venezuela, Sucre, Cerro Turumiquire; 1,300–1,800 m; F (holo).

Malvastrum guatemalense Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 174. 1944. *P. C. Standley 78534*; 20–27 Nov. 1940; Guatemala, Dept. Santa Rosa, near Cuilapa; 900 m; F (holo).

Pavonia imatacensis Steyerm., Acta Bot. Venez. 3: 181. 1968. *J. A. Steyermark 88149*; 17 Dec. 1960; Venezuela, Bolívar, Sierra Imataca, Río Toro (Río Grande); 200–250 m; VEN (holo).

Pseudabutilon inornatum Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(1): 15. 1943. *P. C. Standley 61425*; Dec. 1938; Guatemala, Dept. Guatemala, near Amatitlán; 1,170 m; F (holo).

MARANTACEAE

Calathea acuminata Steyerm., Fieldiana Bot. 28(1): 161. 1951. *Ll. Williams 15532*; 24 May 1942; Venezuela, T.F. Amazonas, Alto Casiquiare, Capihuara; 120 m; F (holo).

Calathea coccinea Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 39. 1944. *J. A. Steyermark 79345*; Mar. 1940; Guatemala, Dept. San Marcos, above Finca El Porvenir, along Río Cabús, Volcán Tajumulco; 1,300–1,500 m; F (holo).

Calathea duidae Steyerm., Fieldiana Bot. 28(1): 162. 1951. *J. A. Steyermark 57888*; 23 Aug. 1944; Venezuela, T.F. Amazonas, SE base of Cerro Duida; 210 m; F (holo).

Calathea lasseriana Steyerm., Fieldiana Bot. 28(1): 163. 1951. *J. A. Steyermark 57920*; 23 Aug. 1944; Venezuela, T.F. Amazonas, SE base of Cerro Duida; 215 m; F (holo).

Ischnosiphon lasseriana Steyerm., Fieldiana Bot. 28(1): 164. 1951. *J. A. Steyermark 60557*; 15 Nov. 1944; Venezuela, Bolívar, below Santa Teresita de Kavanayen; F (holo).

Monotagma duidae Steyerm., Fieldiana Bot. 28(1): 164. 1951. *J. A. Steyermark 57807*; 22 Aug. 1944; Venezuela, T.F. Amazonas, SE base of Cerro Duida; 200 m; F (holo).

Monotagma yapacanensis Steyerm. & Bunting, Acta Bot. Venez. 8: 114. 1973. *J. A. Steyermark & G. Bunting 103062*; 3 May 1970; Venezuela, T.F. Amazonas, Cerro Yapacana; 125–400 m; VEN (holo).

Thymocarpus Nicolson, Steyerm. & Sivad., Brittonia 33: 22. 1981, Gen. nov.

Thymocarpus cannoides Nicolson, Steyerm. & Sivad., Brittonia 33: 24. 1981; *B. Maguire et al. 53608*; 5 Sep. 1962; Venezuela, Bolívar, SE end of Cerro Piton, Cordillera Epicara, alta Río Cuyuni; 40 m; MO (2892301), NY, US, VEN (holo).

MARCGRAVIACEAE

Marcgravia sororopaniana Steyerm., Fieldiana Bot. 28(2): 378. 1952. *J. A. Steyermark 60127*; 14 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,255 m; F (holo).

Ruyschia longistylis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 175. 1944. *J. A. Steyermark 49545*; 26 July 1942; Guatemala, Dept. Huehuetenango, Cafetal of Finca Soledad, Sierra de los Cuchumatanes; 1,150 m; F (holo) = *R. enervia* Lundell, 1961.

Souroubea guianensis Aublet var. *tomentella* Steyerm., Fieldiana Bot. 28(2): 378. 1952. *J. A. Steyermark 60652*; 27 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo).

Souroubea micrantha Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 62. 1944. *P. C. Standley 72793*; Apr.–May 1939, Guatemala, Dept. Izabal, near Puerto Barrios; sea level; F (holo) = *S. triandra* Lundell, 1961.

Souroubea puberula Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 175. 1944. *J. A. Steyermark 46862*; 2 June 1942; Guatemala, Dept. Suchitepéquez, Loma Grande, above Finca El Naranjo, Volcán de Santa Clara; 2,000 m; F (holo) = *S. exauriculata* Delpino, 1961.

MELASTOMATACEAE

Conostegia gleasoniana Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 22(5): 361. 1940. *P. C. Standley 70317*; 2 Apr. 1939; Guatemala, Dept. Alta Verapaz, Cocolá, NE of Carchá; 1,200 m; F (holo) = *C. hirtella* Cogn., 1963.

Conostegia volcanalis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 136. 1944. *P. C. Standley 68152*; 8 Mar. 1939; Guatemala, Dept. Quezaltenango, Chiquihuite; 1,410 m; F (holo).

Diolena calciphila Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 133. 1944. *A. F. Skutch 1811*; 2 Dec. 1934; Guatemala, Dept. Quiché, Zona Reina; 750 m; F (holo) = *Triolena calciphila* (Standl. & Steyerm.) Standl. & L. Williams, 1963.

Diolena roseiflora Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 134. 1944. *J. A. Steyermark 41819*; 24 Dec. 1941; Guatemala, Dept. Izabal, along Río Tamejá, Cerro San Gil; 50 m; first cited specimen, type not designated. = *Triolena roseiflora* (Standl. & Steyerm.) Standl. & L. Williams, 1963.

Diolena stenophylla Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 135. 1944. *J. A. Steyermark 48728*; 15–16 July 1942; Guatemala, Dept. Huehuetenango, between Maxbal and lake to the SE; 1,500 m; F (holo) = *Triolena stenophylla* (Standl. & Steyerm). Standl. & L. Williams, 1963.

Miconia echinoidea Standl. & Steyerm., Field. Must. Nat. Hist., Bot. Ser. 23(4): 180. 1944. *J. A. Steyermark 48831*; 15–16 July 1942; Guatemala, Dept. Huehuetenango, vicinity of Maxbal, Sierra de los Cuchumatanes; 1,500 m; F (holo).

Miconia tixixensis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 181. 1944. *J. A. Steyermark 31585*; 10 Nov. 1939; Guatemala, Dept. Chiquimula, Cerro Tixixí; 1,500 m; F (holo).

Monochaetum guatemalense Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 136. 1944. *J. A. Steyermark 48512*; 10 July 1942; Guatemala, Dept. Huehuetenango, vicinity of Quetzal; 2,300 m; F (holo) = *Heterocentron elegans* (Schlecht.) Kuntze, 1963.

Rhynchanthera medialis Standl. & Steyerm. Field. Mus. Nat. Hist., Bot. Ser. 23: 137. 1944. *J. A. Steyermark 36386*; 22 Feb. 1940; Guatemala, Dept. San Marcos, along Quebrada Suchiate, near SE portion of Volcán Tacaná; 2,000–3,000 m; F (holo).

Triolena izabalensis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 138. 1944. *C. L. Wilson 175*; 7 Feb. 1939; Guatemala, Dept. Izabal, near Río Lámpara; F (holo).

MELIACEAE

Guarea chirriactensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 167. 1944. *J. A. Steyermark 46355*; 10 May 1942; Guatemala, Dept. Alta Verapaz, along Route 5, between Chirreacté & Semococh; 500–900 m; F (holo) = *Trichilia chirriactensis* (Standl. & Steyerm.) Penn., 1981.

Trichilia privigna Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 167. 1944. *J. A. Steyermark 45827*; 21 Apr. 1942; Guatemala, Dept. Petén, along Río Santa Isabel, between mouth of Río Sebol and El Porvenir; 100 m; F (holo) = *T. breviflora* S. F. Blake & Standl., 1981.

"*Trichilia ptariana*" Steyerm., Fieldiana Bot. 28(2): 278. 1952. *J. A. Steyermark 59979*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo) = *Matayba oligantha* Sandw., 1981. Note: The *Trichilia* name was a homonym, non A. C. Smith, 1933.

Trichilia subsimplex Steyerm., Fieldiana Bot. 28(2): 279. 1952. *J. A. Steyermark 58061*; 28–29 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 260 m; F (holo), NY, US, VEN = *T. pallida* Sw., 1981.

MENDONCIACEAE

Mendoncia guatemalensis Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(5): 245. 1947. *J. A. Steyermark 49270*; 23 July 1942; Guatemala, Dept. Huehuetenango, between Ixcán & Río Ixcán; 150–200 m; F (holo).

Mendoncia mellobarretoana Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 17(5): 421. 1938. *H. L. Mello Barreto 226*; 1 Dec. 1934; Brazil, Suyo, Jardim Botanicão Mun. Belo Horizonte, Minas Gerais; F (holo).

MENISPERMACEAE

Hyperbaena salvadorensis Steyerm., Ceiba 4: 301. 1955. *J. M. Tucker 979*; 23 Feb. 1942; El Salvador, Dept. San Miguel, Volcán San Miguel, 0.8 km SW of buildings of hacienda of Max Haltmeyer; F (holo).

Hyperbaena vulcania Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(1): 8. 1943. *P. C. Standley 63878*; Jan. 1939; Guatemala, Dept. Escuintla, near Barranco Hondo, above Las Lajas; 1,200 m; F (holo).

MONIMIACEAE

Mollinedia glabricaulis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989.

Mollinedia neblinensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *N. T. Silva & U. Brazao 60678*; Brazil, Serra da Neblina, Rio Negro, Rio Cauaburi, Rio Maturacá, between Anta and Palmito camps; 600–1,300 m; MO (3291192), NY (holo).

Mollinedia ptariensis Steyerm., Fieldiana Bot. 28(1): 235. 1951; *J. A. Steyermark 60014*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Mollinedia roraimensis Steyerm., Fieldiana Bot. 28(1): 236. 1951. *J. A. Steyermark 59004*; 30 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 2,040–2,255 m; F (holo).

Siparuna manarae Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 453. 1966. *B. J. Manara 51*; 27 June 1964; Venezuela, Distr. Federal, Cerro Naiguitá, Quebrada Río Chiquito; VEN (holo) = *S. stellulata* Perkins var. *marnarae* (Steyerm.) Steyerm., 1978.

Siparuna rugosa Steyerm., Phytologia 9(6): 342. 1964. *M. Acosta Solis 7008*; 18 Jan. 1944; Ecuador, Prov. Pichincha, bojada de Lache e Condor Machay, Cordillera Occidental; 2,700–3,100 m; F (holo).

Siparuna verrucosa Steyerm., Phytologia 9(6): 343. 1964. *M. Acosta Solis 8233*; 19 June 1944; Ecuador, Prov. Imbabura, Urcusique, faldas occidental del Cotacachi; 3,300 m; F (holo).

MORACEAE

Ficus cabusana Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 22(4): 226. 1940. *J. A. Steyermark 37583*; 12 Mar. 1940; Guatemala, Dept. San Marcos, Finca El Porvenir, on Potrero Matasán, along Río Cabús, Volcán Tajumulco; 1,000 1,300 m; F (holo).

Pseudolmedia simiarum Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(4): 154. 1944. *J. A. Steyermark 48741*; 15–16 July 1942; Guatemala, Dept. Huehuetenango, Maxbal; 1,500 m; F (holo).

MYRICACEAE

Myrica rotundata Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 441. 1967. *J. A. Steyermark 75804*; 20 June 1953; Venezuela, Bolívar, Apacara-tepui, Chimantá Massif; 2,000–2,150 m; VEN (holo).

MYRSINACEAE

Ardisia apoda Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(5): 219. 1947. *J. A. Steyermark 41923*; 25 Dec. 1941; Guatemala, Dept. Izabal, Cerro San Gil; 300–900 m; F (holo).

Ardisia carlsonae Steyerm., Ceiba 4: 301. 1955. *M. C. Carlson 1744*; n.d.; Mexico, Chiapas, around Los Arcos, Los Lagos, 3 mi. NW of Rancho San José and 34 mi. SE of Comitán; 1,600 m; F (holo) = *Oerstedianthus carlsonae* (Steyerm.) Lundell, 1983.

Ardisia meridensis Steyerm., Fieldiana Bot. 28(3): 454. 1953. *J. A. Steyermark 56325*; 6 May 1944; Venezuela, Mérida, between Mucuchachi & Canagua; 1,065–1,820 m; F (holo).

Ardisia vatteri Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(5): 220. 1947. *J. A. Steyermark 48558*; 14 July 1942; Guatemala, Dept. Huehuetenango, Cerro Huitz, Cerro de los Cuchumatanes; 1,500–2,600 m; F (holo) = *Gentlea vatteri* (Standl. & Steyerm.) Lundell, 1964.

Conomorpha apiculata Steyerm., Fieldiana Bot. 28(3): 456. 1953. *J. A. Steyermark 57986*; 25–26 Aug.

1944; Venezuela, T.F. Amazonas, Cerro Duida; 305–1,095 m; F (holo).

Conomorpha densipapillata Steyerm., Fieldiana Bot. 28(3): 457. 1953. *J. A. Steyermark 56539*; 14 May 1944; Venezuela, Mérida, Páramo de Los Colorados, between El Molino & San Isidro Alto; 2,745–2,955 m; F (holo).

Conomorpha depressa Steyerm., Fieldiana Bot. 28(3): 458. 1953. *J. A. Steyermark 60898*; 7 Dec. 1944; Venezuela, Bolívar, Carrao-tepui; 2,470–2,500 m; F (holo).

Conomorpha frigidicola Steyerm., Fieldiana Bot. 28(3): 458. 1953. *J. A. Steyermark 56516*; 14 May 1944; Venezuela, Mérida, between El Molino & ridge above San Isidro Alto; 2,430–2,895 m; F (holo) = *Cybianthus frigidicola* (Steyerm.) Agost., 1972.

Conomorpha hieronymoides Steyerm., Fieldiana Bot. 28(3): 460. 1953. *J. A. Steyermark 55295*; 5 Feb. 1944; Venezuela, Lara, Las Sabanetas; 2,530 m; F (holo) = *Cybianthus laurifolius* (Mez) Agost., 1972.

Conomorpha jajiensis Steyerm., Fieldiana Bot. 28(3): 462. 1953. *J. A. Steyermark 55980*; 21 Apr. 1944; Venezuela, Mérida, above Jaji, Los Quebraditos; 2,590 m; F (holo).

Conomorpha larensis Steyerm., Fieldiana Bot. 28(3): 463. 1953. *J. A. Steyermark 55392*; 8 Feb. 1944; Venezuela, Lara, above Humocaro Baja, S of Las Sabanetas; 2,430–2,745 m; F (holo).

Conomorpha lepidota Gleason f. *acutata* Steyerm., Fieldiana Bot. 28(3): 465. 1953. *J. A. Steyermark 58265*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,025–1,200 m; F (holo) = *Cybianthus lepidotus* (Gleason) Agost., 1972.

Conomorpha leprosa Steyerm., Fieldiana Bot. 28(3): 465. 1953. *J. A. Steyermark 59136*; 2 Oct. 1944; Venezuela, Bolívar, S of Mt. Roraima, Gran Sabana; 1,065 m; F (holo).

Conomorpha liriensis Steyerm., Fieldiana Bot. 28(3): 466. 1953. *J. A. Steyermark 57456*; 18 July 1944; Venezuela, Táchira, Alto de Lirio; 1,890–2,285 m; F (holo).

Conomorpha ptariensis Steyerm., Fieldiana Bot. 28(3): 466. 1953. *J. A. Steyermark 59632*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo), MO (1621331).

Conomorpha roraimae Steyerm., Fieldiana Bot. 28(3): 468. 1953. *J. A. Steyermark 58759*; 27 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 2,255–2,620 m; F (holo) = *Cybianthus roraimae* (Steyerm.) Agost., 1972.

Conomorpha sessilianthera Steyerm., Fieldiana Bot. 28(3): 471. 1953. *J. A. Steyermark 57253*; 14 July 1944; Venezuela, Táchira, Quebrada de Palmar at foot of Páramo de Tamá; 2,500 m; F (holo).

Conomorpha sulcata Steyerm., Fieldiana Bot. 28(3): 473. 1953. *J. A. Steyermark 57435*; 17 July 1944; Venezuela, Táchira, above Betania below Páramo de Tamá; 2,530 m; F (holo).

Conomorpha tamana Steyerm., Fieldiana Bot. 28(3): 475. 1953. *J. A. Steyermark 57359*; 15 July 1944; Venezuela, Táchira, base of Páramo de Tamá; 2,500–2,895 m; F (holo).

Grammadenia ptariensis Steyerm., Fieldiana Bot. 28(3): 476. 1953. *J. A. Steyermark 59497*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo).

Rapanea minima Steyerm., Fieldiana Bot. 28(3): 477. 1953. *J. A. Steyermark 58848*; 27 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 2,620–2,740 m; F (holo).

OCHNACEAE

Adenanthe Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 10(4): 19. 1961, gen. nov.

Adenanthe bicarpellata Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 10(4): 19. 1961. *J. A. Steyermark & J. J. Wurdack 377*; 3 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 1,940 m; MO (2011680), NY (holo).

Adenanthe bicarpellata Maguire, Steyerm. & Wurd. var. *chimantensis* Steyerm., ined.?. *J. A. Steyermark et al. 128637*; 2–5 Feb. 1983; Venezuela; MO (iso—3231620).

Ouratea asisae Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *J. Hoyos & G. Morillo 90*; 7 May 1973; Venezuela, T.F. Amazonas, Serranía Parú, Cerro Asisa (La Momia); 1,210 m; VEN (holo).

Ouratea ayacuchae Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *O. Huber & J. Cerda 1447*; 16 Jan. 1978; Venezuela, T.F. Amazonas, Dept. Atures, Puerto Ayacucho; 90 m; VEN (holo).

Ouratea brevicalyx Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *R. Cowan & J. J. Wurdack 31462*; 15 Feb. 1951; Venezuela, T.F. Amazonas, base of Cerro Parú, Serranía Parú; 100 m; NY (holo).

Ouratea brevipedicellata Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 41909*; 15 Oct. 1957; Venezuela, T.F. Amazonas, Río Guainía between Maroa and Guzman Blanco; 130 m; NY (holo).

Ouratea croizatii Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *L. Croizat 624*; 15 Sep. 1951; Venezuela, T.F. Amazonas, Raudal Bobadilla, alto Orinoco; NY (holo).

Ouratea culmenicola Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *J. A. Steyermark et al. 117393*; 23–24 May 1978; Venezuela, Cerro Guaiquinima, 1 km Río del Salto Szczerbanari; 730–750 m; MO (holo), VEN.

Ouratea deminuta Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *O. Huber 2504*; 23 Aug. 1978; Venezuela, T.F. Amazonas, Dept. Atabapo, Sabana de Minicio; 90 m; VEN (holo).

Ouratea discophora Ducke subsp. *pervenulosa* Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 36657*; 27 Nov. 1953; Venezuela, 50 km above mouth of Pacimoni; 120 m; NY (holo).

Ouratea duidae Steyerm., Fieldiana Bot. 28(2): 369. 1952. *J. A. Steyermark 58284*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,025–1,200 m; F (holo), NY.

Ouratea evoluta Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 29253*; 17 Oct. 1950; Venezuela, T.F. Amazonas, 15 km above San Fernando de Atabapo; 100 m; NY (holo).

Ouratea fasciculata Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *Forest Dept. Record No. 7227* (*Field No. G251*); 28 Sep. 1952; Guyana, 6 mi. E of Onoro Creek; NY (holo).

Ouratea gillyana (Dwyer) Sandw. & Maguire subsp. *pachypoda* Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire & D. B. Fanshawe 32629*; 16 Nov. 1951; Guyana, Sagaraimadoi Savanna, upper Mazaruni River, Pakaraima Mountains; NY (holo).

Ouratea guaiquinimae Maguire & Steyerm., ined. mss. = *O. guaiquinimensis* Sastre, 1988.

Ouratea huberi Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *O. Huber 1904*; 30 May 1978; Venezuela, T.F. Amazonas, Dept. Atabapo, Río Ventuari; 98 m; VEN (holo).

Ouratea inconformis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *F. Breteler 4832*; 25 Nov. 1965; Venezuela, T.F. Amazonas, Sipapo River near confluence with Orinoco River; 90 m; NY (holo), VEN.

Ouratea longistyla Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *O. Huber & E. Medina 5763*; 6 Feb. 1981; Venezuela, T.F. Amazonas, Dept. Río Negro, Río Siapo; 125 m; NY (holo), VEN.

Ouratea macurucoensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *P. E. Berry 2152*; 25 Mar. 1975; Venezuela, T.F. Amazonas, Piedra Blanca, 1 km Río arriba de Macuruco; 130 m; VEN (holo).

Ouratea marahuacensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *J. A. Steyermark & B. K. Holst 130907*; 1 Mar. 1985; Venezuela, T.F. Amazonas, Cerro Marahuaca, along tributary of Caño Negro; 1,140–1,150 m; MO (holo), NY, VEN.

Ouratea medinae Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *E. Medina 534*; Feb. 1971; Venezuela, T.F. Amazonas, Playa Tigre, Río Atabapo, San Fernando de Atabapo; VEN (holo).

Ouratea oligantha Maguire & Steyerm., ined. mss. = *O. soderstromii* Sastre, 1988.

Ouratea ornata Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire & L. Politi 27485*; 1–3 Dec. 1948; Venezuela, T.F. Amazonas, Cerro Sipapo (Paraque); 605–910 m; NY (holo).

Ouratea papillata Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *J. A. Steyermark & G. S. Bunting 103271*; 7 May 1970; Venezuela, T.F. Amazonas, along Río Yatua, base of Cerro Yapacana; 125 m; NY, VEN (holo).

Ouratea paruensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *R. Cowan & J. J. Wurdack 31104*; 31 Jan. 1951; Venezuela, T.F. Amazonas, Cerro Parú; 2,000 m; NY (holo).

Ouratea propinqua Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *J. A. Steyermark et al. 109447*; 24 Feb.–7 Mar. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,800 m; VEN (holo).

Ouratea psammophila Maguire & Steyerm., ined. mss. = *O. steyermarkii* Sastre, 1988.

Ouratea pseudotatei Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *A. S. Pinkus 277*; Jan. 1939; Guyana, Arabaru River (Kako tributary), upper Mazaruni drainage; NY (holo).

Ouratea ptaritepuiensis Steyerm., Fieldiana Bot. 28(2): 370. 1952. *J. A. Steyermark 59642*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo).

Ouratea pumila Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *O. Huber & S. S. Tillett 5481*; 22 July 1980; Venezuela, T.F. Amazonas, Dept. Atabapo, 5 mi. S of Laguna Yagua; 100 m; VEN (holo).

Ouratea pumila Maguire & Steyerm. var. *heterodoxa* Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *O. Huber & S. S. Tillett 5536*; 27 July 1980; Venezuela, T.F. Amazonas, Dept. Azures, 2 km N of Río Guayapo Medio; VEN (holo).

Ouratea ramosissima Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *F. Cardona 2204*; Oct. 1947; Venezuela, Bolívar, Cerro de Acopán (Macizo de Chimantá); 900 m; NY, VEN (holo).

Ouratea rotundipetala Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 30766*; 6 Jan. 1951; Venezuela, T.F. Amazonas, E-W Caño, N of Cerro Yapacana; 130 m; NY (holo).

Ouratea sipapoensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire & L. Politi 27631*; 12 Dec. 1948; Venezuela, T.F. Amazonas, Cerro Sipapo; 1,700 m; NY (holo).

Ouratea subamplexicaulis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *E. Foldats 2784*; 1 Jan. 1957; Venezuela, Bolívar, 105 km de El Dorado hacia Santa Elena; NY (holo).

Ouratea venezuelensis Steyerm., Fieldiana Bot. 28(2): 370. 1952. *Ll. Williams 14152*; 2 Feb. 1942; Venezuela, T.F. Amazonas, del Caño Temi, Yavita; 128 m; F (holo).

Ouratea wurdackiana Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *J. J. Wurdack & L. S. Adderley 42719*; 1 June 1959; Venezuela, T.F. Amazonas, Río Orinoco just above mouth of Río Atabapo; 125 m; NY (holo).

Ouratea yapacanae Maguire & Steyerm., ined. mss. = *O. yapacanae* Sastre, 1988.

Perissocarpa Steyerm. & Maguire, Ann. Missouri Bot. Gard. 71: 319. 1984, gen. nov.

Perissocarpa steyermarkii (Maguire) Steyerm. & Maguire subsp. *tachirensis* Steyerm. & Maguire, Ann. Missouri Bot. Gard. 71: 320. 1984. *J. A. Steyermark & B. Manara 125174*; 21 June 1981; Venezuela, Táchira, along Río San Buena, area of Presa Las Cuevas, ca. 10 km E of La Fundación; 550–600 m; VEN (holo).

Perissocarpa umbellifera Steyerm. & Maguire, Ann. Missouri Bot. Gard. 71: 320. 1984. *B. Maguire et al. 29529*; 18 Nov. 1950; Venezuela, T.F. Amazonas, Cerro Duida, Río Cunucunuma; 1,400 m; NY, VEN (holo).

Poecilandra pumila Steyerm., Fieldiana Bot. 28(2): 371. 1952. *J. A. Steyermark 59342*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

Sauvagesia L. sect. *Spatulatae* Steyerm., Fieldiana Bot. 28(2): 376. 1952, sect. nov.

Sauvagesia duidae Steyerm., Fieldiana Bot. 28(2): 372. 1952. *J. A. Steyermark 58021*; 26 Aug. 1944; Venezuela, T.F. Amazonas, near Caño Negro; 1,400 m; F (holo).

Sauvagesia guianensis (Eichl.) Sastre subsp. *aracamuniensis* Steyerm., Ann. Missouri Bot. Gard.: in press. 1989. *R. L. Liesner & F. Delascio 22075*; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp; 1,550 m; MO (holo), VEN.

Sauvagesia guianensis (Eichl.) Sastre subsp. *guaiquinimensis* Steyerm., Ann. Missouri Bot. Gard. 74: 101. 1987. *J. A. Steyermark et al. 117498*; Venezuela, T.F. Amazonas, Cerro Guaiquinima; 1,540 m; MO (holo), VEN.

Sauvagesia guianensis (Eichl.) Sastre subsp. *Sipapoensis* Steyerm., Ann. Missouri Bot. Gard. 74: 101. 1987. *J. A. Steyermark et al. 124530*; Venezuela, T.F. Amazonas, Serranía Sipapo; 1,500 m; MO (holo), VEN.

Sauvagesia imthurniana (Oliver) Dwyer subsp. *chimantensis* Maguire, Steyerm. & Wurd., Mem. New York Bot. Gard. 10(4): 17. 1961. *J. J. Wurdack 34201*; 26 Jan. 1953; Venezuela, Bolívar, Churi-tepui (Murutepui); 2,250–2,300 m; F, NY (holo).

Sauvagesia longipes Steyerm., Fieldiana Bot. 28(2): 374. 1952. *J. A. Steyermark 60215*; 15 Nov. 1944; Venezuela, Bolívar, Salto de Iwaracaru-meru, Sororopan-tepui; 1,615 m; F (holo), MO (1313407).

Sauvagesia marahuacensis Steyerm., Ann. Missouri Bot. Gard. 74: 98. 1987. *R. L. Liesner 17677a*; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca, Río Yameduaka arriba; MO (holo), VEN.

Sauvagesia marahuacensis Steyerm. subsp. *neblinensis* Steyerm., Ann. Missouri Bot. Gard.: in press. 1987. *R. L. Liesner 16809*; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro de la Neblina, Camp IV; 780 m; MO (holo), VEN.

Sauvagesia miniata Steyerm., Fieldiana Bot. 28(2): 376. 1952. *J. A. Steyermark 58467*; 8 Sep. 1944; Venezuela, T.F. Amazonas, vicinity of Sanariapo; 100 m; F (holo), MO (324780).

Tyleria breweriana Steyerm., Ann. Missouri Bot. Gard. 71: 322. 1984. *J. A. Steyermark et al. 124326*; 14 Feb. 1981; Venezuela, Bolívar, Dept. Sucre, Meseta de Jaua; 2,020 m; VEN (holo).

Tyleria phelpsiana Maguire & Steyerm., Mem. New York Bot. Gard. 23: 866. 1972. *J. A. Steyermark 98049*; 22–27 Mar. 1967; Venezuela, Bolívar, Meseta de Jaua, Cerro Jaua; 1,922–2,100 m; NY (holo), VEN.

OLACACEAE

Dulacia redmondii Steyerm., Phytologia 38(3): 217. 1978. *J. A. Steyermark & P. Redmond 112829*; 28 Dec. 1976; Venezuela, T.F. Amazonas, Canaripo, lado sur del Río Ventuari; 125 m; US, VEN (holo).

Heisteria olivae Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 453. 1966. *J. A. Steyermark 92077*; 15–19 Nov. 1963; Venezuela, Distr. Federal, Cerro Naiguata; 1,000–1,300 m; NY, S, US, VEN (holo) = *H. latifolia* Standl., 1984.

Liriosma tepuiensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 328. 1976. *J. A. Steyermark et al. 109041*; 13 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Sarisariñama; 1,320 m; F, K, L, NY, VEN (holo) = *Dulacia tepuiensis* (Steyerm.) Sleumer & Steyerm., 1984.

Schoepfia clarkii Steyerm., Ann. Missouri Bot. Gard. 75: 1061. 1988. *H. L. Clark 8111*; 16 Aug. 1987; Venezuela, T.F. Amazonas, 10.8 km NE of San Carlos on Solano road; 119 m; MO (holo).

Schoepfia tepuiensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 331. 1976. *J. A. Steyermark 93413*; 5 May 1964; Venezuela, Bolívar, Auyan-tepuy; 1,850 m; K, NY, P, S, U, US, VEN (holo).

OLEACEAE

Fraxinus bicolor Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 73. 1944. *P. C. Standley 80408*; Dec. 1940; Guatemala, Dept. Guatemala, near Fiscal; 1,100 m; F (holo).

Fraxinus cavekiana Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 74. 1944. *A. F. Skutch 1660*; Nov. 1934; Guatemala, Dept. Quiché, Nebaj; 1,860 m; F (holo).

Fraxinus vellerea Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 74. 1944. *P. C. Standley 76162*; Oct.–Nov. 1940; Guatemala, Dept. Jutiapa, near Jutiapa; 850 m; F (holo).

Linociera avilensis Steyerm., Brittonia 30: 45. 1978. *E. Delgado 233*; 9 May 1939; Venezuela, Distr. Federal, Cerro Avila; VEN (holo).

Menodora coulteri A. Gray var. *minima* Steyerm., Ann. Missouri Bot. Gard. 19: 121. 1932. *J. E. Kirkwood 20*; June 1908; Mexico, Zacatecas, Cedros, near Arroyos; F, MO (holo).

Menodora decemfida (Gill.) A. Gray var. *longifolia* Steyerm., Ann. Missouri Bot. Gard. 19: 143. 1932. *E. Palmer 429*; Apr., Aug. 1896; Mexico, Durango, Santiago, Papasquiara; MO (holo).

Menodora helianthemoides Humb. & Bonpl. var. *engelmannii* Steyerm., Ann. Missouri Bot. Gard. 19: 119. 1932. *J. Gregg 44*; 7 May 1948; Mexico, Coahuilla, near Saltillo; GH, MO (holo).

Menodora helianthemoides Humb. & Bonpl. var. *humilis* Steyerm., Ann. Missouri Bot. Gard. 19: 118. 1932. *C. C. Parry & E. Palmer 571pp*; 1878; Mexico, San Luis Potosí, region of San Luis Potosí; 1,849 2,439 m; F, G, MO (holo).

Menodora helianthemoides Humb. & Bonpl. var. *magniflora* Steyerm., Ann. Missouri Bot. Gard. 19: 118. 1932. *C. C. Parry & E. Palmer 570pp*; 1878; Mexico, San Luis Potosí, region of San Luis Potosí; 1,829–2,439 m; F, GH, MO (holo).

Menodora heterophylla Moric. ex DC. var. *australis* Steyerm., Ann. Missouri Bot. Gard. 19: 127. 1932. *Pegler 950*; Aug. 1903; South Africa, Transvaal, near Rustenburg; 1,220 m; B (holo).

Menodora intricata Brandg. var. *purpusii* Steyerm., Ann. Missouri Bot. Gard. 19: 150. 1932. *C. A. Purpus 1318*; June 1905; Mexico, Puebla, Tehuacan; F, GH, MO (holo), NY.

Menodora pinnatisecta Steyerm., Ann. Missouri Bot. Gard. 19: 133. 1932. *Jörgensen 2643*; 9 Nov. 1917; Argentina, Terr. del Chaco, Las Palmas; GH (holo).

Menodora scabra Engelm. ex A. Gray var. *longituba* Steyerm., Ann. Missouri Bot. Gard. 19: 141. 1932. *Smart 213*; 5 May 1867; U.S.A., Arizona, Massatzal Mountains; GH (holo).

Menodora scabra Engelm. ex A. Gray var. *ramosissima* Steyerm., Ann. Missouri Bot. Gard. 19: 139. 1932. *E. J. Palmer 31083*; 19 June 1926; U.S.A., Texas, El Paso Co., near El Paso; MO (holo).

Menodora spinescens A. Gray var. *mohavensis* Steyerm., Ann. Missouri Bot. Gard. 19: 155. 1932. *S. B. Parish 9795*; 23 Apr. 1915; U.S.A., California, San Bernardino Co., Mojave Desert, 14 mi. NE of Barstow; CAS (holo).

ONAGRACEAE

Fuchsia adpressipilis Steyerm., Fieldiana Bot. 28(2): 438. 1952. *J. A. Steyermark 55381*; 8 Feb. 1944; Venezuela, Lara, between Santo Domingo and Los Quebraditos, S of Las Sabanetas; 2,430–2,475 m; F (holo).

Fuchsia meridensis Steyerm., Fieldiana Bot. 28(2): 439. 1952. *J. A. Steyermark 56162*; 27 Apr. 1944; Venezuela, Mérida, between La Azulita and La Trampa; 1,280–2,225 m; F (holo).

Fuchsia verrucosa Hartw. var. *tamaensis* Steyerm., Fieldiana Bot. 28(2): 440. 1952. *J. A. Steyermark 57175*; 13 July 1944; Venezuela, Táchira, base of Páramo de Tamá, between Betania and Tamá; 2,430 m; F (holo).

"Ludvigia" alternifolia L. var. *pubescens* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 772. 1938. *E. J. Palmer & J. A. Steyermark 41450*; 11 July 1933; U.S.A., Missouri, 4 mi. W of Charleston; GH, MO (holo) = *Ludwigia alternifolia* L. var. *alternifolia*, 1963.

Oenothera pilosella Raf. f. *laevigata* Palmer & Steyerm., Brittonia 10: 116. 1958. *J. A. Steyermark 78703*; 25 June 1955; U.S.A., Missouri, Howell Co., 4 mi. S of West Plains; F (holo) = *O. pilosella* Raf. var. *pilosella*, 1981.

ORCHIDACEAE

Scaphyglottis michelangeliorum Carnevali & Steyerm., Phytologia 55(5): 289. 1984. *J. A. Steyermark 129650*; 13–14 Oct. 1983; Venezuela, T.F. Amazonas, faldas del Cerro Marahuaca; 1,550 m; VEN (holo).

OXALIDACEAE

Oxalis calcicola Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(3): 118. 1944. *J. A. Steyermark 50258*; 8 Aug. 1942; Guatemala, Dept. Huehuetenango, vicinity Chemal, Sierra de los Cuchumatanes; 3,700 m; F (holo).

Oxalis minarum Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 58. 1944. *J. A. Steyermark 29718*; Oct. 1939; Guatemala, Dept. Zacapa, Sierra de las Minas, Finca Alejandría; 1,000–1,500 m; F (holo).

PASSIFLORACEAE

Dilkea magnifica Steyerm., Acta Bot. Venez. 3: 186. 1968. *J. A. Steyermark 87606*; 18 Nov. 1960; Venezuela, Terr. Delta Amacuro, Cerro La Paloma, Sierra Imataca; 100–200 m; NY (holo).

Passiflora bomareifolia Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 455. 1967. *J. A. Steyermark & J. J. Wurdack 1370*; 11 Mar. 1955; Venezuela, Bolívar, Amuri-tepui, Chimantá Massif; 850–1,275 m; MO (2011386), VEN (holo).

Passiflora nuriensis Steyerm., Acta Bot. Venez. 3: 188. 1968. *J. A. Steyermark 88425*; 14 Jan. 1961; Venezuela, Bolívar, Altiplanicie de Nuria, Agua Linda; 400 m; MO (1803670, 180670), NY (holo).

PIPERACEAE

Peperomia acuminata Ruíz & Pavón f. *rubra* Steyerm., Fl. Venez. 2(2): 33. 1984. *L. Ruíz Terán 6461*; 29 Sep. 1971; Venezuela, Mérida, Dept. Rangel, entre Canada del Padre y El Baho, unos 10 km al E de la Sierra Nevada de Santo Domingo; 2,300–3,340 m; MERF, VEN (holo).

Peperomia aristeguietae Steyerm., Acta Bot. Venez. 6: 83. 1971. *J. A. Steyermark 103733*; 17 Aug. 1970;

Venezuela, Distr. Federal, S of Carvao, Río Aguas Calientes; 50–100 m; VEN (holo).

Peperomia aroensis Steyerm., Fl. Venez. 2(1): 50. 1984. *L. Aristeguieta & F. Pannier 1924*; 6–7 July 1953; Venezuela, Yaracuy, Sierra de Aroa; VEN (holo).

Peperomia atabapoensis Steyerm., Fl. Venez. 2(1): 52. 1984. *S. S. Tillett et al. 743-230*; 23–26 Mar. 1974; Venezuela, T.F. Amazonas, Dept. Atabapo, Caño Pavon, margen derecha del Río Orinoco, arriba de San Fernando de Atabapo; 130 m; VEN (holo).

Peperomia berryi Steyerm., Fl. Venez. 2(1): 53. 1984. *P. E. Berry et al. 3923*; 19 June 1982; Venezuela, Falcón, Urapagual, 'Los Haitoncitos,' ca. 2 km SE de Curimagua, ladera sur de la Sierra de San Luis; 1,200–1,300 m; VEN (holo).

Peperomia boomii Steyerm., Brittonia 38: 220. 1986. *B. Boom & M. Grillo 6417*; 26 Oct. 1985; Venezuela, Bolívar, Distr. Cedeño, vicinity of Panare, village of Corozal, 6 km from Maniapure toward Caicara; 200 m; MYR, NY (holo), VEN.

Piper veraguense C. DC. var. *venezuelense* Steyerm., Fl. Venez. 2(2): 590. 1984. *F. Breteler 4082*; 11 Aug. 1964; Venezuela, Trujillo, 16 km de Bucono, a lo largo de la carretera a Biscucuy; 1,850 m; MER, VEN (holo).

Piper vitaceum Yuncker var. *venezuelense* Steyerm., Fl. Venez. 2(2): 594. 1984. *J. A. Steyermark & S. Nilsson 176*; 15–17 Apr. 1960; Venezuela, Bolívar, la Fila de La Danta, entre Luepa y Cerro Venamo; 1,200 m; VEN (holo).

Piper wingfieldii Steyerm., Fl. Venez. 2(2): 595. 1984. *R. L. Liesner et al. 8211*; 27 June 1979; Venezuela, Falcón, area disputada entre el Edo. Lara y el Edo. Falcón, Cerro Cerron; 1,800–2,000 m; VEN (holo).

Sarcorhachis venezuelana Steyerm., Pittieria 3: 33. 1971. *J. A. & C. Steyermark 95152*; 27–28 Mar. 1966; Venezuela, Carabobo, del Río San Gian, al Sur de Borburata, arriba de la planta electrica, entre Los Tanques y La Toma; 750 m; US, VEN (holo).

POACEAE

Muhlenbergia brachyphylla Bush f. *aristata* Palmer & Steyerm., Brittonia 10: 110. 1958. *J. A. Steyermark 82921*; 7 Oct. 1956; U.S.A., Missouri, Pike Co., vicinity of Stillhouse Cave, along City Fork of Spencer Creek; F (holo), US.

POLEMONIACEAE

Phlox divaricata L. var. *laphamii* Woodson f. *candida* Palmer & Steyerm., Rhodora 57: 316. 1955. *E. J. Palmer 55411*; 30 Apr. 1953; U.S.A., Missouri, Barton Co., 1 mi. W of Nashville; Palmer Herbarium (holo), F.

POLYGALACEAE

Polygala appressa Benth. var. *kavanayena* Steyerm., Fieldiana Bot. 28(2): 298. 1952. *J. A. Steyermark 59359*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

Polygala blakeana Steyerm., Fieldiana Bot. 28(2): 298. 1952. *J. A. Steyermark 59065*; 10 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,065–1,200 m; F (holo).

Polygala rimulicola Steyerm., Ann. Missouri Bot. Gard. 19: 390. 1932. *J. A. Moore & J. A. Steyermark 3515*; 20 July 1931; U.S.A., Texas, Culberson Co., Smith Canyon, Guadalupe Mts.; 1,900 m; GH (holo), MO (1011635).

Polygala sanariapoana Steyerm., Fieldiana Bot. 28(2): 301. 1952. *J. A. Steyermark 59452*; 8 Sep. 1944; Venezuela, T.F. Amazonas, Sanariapo; 100 m; F (holo).

Polygala santanderensis Killip & Steyerm., Fieldiana Bot. 28(2): 301. 1952. *Killip & Smith 16585*; 5–6 Jan. 1927; Colombia, Dept. Santander, Río Surata valley; 2,000–2,300 m; F, US (holo).

PORTULACACEAE

Montia calcicola Standl. & Steyerm., Field. Mus. Nat. Hist., Bot. Ser. 23(2): 48. 1944. *J. A. Steyermark 50308*; 8 Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Chemal; 3,700–3,800 m; F (holo).

Portulaca insignis Steyerm., Ann. Missouri Bot. Gard. 75: 1058. 1988. *G. Morillo & G. Carnevali 8260*; 26 Feb. 1980; Venezuela, Bolívar, carretera Ciudad

Bolívar–Maripa, 100 km W of Ciudad Bolívar; 100–200 m; VEN (holo).

Portulaca pygmaea Steyerm., Ann. Missouri Bot. Gard. 75: 1058. 1988. *B. Maguire et al. 36188*; 12 Nov. 1953; Venezuela, T.F. Amazonas, 1 km E of Hotel Amazonas, Puerto Ayacucho; 100 m; NY (holo).

PRIMULACEAE

Lysimachia quadriflora Sims f. *albescens* Steyerm., Rhodora 54: 257. 1952. *J. A. Steyermark 68397*; 4 July 1949; U.S.A., Missouri, Carter Co., along route 60 along spring branch tributary to right fork of Carter Creek, 6.7 mi. NE of Van Buren; F (holo).

PROTEACEAE

Euplassa chimantensis Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 77. 1963. *J. A. Steyermark & J. J. Wurdack 1103*; 23 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 1,955–2,090 m; VEN (holo), F, NY.

Euplassa venezuelana Steyerm., Fieldiana Bot. 28(1): 217. 1951. *J. A. Steyermark 60824*; 30 Nov. 1944; Venezuela, Bolívar, NW of Santa Teresita de Kavanayen, along Río Karuai; 1,220 m; F (holo).

Panopsis cuaoensis Steyerm., Ann. Missouri Bot. Gard. 74: 612. 1987. *B. Maguire & L. Politi 28409*; 17 Jan. 1949; Venezuela, T.F. Amazonas, Río Cuao, Río Orinoco; NY (holo).

Panopsis ornatinervia Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 79. 1963. *J. A. Steyermark & J. J. Wurdack 1036*; 21 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,030–2,150 m; F, NY, VEN (holo).

Panopsis parimensis Steyerm., Ann. Missouri Bot. Gard. 74: 612. 1987. *O. Huber 6136*; 12 June 1981; Venezuela, T.F. Amazonas, Dept. Atabapo, Sierra Parima, 25 km NNE de Parima 'B,' cabeceras del Río Ocamo; MO (3295700), NY, VEN (holo).

Panopsis perijensis Steyerm., ined.? *J. A. Steyermark et al. 105677*; 27 Mar. 1972; Venezuela, Zulia, Sierra de Perija, Suroeste de Pishikakao e Iría hacia la Misión de Sucurpo; 1,500–1,800 m; MO (iso—2680841).

Panopsis ptariana Steyerm., Fieldiana Bot. 28(1): 218. 1951. *J. A. Steyermark 59677*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo).

Panopsis tepuiana Steyerm., Fieldiana Bot. 28(1): 219. 1951. *J. A. Steyermark 59988*; 10–11 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,585–1,600 m; F (holo).

Roupala chimantensis Steyerm., Bol. Soc. Venez. Ci. Nat. 25: 81. 1963. *J. A. Steyermark & J. J. Wurdack 1105*; 23 Feb. 1955; Venezuela, Bolívar, Chimantá Massif; 2,090 m; VEN (holo), F, MO (2011335), NY.

Roupala griotii Steyerm., Phytologia 44(5): 321. 1979. *J. A. Steyermark et al. 117920*; 22 Feb. 1979; Venezuela, T.F. Amazonas, vecindades del Río Coro-Coro y del aeropuerto de Yutaje; VEN (holo).

Roupala minima Steyerm., Fieldiana Bot. 28(1): 220. 1951. *J. A. Steyermark 60234*; 15–17 Nov. 1944; Venezuela, Bolívar, between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo).

Roupala obovata H.B.K. var. *ecuadorensis* Steyerm., Phytologia 9(6): 342. 1964. *J. A. Steyermark 54825*; 20 Oct. 1943; Ecuador, Prov. Loja, along Río Cachiyacu at Tambo Cachiyacu; 2,000 m; F (holo).

Roupala paruensis Steyerm., Ann. Missouri Bot. Gard. 74: 613. 1987. *R. S. Cowan & J. J. Wurdack 31378*; 10 Feb. 1951; Venezuela, T.F. Amazonas, Cerro Parú, S-SE to edge descent to tributary of Caño Asisa, Río Ventuari; 2,000 m; NY (holo).

Roupala sororopana Steyerm., Fieldiana Bot. 28(1): 220. 1951. *J. A. Steyermark 60089*; 13 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,225–2,255 m; F (holo).

QUIINIACEAE

Froesia venezuelensis Steyerm. & Bunting, Brittonia 27: 175. 1975. *J. A. Steyermark & G. S. Bunting 105237*; 12 Oct. 1971; Venezuela, Yaracuy, entre Nirgua y Las Marias; 1,000–1,200 m; NY, US, VEN (holo).

RANUNCULACEAE

Anemone virginiana L. f. *plena* Palmer & Steyerm., Brittonia 10: 113. 1958. *G. E. Moore s.n.*; 1956; U.S.A., Missouri, St. Louis Co., Rockwoods Reservation; F (holo).

Clematis caleoides Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 52. 1944. *P. C. Standley 58732*; Dec. 1938; Guatemala, Dept. Chimaltenango, Cerro Tecpán, region of Santa Elena; 2,700 m; F (holo).

Clematis versicolor Small ex Rydb. f. *pubescens* Steyerm., Rhodora 40: 71. 1938. *Brinkley 268*; 24 July 1937; U.S.A., Arkansas, Sevier Co., Boggy Springs; F (holo).

Ranunculus nubigenus H.B.K. f. *subintegrus* Steyerm., Fieldiana Bot. 28(1): 232. 1951. *J. A. Steyermark 57481*; 21 July 1944; Venezuela, Mérida, above Los Apartaderos, above Laguna Mucubaji towards Laguna Negra; 3,625–3,655 m; F (holo) = *R. flagelliformis* Smith, 1971.

Thalictrum johnstonii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 229. 1940. *J. R. Johnston 1643*; 20 June 1940; Guatemala, Dept. Totonicapán, Desconsuelo; F (holo).

Thalictrum standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 229. 1940. *J. A. Steyermark 36258*; 20 Feb. 1940; Guatemala, Dept. San Marcos, Río Vega, near San Rafael and Guatemala–Mexican boundary Volcán Tacaná; 2,500–3,000 m; F (holo).

RAPATEACEAE

Kunhardtia radiata Maguire & Steyerm., Acta Amazonica 9(2): 267. 1979. *J. A. Steyermark & O. Huber 113851*; 4 May 1977; Venezuela, T.F. Amazonas, 35 km S of Puerto Ayacucho at Tobogán; 85 m; NY (holo), VEN.

Rapatea aracamuniana Steyerm., Ann. Missouri Bot. Gard.: in press. 1989. *R. L. Liesner & F. Delascio 22197*; 20 Oct. 1987; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni; 600 m; MO (holo), VEN.

Rapatea chimantensis Steyerm., Ann. Missouri Bot. Gard. 75: 313. 1988. *J. A. Steyermark 75584*; 24 May 1953; Venezuela, Bolívar, Chimantá Massif, lower southwestern slopes of Chimantá-tepui; 1,000 m; MO, NY, VEN (holo).

Stegolepis albiflora Steyerm., Ann. Missouri Bot. Gard. 74: 609–658. 1987. *J. A. Steyermark et al. 108873*; 10 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Sarisariâma, NE part; 1,410 m; VEN (holo), NY.

Stegolepis allenii Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 325. 1940. *P. H. Allen 2153*; 23 June

1940; Panama, Prov. Coclé, hills N of El Valle de Anton; 1,000 m; F (holo), MO (1227389) = *Epidryos allenii* (Steyerm.) Maguire, 1962.

Stegolepis gleasoniana Steyerm., Fieldiana Bot. 28(1): 130. 1951. *J. A. Steyermark 58040*; 26 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,095–1,520 m; F (holo).

Stegolepis huberi Steyerm., Ann. Missouri Bot. Gard. 74: 610. 1987. *O. Huber 9467*; 28 Apr. 1984; Venezuela, Bolívar, Kukenán-tepui; 2,500 m; MO, VEN (holo).

Stegolepis humilis Steyerm., Ann. Missouri Bot. Gard. 74: 611. 1987. *J. A. Steyermark et al. 132006*; 22–24 May 1986; Venezuela, Bolívar, Camarcaibari-tepui, SW-facing shoulder; 1,825 m; MO (holo—3514022, 3393686), VEN.

Stegolepis maguireana Steyerm., Ann. Missouri Bot. Gard. 71: 300. 1984. *J. A. Steyermark et al. 129962*; 14 Feb. 1984; Venezuela, Bolívar, Chimantá Massif, Acopan-tepui; 1,950 m; VEN (holo), NY.

Stegolepis minor Steyerm., Ann. Missouri Bot. Gard. 75: 315. 1988. *J. A. Steyermark 89577*; 28 Aug. 1961; Venezuela, Bolívar, Sierra de Lema, cabeceras del Río Chicanán; NY, VEN (holo).

Stegolepis parvipetala Steyerm., Fieldiana Bot. 28(1): 133. 1951. *J. A. Steyermark 59514*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo).

Stegolepis ptaritepuiensis Steyerm., Fieldiana Bot. 28(1): 133. 1951. *J. A. Steyermark 59655*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo).

Stegolepis terramarensis Steyerm., Ann. Missouri Bot. Gard. 71: 301. 1984. *J. A. Steyermark & F. Delascio 129197*; 30 Mar.–1 Apr. 1983; Venezuela, T.F. Amazonas, Cerro Marahuaca; 2,580–2,600 m; VEN (holo).

RHAMNACEAE

Colubrina pittieriana Steyerm., Fieldiana Bot. 28(4): 971. 1957, nom. nov.

Colubrina venezuelensis Steyerm.; Fieldiana Bot. 28(2): 355. 1952. *T. González s.n.*; n.d.; Venezuela, Distr. Federal, alrededores de Caracas; 1,600–1,800 m; F (holo).

Gouania wurdackii Steyerm., Ann. Missouri Bot. Gard. 75: 1065. 1988. *J. J. Wurdack & J. V. Monachino 39810*; 12 Dec. 1955; Venezuela, Bolívar, Distr. Cedeño, Cerro San Borja; 100 300 m; MO (holo), NY, VEN.

Rhamnus acuminata Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 42496*; 25 Dec. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina, summit, Cañon Grande; 1,050–1,150 m; MO (3291195), NY (holo).

Rhamnus chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 451. 1967. *J. A. Steyermark 75946*; 21–22 June 1953; Venezuela, Bolívar, Apacara-tepui, Chimantá Massif; 2,450–2,500 m; NY (holo).

Rhamnus longipes Steyerm., Ann. Missouri Bot. Gard. 75: 1066. 1988. *R. S. Cowan & J. J. Wurdack 31388*; 10 Feb. 1951; Venezuela, T.F. Amazonas, Serranía Parú; 2,000 m; NY (holo).

Rhamnus marahuacensis Steyerm. & Maguire, Acta Bot. Venez. 14(3): 22. 1984; *J. A. Steyermark et al. 126049*; 2 Feb. 1982; Venezuela, T.F. Amazonas, Dept. Atabapo, Cerro Marahuaca; 2,480–2,500 m; NY, VEN (holo).

Rhamnus microreticulata Maguire & Steyerm., ined. mss. = *R. neblinensis* Maguire & Steyerm., 1989.

Rhamnus neblinensis Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 37040*; 4 Jan. 1954; Venezuela, T.F. Amazonas, Cerro de la Neblina, summit; 1,800 m; MO (3291187), NY (holo).

Rhamnus psilocarpa Maguire & Steyerm., Mem. New York Bot. Gard. 50: in press. 1989. *B. Maguire et al. 37230*; 10 Jan. 1954; Venezuela, T.F. Amazonas, Cerro de la Neblina, summit; 1,700–2,000 m; MO (3291189), NY (holo).

Rhamnus sipapoensis Steyerm., Ann. Missouri Bot. Gard. 75: 1066. 1987. *B. Maguire & L. Politi 28656*; 26–28 Jan. 1949; Venezuela, T.F. Amazonas, Cerro Sipapo (Paraque) rim head of S basin; 1970 m; NY (holo), MO.

Rhamnus subpedunculata Maguire & Steyerm., ined. mss. = *R. acuminata* Maguire & Steyerm., 1989.

RHIZOPHORACEAE

Hypogyneae Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 184. 1983, tribe nov.

Sterigmapetalum Kuhlmann subg. *Balsamocaulon* Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 190. 1983, subg. nov.

Sterigmapetalum exappendiculatum Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 188. 1983. *B. Maguire et al. 46876*; 20–21 Aug. 1962; Venezuela, Bolívar, La Escalera, Alto Río Cuyuni, Río Uiri-Yuk; 1,000 m; NY, VEN (holo).

Sterigmapetalum guianense Steyerm., Fieldiana Bot. 28(2): 422. 1952. *J. A. Steyermark 60658*; 27 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo).

Sterigmapetalum guianense Steyerm. subsp. *ichunense* Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 188. 1983. *J. A. Steyermark 90428*; 29 Dec. 1961; Venezuela, Bolívar, Sierra Ichun; 500–625 m; NY, US, VEN (holo).

Sterigmapetalum heterodoxum Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 192. 1983. *J. A. Steyermark 99409*; 21 July 1967; Venezuela, Falcón, Sierra de San Luis, Montaña de Paraquariba, entre de Hotel Parador y Curimagua; 1,300 m; US, VEN (holo).

Sterigmapetalum resinosum Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 190. 1983. *J. A. Steyermark & E. Dunsterville 104569*; 27–28 Dec. 1970; Venezuela, Bolívar, Cerro Uei, km 121.5 S of El Dorado; 1,050 m; US (holo).

Sterigmapetalum tachirense Steyerm. & Liesner, Ann. Missouri Bot. Gard. 70: 190. 1983. *J. A. Steyermark et al. 120032*; 11 Nov. 1979; Venezuela, Táchira, Cerro Azul, at Cerro Las Minas, 18 km SE of Santa Ana; 1,200–1,380 m; MO (3466058), VEN (holo).

ROSACEAE

Amelanchier canadensis (L.) Medic. f. *nuda* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 772. 1938. *E. J. Palmer & J. A. Steyermark 40317*; 5 July 1933; U.S.A., Missouri, Mercer Co., 5 mi. S of Linesville; GH (holo).

Rosa setigera Michx. f. *alba* Steyerm., Rhodora 54: 254. 1952. *J. A. Steyermark 72011*; 7 July 1951; U.S.A., Missouri, Reynolds Co., 4 mi. SE of Bunker, along Bee Fork; F (holo), GH, MO.

Rosa setigera Michx. f. *inermis* Palmer & Steyerm.,

Ann. Missouri Bot. Gard. 22: 569. 1935. *E. J. Palmer 39039*; 26 Apr. 1931; U.S.A., Missouri, Bollinger, Patton; GH (holo).

Rosa setigera Michx. var. *serena* Palmer & Steyerm., Ann. Missouri Bot. Gard. 22: 569. 1935. *E. J. Palmer & J. A. Steyermark 41642*; 2 July 1933; U.S.A., Missouri, Ripley Co., Ponder; GH (holo).

Rubus flagellaris Willd. var. *occidualis* Bailey f. *roseus* Steyerm., Rhodora 62: 130. 1960. *J. A. Steyermark 84212*; 8 May 1957; U.S.A., Missouri, Bollinger Co., in valley of creek tributary to Castor River, NW of Buchanan Post Office; UMO (holo).

Rubus flagellaris Willd. f. *roseo-plenus* Palmer & Steyerm., Brittonia 10: 114. 1958. *E. J. Palmer 59655*; 3 May 1955; U.S.A., Missouri, Barton Co., 0.5 mi. SE of Libera; F (holo) = *R. flagellaris* var. *occidualis* Bailey f. *roseo-plenus* (Palmer & Steyerm.) Steyerm., 1960.

Rubus hadrocarpus Standl. & Steyerm., Fieldiana Bot. 24(4): 477. 1946. *P. C. Standley 86270*; 6 Feb. 1941; Guatemala, Dept. San Marcos, Barranco Eminencia; 2,500–2,700 m; F (holo).

Rubus hadrocarpus Standl. & Steyerm. f. *adenophorus* Standl. & Steyerm., Fieldiana Bot. 24(4): 478. 1946. *J. A. Steyermark 49859*; 31 July 1942; Guatemala, Dept. Huehuetenango, Cruz de Limón; 2,600–3,000 m; F (holo).

Rubus pensilvanicus Poir. f. *albinus* Palmer & Steyerm., Brittonia 10: 114. 1958. *J. A. Steyermark 78868*; 23 July 1955; U.S.A., Missouri, Howell Co., 6 mi. NE of West Plains, 5 mi. SSE of White Church; F (holo), GH, MO, US.

RUBIACEAE

Alibertia acuminata (Benth.) Sandw. var. *obtusiuscula* Steyerm., Mem. New York Bot. Gard. 12(3): 223. 1965. *L. Aristeguieta 5264*; 30 Jan. 1950; Venezuela, Bolívar, Ciudad Bolívar; VEN (holo).

Alibertia davidsei Steyerm., Ann. Missouri Bot. Gard. 66: 903. 1979. *G. Davidse & A. González 12910*; 8–9 May 1977; Venezuela, Apure, Distr. Pedro Camejo, 11 km E of Paso de San Pablo, 2 km ENE of Fundo Picachón, along Río Capanapano; 45 m; MO (268781), VEN (holo).

Alibertia latifolia Benth. var. *paragueniana* Steyerm., Mem. New York Bot. Gard. 12(3): 225. 1965. *J. J. Wurdack & J. Monachino 39784*; 10 Dec. 1955; Venezuela, Bolívar, Río Paragueni; 90 m; NY (holo).

Alibertia myrciifolia (Spruce) K. Schum. var. *tepuiensis* Steyerm., Mem. New York Bot. Gard. 12(3): 226. 1965. *B. & C. K. Maguire 40009*; 22 Nov. 1954; Brazil, Terr. Rio Branco, Serra Tepequem; 800 m; NY (holo).

Alibertia triloba Steyerm., Mem. New York Bot. Gard. 12(3): 227. 1965. *S. S. Tillett et al. 45180*; 7 Aug. 1960; Guyana, upper Mazaruni River basin, Mt. Ayanganna; 900–1,100 m; NY (holo).

Alseis microcarpa Standl. & Steyerm., Fieldiana Bot. 28(3): 565. 1953. *J. A. Steyermark 62232*; 19 Apr. 1945; Venezuela, Monagas, Montaña de Aguacate, along Quebrada de Pajarral; 600–900 m; F (holo).

Alseis trichocarpa Standl. & Steyerm., Fieldiana Bot. 28(3): 566. 1953. *J. A. Steyermark 57713*; 31 July–1 Aug. 1944; Venezuela, Bolívar, 1–10 km NW of Upata on road to San Felix; F (holo) = *A. labatiodes* Karst. ex Schumann, 1974.

Amaioua brevidentata Steyerm., Mem. New York Bot. Gard. 12(3): 216. 1965. *J. A. Steyermark 89802*; 20 Oct. 1961; Venezuela, Aragua, Parque Nacional Henri Pittier, Rancho Grande Biology Station, towards Pico Guacamayo; 1,500–1,700 m; VEN (holo).

Amaioua guianensis Aublet var. *macrantha* Steyerm., Mem. New York Bot. Gard. 12(3): 216. 1965. *B. Maguire et al. 42025*; 11 Nov. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina, Camp 3; 700 m; NY (holo).

Amphidasya intermedia Steyerm., Mem. New York Bot. Gard. 23(1): 319. 1972. *F. R. Fosberg & N. C. Fassett 21825*; 20 Apr. 1944; Colombia, Dept. Santander, E of Cimatara, 17 km WNW of Landazuri; 230–330 m; US (holo), NY.

Amphidasya neblinae Steyerm., Mem. New York Bot. Gard. 23(1): 320. 1972. *B. Maguire et al. 60295*; 1 Dec. 1965; Brazil; Amazonas, Rio Negro, Rio Cauaburi, Rio Tucano, base of Serra de Neblina; MO (2029484), NY (holo), VEN.

Aphanocarpus Steyerm., Mem. New York Bot. Gard. 12(3): 263. 1965, gen. nov.

Aphanocarpus steyermarkii (Standl.) Steyerm. f. *elongatus* Steyerm., Ann. Missouri Bot. Gard. 71: 331. 1984. *O. Huber & J. A. Steyermark 6945*; 26–29 Jan. 1983; Venezuela, Bolívar, Piar, Macizo de Chimantá; 2,000 m; VEN (holo).

Aphanocarpus steyermarkii (Standl.) Steyerm. f. *glabrior* Steyerm., Ann. Missouri Bot. Gard. 71: 330. 1984. *J. A. Steyermark et al. 115968*; 25 Feb. 1978; Venezuela, Bolívar, cumbre de Aprada-tepui; 2,460–2,500 m; VEN (holo).

Appunia longiloba Steyerm., Mem. New York Bot. Gard. 17(1): 358. 1967. *A. C. Smith 2384*; 1–4 Nov. 1937; Guyana, basin of Rupununi River, near mouth of Charwair Creek; NY (holo) = *Morinda longiloba* (Steyerm.) Steyerm., 1972.

Appunia sparsiflora Steyerm., Mem. New York. Bot. Gard. 17(1): 356. 1967. *Forest Dept. Field No. CAP 41*; 16 Feb. 1946; Guyana, Mazaruni Station; NY (holo) = *Morinda sparsiflora* (Steyerm.) Steyerm., 1972.

Appunia tenuiflora (Benth.) Jacks. & Hook. var. *leiophylla* Steyerm., Mem. New York Bot. Gard. 17(1): 358. 1967. *Forest Dept. Field No. WB 500*; Nov. 1948; Guyana, Iramaipang, Kanuku Mountains; 150 m; NY (holo) = *Morinda tenuiflora* (Benth.) Steyerm. var. *leiophylla* (Steyerm.) Steyerm., 1972.

Appunia venezuelensis Steyerm., Mem. New York Bot. Gard. 17(1): 356. 1967. *J. A. Steyermark 88277*; 10 Jan. 1961; Venezuela, Bolívar, Altiplanicie de Nuria; 400 m; VEN (holo) = *Morinda venezuelensis* (Steyerm.) Steyerm., 1972.

"*Arachnothrix*" *calycophylla* Steyerm., Mem. New York Bot. Gard. 17(1): 257. 1967. *J. A. Steyermark 57136*; 12 July 1944; Venezuela, Táchira, between Las Delicias and Paraquita, Río Táchira; 1,675–1,980 m; VEN (holo). Note: *Arachnothyrx* is the correct spelling.

"*Arachnothrix*" *costanensis* Steyerm., Mem. New York Bot. Gard. 17(1): 259. 1967. *J. A. Steyermark 61424*; 7 Mar. 1945; Venezuela, Anzoátegui, Cerro Peonia (Cerro Coroy); 1,000–1,450 m; VEN (holo).

"*Arachnothrix*" *fosbergii* Steyerm., Mem. New York Bot. Gard. 17(1): 255. 1967. *F. R. Fosberg & M. A. Giler 22964*; 10 Feb. 1945; Ecuador, Loja, Río Salado; NY (holo), US.

"*Arachnothrix*" *lojensis* Steyerm., Mem. New York Bot.

Gard. 17(1): 255. 1967. *F. R. Fosberg & M. A. Giler 23141*; Ecuador, Loja, Río San Francisco, Cordillera de Zamora (El Condor); NY (holo).

"*Arachnothrix*" *reflexa* (Benth.) Planch. var. *breviloba* Steyerm., Mem. New York Bot. Gard. 17(1): 253. 1967. *F. R. Fosberg 21418*; 14 Dec. 1943; Colombia, Norte de Santander, La Camarona; 1,700–1,850 m; NY (holo).

"*Arachnothrix*" *reflexa* (Benth.) Planch. var. *calycina* Steyerm., Mem. New York Bot. Gard. 17(1): 255. 1967. *J. Cuatrecasas & R. Romero Castañeda 24332*; 22 Sep. 1959; Colombia, Magdalena, Sierra Nevada de Santa Marta, Hoya del Río Donachui; 1,350–1,500 m; VEN (holo).

"*Arachnothrix*" *reflexa* (Benth.) Planch. var. *glandulifera* Steyerm., Mem. New York. Bot. Gard. 17(1): 253. 1967. *J. A. Steyermark 61317*; 1–2 Mar. 1945; Venezuela, Anzoátegui, along Río Zumbador, near base of Piedra Blanca; 800–1,000 m; VEN (holo).

"*Arachnothrix*" *reflexa* (Benth.) Planch. var. *meridensis* Steyerm., Mem. New York Bot. Gard. 17(1): 253. 1967. 1st cited: *L. Bernardi 985*; 21 Sep. 1953; Venezuela, Mérida, Santo Domingo; 1,600 m; depository not designated.

"*Arachnothrix*" *rugulosa* (Standl.) Steyerm. var. *tachirensis* Steyerm., Acta Bot. Venez. 6: 110. 1971. *L. Cardenas de Guavara 805*; 29 Dec. 1968; Venezuela, Táchira, Distr. Lobatera, Parque Río Conejo-Borota; MY (holo).

"*Arachnothrix*" *venezuelensis* Steyerm., Mem. New York Bot. Gard. 17(1): 256. 1967. *C. E. Chardon 179*; 26 Oct. 1940; Venezuela, Aragua, Carretera a Choroni; 1,300 m; VEN (holo).

Arcytophyllum nitidum (H.B.K.) Schlecht. subsp. *caracasanum* (H.B.K.) Steyerm. var. *culmenicolum* Steyerm., Acta Bot. Venez. 6: 119. 1971. *F. Tamayo 4509*; Sep. 1961; Venezuela, Mérida, teleferico de Mérida; VEN (holo).

Arcytophyllum nitidum (H.B.K.) Schlecht. f. *hispidum* Steyerm., Acta Bot. Venez. 6: 117. 1971. *J. A. Steyermark et al. 98558*; 20–23 May 1967; Venezuela, Táchira, Páramo de Tamá; 2,750–2,950 m; depository not designated.

Arcytophyllum vareschii Steyerm., Acta Bot. Venez. 6: 113. 1971. *V. Vareschi & K. Magdefrau 6850*; 3 Apr. 1958; Venezuela, Mérida, Pico Bolívar, Laguna Anteojos; 4,100 m; VEN (holo).

Arcytophyllum venezuelanum Steyerm., Acta Bot. Venez. 6: 120. 1971. *J. A. Steyermark & T. Koyama 102360*; 17 Dec. 1969; Venezuela, Mérida, estación La Aguada, between Mérida and Pico Espejo; 3,475 m; VEN (holo).

Bertiera aequaliramosa Steyerm., Mem. New York Bot. Gard. 17(1): 319. 1967. *G. P. Cooper 586*; Jan.–Mar. 1928; Panama, Prov. Bocas del Toro, Almirante, Buena Vista Camp on Chiriquí trail; 380 m; NY (holo).

Bertiera diversiramea Steyerm., Mem. New York Bot. Gard. 17(1): 319. 1967. *H. S. Irwin et al. 55299*; 1 Sep. 1963; Suriname, West Rivier, 4 km S Juliana Top, Wilhelmina Gebergte; 700 m; NY (holo).

Bertiera guianensis Aublet var. *glabriflora* Steyerm., Mem. New York Bot. Gard. 17(1): 318. 1967. *R. Spruce 4109*; 1855–1856; Perú, Prope Tarapoto; NY (holo).

Bertiera guianensis Aublet var. *leiophylla* Steyerm., Mem. New York Bot. Gard. 17(1): 318. 1967. *H. Pittier 5178*; Jan. 1912; Panamá, Prov. Chiriquí, vicinity of San Felix; 0–120 m; NY (holo).

Bertiera guianensis Aublet subsp. *pubiflora* Steyerm., Mem. New York Bot. Gard. 17(1): 318. 1967. *G. Klug 2164*; May–July 1931; Perú, Loreto, Río Zubineta mouth, Florida, Río Putpumayo; 180 m; NY (holo).

Borojoa duckei Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 478. 1966. *A. Ducke 1141*; 3 Oct. 1942; Brazil, Amazonas, Esperanca (Boca de Javary); NY, US (holo).

Borojoa universitatis Steyerm., Acta Bot. Venez. 3: 193. 1968. *L. Aristeguieta et al. 6466*; Nov. 1966; Venezuela, Miranda, Parque Naciónal de Guatopo; 650 m; VEN (holo).

Mitracarpus frigidus (Willd.) Schumann var. *peruvianus* Steyerm., Mem. New York Bot. Gard. 23: 780. 1972. *E. L. Evinger 513*; 21 Aug. 1943; Peru, Dept. Amazonas, 10 km E of Balzas; 2,300 m; NY (holo), US, VEN.

Mitracarpus pusillus Steyerm., Brittonia 30: 36. 1978. *H. S. Irwin et al. 27120*; 7 Mar. 1970; Brazil, Minas Gerais, Serra do Cabral, ca. 8 km W of Joaquim Felicio; 1,200 m; NY, UB (holo).

Morinda longipedunculata Steyerm., Ann. Missouri Bot. Gard. 75: 340. 1988. *G. Davidse & J. S. Miller 27327*; 9–14 July 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro de la Neblina, Cañon Grande; 350–400 m; MO (holo), VEN.

Neblinathamnus Steyerm., Mem. New York Bot. Gard. 10(5): 229. 1963, gen. nov.

Neblinathamnus aracamunianus Steyerm., Ann. Missouri Bot. Gard.: in press. 1989. *R. L. Liesner & F. Delascio 22153*; 19 Oct. 1987; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp; 1,550 m; MO (holo), VEN.

Neblinathamnus argyreus Steyerm., Mem. New York Bot. Gard. 10(5): 229. 1963. *B. Maguire et al. 42120*;

16 Nov. 1957; Venezuela, T.F. Amazonas, Cerro de la Neblina; NY (holo).

Neblinathamnus brasiliensis Steyerm., Mem. New York Bot. Gard. 23(1): 309. 1972. *N. T. Silva & U. Brazao 60907*; 26 Jan. 1966; Brazil, Amazonas, Serra Pirapucú; 1,300 m; NY (holo).

Neblinathamnus glabratus Steyerm., Mem. New York Bot. Gard. 10(5): 231. 1963. *B. Maguire et al. 37011*; 30 Dec. 1953; Venezuela, T.F. Amazonas, Cerro de la Neblina; NY (holo).

Pagamea acrensis Steyerm., Brittonia 33: 385. 1981. *N. A. Rosa 706*; 10 Feb. 1976. Brazil, Acre, Cruziero do Sul, Projecto RADAM-Ponto 10-SB-18-2D; IAN, VEN (holo).

Pagamea anisophylla Standl. & Steyerm., Fieldiana Bot. 28(3): 584. 1953. *J. A. Steyermark 58461*; 8 Sep. 1944; Venezuela, T.F. Amazonas, Sanariapo; 100 m; F (holo).

Pagamea auyantepuiensis Steyerm., Fieldiana Bot. 28: 584. 1953. *G. H. H. Tate 1365*; Dec. 1937–Jan. 1938; Venezuela, Bolívar, Mt. Auyan-tepui; 2,200 m; F (holo) = *Coryphothamnus auyantepuiensis* (Steyerm.) Steyerm., 1967.

Pagamea brevipedunculata Steyerm., Mem. New York Bot. Gard. 12(3): 283. 1965. *B. Maguire 33070*; 10–12 Jan. 1952; Venezuela, Bolívar, Cerro Guaiquinima, North Valley; 1,600–1,700 m; NY (holo).

Pagamea capitata Benth. subsp. *conferta* (Standl.) Steyerm. f. *breviloba* Steyerm., Mem. New York Bot. Gard. 12(3): 281. 1965. *B. Maguire et al. 29573*; 20 Nov. 1950; Venezuela, T.F. Amazonas, Cerro Duida, Río Cunucunuma, above Culebra; 1,400 m; NY (holo).

Pagamea coriacea Spruce var. *acuta* Steyerm., Mem. New York Bot. Gard. 12(3): 273. 1965. *R. E. Schultes & I. Cabrera 19367*; 14 May 1953; Colombia, Vaupés, Río Vaupés, between Mitu and Jauarete, Yutica; US (holo).

Pagamea coriacea Spruce var. *pubescens* Steyerm., Mem. New York Bot. Gard. 12(3): 273. 1965. *A Ducke 683*; 22 Mar. 1941; Brazil, Amazonas, Rio Negro inferior, Acajutaba; NY, US (holo).

Pagamea diceras Steyerm., Mem. New York Bot. Gard. 12(3): 281. 1965. *R. S. Cowan & J. J. Wurdack 31241*; 4 Feb. 1941; Venezuela, T.F. Amazonas, Serranía Parú; 2,000 m; NY (holo).

Pagamea duidana Standl. & Steyerm., Fieldiana Bot. 28(3): 586. 1953. *G. H. H. Tate 567*; 1 Jan. 1929; Venezuela, T.F. Amazonas, Mt. Duida, Central Camp; 1,600 m; F (holo), NY.

Pagamea dudleyi Steyerm., Phytologia 31(2): 226. 1975. *T. R. Dudley 13543*; 31 July 1969; Perú, Dept. Huanuco, SW slope of Río Llulla Pichas watershed, on ascent of Cerros del Sira; 1,850 m; NA, VEN (holo).

Pagamea guianensis Aublet var. *macrocarpa* Steyerm., Mem. New York Bot. Gard. 12(3): 278. 1965. *E. L. & R. R. Little, Jr. 9533*; 4 Mar. 1945; Colombia, Comisario de Caqueta, 8 km SE of Tres Esquinas, Solano, on Río Caqueta below mouth of Río Orteguaza; 200 m; NY (holo), US.

Pagamea harleyi Steyerm., Kew Bull. 38(2): 317. 1983. *R. Harley et al. 17069*; Jan.–Apr. 1974; Brazil, Bahia; CEPEC (holo), MO (2397731).

Pagamea jauaensis Steyerm., Mem. New York Bot. Gard. 23: 883. 1972. *J. A. Steyermark 97928*; 22–27 Mar. 1967; Venezuela, Bolívar, Cerro Jaua; 1,922–2,100 m; VEN (holo).

Pagamea magniflora Steyerm., Mem. New York Bot. Gard. 12(3): 285. 1965. *B. Maguire 33427*; 15 May 1952; Venezuela, Bolívar, Ilu-tepui, between N Peak and Central Plateau; 2,450–2,550 m; NY (holo).

Pagamea pauciflora Standl. & Steyerm., Fieldiana Bot. 28(3): 588. 1953. *J. A. Steyermark 60888*; 7 Dec. 1944; Venezuela, Bolívar, Carrao-tepui; 2,470–2,500 m; F (holo).

Pagamea plicata Spruce var. *multinervia* Steyerm., Mem. New York Bot. Gard. 12(3): 274. 1965. *L. Bernardi 1690*; 5 Sep. 1954; Venezuela, Bolívar, region de Uriman; 340–380 m; VEN (holo).

Pagamea plicatiformis Steyerm., Mem. New York Bot. Gard. 12(3): 274. 1965. *Ll. Williams 14190*; 9 Feb. 1942; Venezuela, T.F. Amazonas, Alto Río Negro, Guainía, selva de Maroa; 127 m; F (holo).

Pagamea puberula Steyerm., Mem. New York Bot. Gard. 12(3): 276. 1965. *A. Ducke 8462* (*RB22951*); 21 Aug. 1907; Brazil, Pará, Campos do Chicodaca; US (holo).

Pagamea reducta Steyerm., Mem. New York Bot. Gard. 12(3): 283. 1965. *K. D. Phelps & C. B. Hitchcock 366*; 1–15 Feb. 1948; Venezuela; Bolívar, Uaipan-tepui; 1,900 m; NY (holo), VEN.

Pagamea standleyana Steyerm., Fieldiana Bot. 28(3): 589. 1953. *J. A. Steyermark 59634*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo).

Pagamea uniflora Steyerm., Mem. New York Bot. Gard. 12(3): 284. 1965. *J. A. Steyermark 74877*; 13 Apr. 1953; Venezuela, Bolívar, Chimantá Massif, NW part of Abacapa-tepui; depository not designated.

Pagamea velutina Steyerm., Mem. New York Bot. Gard. 12(3): 275. 1965. *B. Maguire & L. Politi 28536*; 21 Jan. 1949; Venezuela, T.F. Amazonas, Cerro Sipapo (Paraque), near Camp Savannah; 1,500 m; NY (holo).

Pagameopsis Steyerm., Mem. New York Bot. Gard. 12(3): 267. 1965, gen nov.

Pagameopsis maguirei Steyerm., Mem. New York Bot. Gard. 12(3): 267. 1965. *J. A. Steyermark & J. J. Wurdack 1020*; 21 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui, Caño Mojado; 2,030–2,150 m; NY (holo), VEN.

Pagameopsis maguirei Steyerm. subsp. *neblinensis* Steyerm., Mem. New York Bot. Gard. 12(3): 270. 1965. *B. Maguire et al. 37130*; 6 Jan. 1954; Venezuela, T.F. Amazonas, Cerro de la Neblina, 5 km W of Cumbre Camp, summit; 1,900 m; NY (holo).

Pagameopsis maguirei Steyerm. subsp. *neblinensis* Steyerm. var. *angustifolius* Steyerm., Mem. New York Bot. Gard. 12(3): 270. 1965. *B. Maguire et al. 36948*; 27 Dec. 1953; Venezuela, T.F. Amazonas, Cerro de la Neblina, E of Camp 3; 1,700 m; NY (holo), VEN.

Pagameopsis maguirei Steyerm. subsp. *neblinensis* Steyerm. var. *pirapucuensis* Steyerm., Ann. Missouri Bot. Gard. 74: 108. 1987. *N. T. Silva & U. Brazao 60880*; 20 Jan. 1966; Brazil, Serra Pirapucú; 1,300 m; NY (holo). Note: This specimen is also holotype for *Psychotria canescens* Steyerm., however the dates and elevation differ.

Pagameopsis maguirei Steyerm. subsp. *pusillus* Steyerm., Ann. Missouri Bot. Gard. 74: 106. 1987. *R. L. Liesner 16013*; 16–18 Feb. 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro de la Neblina, Camp III, NW Plateau; 1,750–1,850 m; MO (holo—3327370), VEN.

Pagameopsis maguirei Steyerm. subsp. *pusillus* Steyerm. var. *glabrus* Steyerm., Ann. Missouri Bot. Gard. 74: 108. 1987. *E. Cardona 3096*; 5 Dec. 1972;

Venezuela, T.F. Amazonas, summit of Cerro Avispa, Río Siapa; 1,510 m; NY (holo), VEN.

Palicourea aculeifera Steyerm., Acta Bot. Venez. 2: 331. 1967. *J. A. Steyermark 60377*; 20–21 Nov. 1944; Venezuela, Bolívar, Auyan-tepui; 1,065–1,220 m; F, VEN (holo) = *P. longistipulata* subsp. *chrysorrhachis* (Bremek.) Steyerm., 1972.

Palicourea amapaensis Steyerm., Mem. New York Bot. Gard. 23: 765. 1972. *J. Murca Pires et al. 50386*; 20 Aug. 1961; Brazil, Terr. Amapá, near Rio Araguari between Cachoieras Travessão and Santa Maria; NY (holo).

Palicourea angustifolia H.B.K. var. *glabricaulis* Steyerm., Acta Bot. Venez. 6: 174. 1971, also Mem. New York Bot. Gard. 23: 771. 1972. *L. Ruíz Terán & L. E. Rodriquez Poveda 3746*; 10 Mar. 1967; Venezuela, Lara, Distr. Iribarren, Mun. Juarez, La Cuchilla; 1,500 m; VEN (holo).

Palicourea bostrychostachya Steyerm., Acta Bot. Venez. 6: 158. 1971. *Funck & Schlim 1500*; Nov. 1846; Venezuela, Mérida, San Jacinto; P (holo).

Palicourea buntingii Steyerm., Acta Bot. Venez. 6: 148. 1971. *J. A. Steyermark et al. 101900*; 5 Apr. 1968; Venezuela, Apure, Cerro La Cristalina; 300 m; NY, VEN (holo).

Palicourea buntingii Steyerm. var. *glabrior* Steyerm., Acta Bot. Venez. 6: 151. 1971. *L. Bernardi 7437*; 22 Mar. 1959; Venezuela, Zulia, Río Negro; 1,000 m; MER (holo), MO (2763590).

Palicourea canaguensis Steyerm., Acta Bot. Venez. 6: 157. 1971. Type not designated in the original description. Note: Fl. Venez. cites the type as: *J. A. Steyermark 56412*; n.d.; Venezuela, Mérida, Quebrada de Los Salichales, afluente del Río Canaguá, al SO de Canagua; depository not indicated.

Palicourea cardonae Steyerm., Mem. New York Bot. Gard. 23: 759. 1972. *F. Cardona 1383*; 16–24 Feb. 1946; Brazil, Rio Castanho, afluente de Rio Padauiri que cae al Rio Negro; 100–140 m; US (holo).

Palicourea chimo Standl. & Steyerm., Fieldiana Bot. 28(3): 591. 1953. *J. A. Steyermark 55371*; 6 Feb. 1944; Venezuela, Lara, between Las Sabanetas and ridge top by boundary line of Lara–Trujillo, above Humocaro Bajo; 2,600–2,800 m; F (holo) = *Palicourea demissa* Standl. var. *chimo* (Standl. & Steyerm.) Steyerm., 1971.

Palicourea crocea (Sw.) Roemer & Schultes var. *riparia* (Benth.) Griseb. f. *heterodoxa* Steyerm., Mem. New York Bot. Gard. 23: 739. 1972. *J. Lanjouw & J. C. Lindeman 802*; 12 Oct. 1948; Suriname, km 12.2 Moengo; NY (holo), U.

Palicourea ctenocalyx Steyerm., Acta Bot. Venez. 6: 165. 1971. *J. A. Steyermark et al. 100763*; 12 Jan. 1968; Venezuela, Táchira, cabeceras del Río Quinimari; 2,500–2,800 m; VEN (holo).

Palicourea demissa Standl. var. *chimo* (Standl. & Steyerm.) Steyerm. f. *pubens* Steyerm., Acta Bot. Venez. 6: 163. 1971. *J. A. Steyermark & M. Rabe 96816*; 28 Aug. 1966; Venezuela, Táchira, entre Michelena y Boca del Monte; 2,000–2,400 m; VEN (holo).

Palicourea dunstervilleorum Steyerm., Acta Bot. Venez. 6: 175. 1971. *J. A. Steyermark et al. 98810*; 22–24 May 1967; Venezuela, Táchira, Páramo de Tamá; 2,300–2,450 m; VEN (holo).

Palicourea ensiformis Steyerm., Acta Bot. Venez. 6: 172. 1971. *J. A. Steyermark 57192*; 13 July 1944; Venezuela, Táchira, Montaña of Río Táchira at base of Páramo de Tamá; 2,430 m; VEN (holo).

Palicourea flexiramea Steyerm., Acta Bot. Venez. 6: 159. 1971. *R. Velasco & M. Ramia 627*; 2 Apr. 1950; Venezuela, Mérida, entre La Azulita y Ejido; MY (holo).

Palicourea foldatsii Steyerm., Mem. New York Bot. Gard. 23: 777. 1972. *E. Foldats 3670*; 4 Sep. 1960; Venezuela, T.F. Amazonas, Santa Cruz, Río Atabapo; NY, VEN (holo).

Palicourea garciae Steyerm., Acta Bot. Venez. 6: 167. 1971. *F. Garcia 55*; 12 May 1951; Venezuela, Aragua, Fila del Paraiso, Rancho Grande; 1,375 m; VEN (holo).

Palicourea glabriflora Steyerm., Mem. New York Bot. Gard. 23: 735. 1972. *B. Maguire et al. 37490*; 4 Feb. 1954; Venezuela, T.F. Amazonas, Casiquiare, ríos Pacimoni–Yatua, Piedra Tururumeri; 110–220 m; NY (holo).

Palicourea guianensis Aublet subsp. *occidentalis* Steyerm., Mem. New York Bot. Gard. 23: 729. 1972. *De la Cruz 1638*; July 1922; Guyana, between the Demerare and Berbice rivers; NY (holo).

Palicourea guianensis Aublet subsp. *occidentalis* Steyerm. f. *glabra* Steyerm., Mem. New York Bot. Gard. 23: 730. 1972. *F. R. Fosberg 21211*; 10 Oct. 1943; Colombia; Dept. Nariño, along Río Guagui, 1–2 km S of Barbacoas; 40–50 m; NY (holo), US.

Palicourea guianensis Aublet subsp. *occidentalis* Steyerm. var. *glabrescens* Steyerm., Mem. New York Bot. Gard. 23: 730. 1972. *C. Játiva & C. Epling 682*; 8 July 1964; Ecuador, Prov. Esmeraldas, San Lorenzo; UCLA, VEN (holo).

Palicourea huberi Steyerm., Pittieria 9: 8. 1981. *G. Davidse et al. 17359*; 8 May 1979; Venezuela, T.F. Amazonas, Dept. Atabapo, Caño Yagua at Cucurital de Yagua; 120 m; MO, VEN (holo).

Palicourea insignis Steyerm., Acta Bot. Venez. 6: 176. 1971, also Mem. New York Bot. Gard. 23: 776. 1972. *T. Lasser 1221*; 22 Aug. 1944; Venezuela, Trujillo, El Páramo cerca de Escuque; VEN (holo).

Palicourea irwinii Steyerm., Mem. New York Bot. Gard. 23: 758. 1972. *H. S. Irwin et al. 47354*; 5 Aug. 1960; Brazil, Amapá, 5 km SE of Clevelandia; NY (holo).

Palicourea lasseri Steyerm., Acta Bot. Venez. 6: 171. 1971. *T. Lasser 1156*; Aug. 1944; Venezuela, Trujillo, entre Boconó y Trujillo; VEN (holo).

Palicourea meridensis Steyerm., Acta Bot. Venez. 6: 155. 1971. *J. A. Steyermark & M. Rabe 97090*; 1 Sep. 1966; Venezuela, Mérida, Río Capaz, arriba de La Azulita; 2,100–2,400 m; VEN (holo).

Palicourea nana Steyerm., Acta Bot. Venez. 6: 170. 1971. *J. A. Steyermark et al. 101055*; 16 Jan. 1968; Venezuela, Táchira, entre Las Copas y Alto de Fila de Tierra Negra; 2,879–2,880 m; VEN (holo).

Palicourea nubicola Steyerm., Acta Bot. Venez. 6: 168. 1971. *J. A. Steyermark & M. Rabe 97243*; 3–4 Sep. 1966; Venezuela, Trujillo, 30 km from Boconó; 2,300–2,500 m; VEN (holo).

Sipanea Aublet subsect. *Phanerotricha* Steyerm., Mem. New York Bot. Gard. 17(1): 266. 1967, subsect. nov.

Sipanea ayangannensis Steyerm., Mem. New York Bot. Gard. 17(1): 269. 1967. *S. S. Tillett et al. 45114*; 12 Aug. 1960; Guyana, upper Mazaruni River, Mt. Ayanganna; 1,418 m; NY (holo).

Sipanea carrenoi Steyerm., Ann. Missouri Bot. Gard. 71: 333. 1984. *J. A. Steyermark et al. 115598*; 22 Feb. 1978; Venezuela, Bolívar, Gran Sabana; 1,130 m; MO (3223163), VEN (holo).

Sipanea cowanii Steyerm., Mem. New York Bot. Gard. 17(1): 265. 1967. *R. S. Cowan & T. R. Soderstrom 1863*; 18 Feb. 1962; Guyana, Kaieteur Plateau, near Johnson's View, Kaieteur Falls, Potaro Gorge; 425 m; US (holo).

Sipanea gleasonii Steyerm., Mem. New York Bot. Gard. 17(1): 265. 1967. *H. A. Gleason 431*; 18 June–8 July 1921; Guyana, Tumatumari; NY (holo).

Sipanea glomerata H.B.K. var. *paucinervia* Steyerm., Mem. New York Bot. Gard. 17(1): 282. 1967. *B. Maguire et al. 30458*; 28 Dec. 1950; Venezuela, T.F. Amazonas, 30 km above Playa Alta; 200 m; NY (holo).

Sipanea ovalifolia Bremek. var. *villosissima* Steyerm., Brittonia 36: 159. 1984. *G. Cremers 6460*; 26 Apr. 1980; French Guiana, 4 km SE de Saul; 600–700 m; CAY (holo), VEN.

Sipanea prancei Steyerm., Brittonia 33: 400. 1981. *G. T. Prance et al. 10528*; 14 Feb. 1971; Brazil, Roraima, Indian trail from Surucucu, near Maita Indian village; NY (holo), VEN.

Sipanea pratensis Aublet var. *dichotoma* (H.B.K.) Steyerm. f. *brachycarpa* Steyerm., Mem. New York Bot. Gard. 17(1): 276. 1967. *B. Maguire & L. Politi 27324*; 19 Nov. 1948; Venezuela, T.F. Amazonas, Danta (Tapir) Falls, Río Cuao, Río Orinoco; 125 m; VEN (holo).

Sipanea pratensis Aublet var. *dichotoma* (H.B.K.) Steyerm. f. *breviflora* Steyerm., Mem. New York Bot. Gard. 17(1): 277. 1967. *J. A. Steyermark 89276*; 1–11 Feb. 1961; Venezuela, Bolívar, cerro between Las Nieves and base of slopes SE of Cerro Picacho Altiplanicie de Nuria; 100–300 m; VEN (holo).

Sipanea pratensis Aublet var. *dichotoma* (H.B.K.) Steyerm. f. *glabriloba* Steyerm., Mem. New York Bot. Gard. 17(1): 276. 1967. *J. J. Wurdack & L. Adderley 42916*; n.d.; Venezuela, T.F. Amazonas, Yavita–Pimichin trail near Yavita, Río Atabapo; 125–140 m; NY (holo).

Sipanea pratensis Aublet var. *dichotoma* (H.B.K.) Steyerm. f. *glabrior* Steyerm., Mem. New York Bot. Gard.

17(1): 2777. 1967. *J. J. Wurdack & J. V. Monachino 39823*; 12 Dec. 1955; Venezuela, Bolívar, Cerro San Borja; 100–300 m; NY (holo).

Sipanea pubinoda Steyerm., Mem. New York Bot. Gard. 17(1): 278. 1967. *L. Williams 15656*; 29 May 1942; Venezuela, T.F. Amazonas, Capihuara, Alto Casiquiare; 120 m; VEN (holo).

Sipanea setacea Steyerm., Ann. Missouri Bot. Gard. 74: 114. 1987. *O. Huber et al. 8246*; 31 Aug. 1983; Venezuela, Bolívar, Distr. Piar, Cerro El Venado, 20 km E of Canaima; 1,300 m; NY (holo).

Sipaneopsis Steyerm., Mem. New York Bot. Gard. 17(1): 284. 1967, gen. nov.

Sipaneopsis foldatsii Steyerm., Mem. New York Bot. Gard. 17(1): 288. 1967. *E. Foldats 3678*; 4 Sep. 1960; Venezuela, T.F. Amazonas, Santa Cruz, Río Atabapo, Río Atacavi; VEN (holo).

Sipaneopsis huberi Steyerm., Ernstia 23: 37. 1984. *O. Huber & E. Medina 5786*; 6 Feb. 1981; Venezuela, T.F. Amazonas, Dept. Río Negro; 350 m; MO (3235600), VEN (holo).

Sipaneopsis maguirei Steyerm., Mem. New York Bot. Gard. 17(1): 287. 1967. *B. Maguire et al. 41438*; 13 Sep. 1957; Colombia, Cacagual Savanna, Río Atabapo, between San Fernando de Atabapo and Caño Temi; 135 m; NY (holo).

Sipaneopsis morichensis Steyerm., Mem. New York Bot. Gard. 17(1): 286. 1967. *B. Maguire et al. 30878*; 14 Jan. 1951; Venezuela, T.F. Amazonas, Cerro Moriche, Río Ventuari; 800 m; NY (holo).

Sipaneopsis pacimoniensis Steyerm., Mem. New York Bot. Gard. 17(1): 289. 1967. *B. Maguire et al. 37570*; 7 Feb. 1954; Venezuela, T.F. Amazonas, Río Pacimoni; 100–140 m; NY (holo).

Sipaneopsis wurdackii Steyerm., Mem. New York Bot. Gard. 17(1): 288. 1967. *B. Maguire et al. 37639*; 9 Feb. 1954; Venezuela, T.F. Amazonas, Caño Hechimoni; 100–130 m; NY (holo).

Spermacoce perijaënsis Steyerm., Acta Bot. Venez. 8: 252. 1973. *J. A. Steyermark et al. 105747*; 31 Mar. 1972; Venezuela, Zulia, Sierra de Perija; 1,140 m; VEN (holo).

Sphinctanthus insignis Steyerm., Brittonia 33: 400. 1981. *R. P. Belem & R. S. Pinheiro 2738*; 8 Oct. 1966; Brazil, Bahia, Guaratinga; VEN (holo), NY.

Stachyarrhena acutiloba Steyerm., Mem. New York Bot. Gard. 12(3): 220. 1965. *A. Ducke 1844*; 24 Nov. 1945; Brazil, Amazonas, Tabatinga; NY (holo).

Stachyarrhena reticulata Steyerm., Mem. New York Bot. Gard. 12(3): 220. 1965. *B. Maguire et al. 36259*; 18 Nov. 1953; Venezuela, T.F. Amazonas, river margin between San Fernando de Atabapo and Cacagual; 130 m; NY (holo).

Tocoyena brevifolia Steyerm., Mem. New York Bot. Gard. 12(3): 196. 1965. *Ll. Williams 16039*; 7 May 1943; Venezuela, T.F. Amazonas, baja Sanariapo, laja Carestia; 120 m; VEN (holo), F.

Tocoyena costanensis Steyerm., Bol. Soc. Venez. Ci. Nat. 25(106): 73. 1963. *E. Delgado 160*; 22 May 1938; Venezuela, Distr. Federal, Avila; VEN (holo).

Tocoyena costanensis Steyerm. subsp. *andina* Steyerm., Acta Bot. Venez. 6: 125. 1971. *L. Ruíz Terán* 1433; n.d.; Venezuela, Mérida, La Cuchilla; VEN (holo).

Tocoyena cuatrecasasii Steyerm., Acta Bot. Venez. 4(1): 113. 1964. *J. Cuatrecasas 9198*; 6 Apr. 1940; Colombia, Comisaria del Caqueta, Cordillera Oriental, Sucre, Quebrada de la Calana; 1,000–1,100 m; US (holo).

Tocoyena guianensis K. Schum. var. *communis* Steyerm., Mem. New York Bot. Gard. 12(3): 194. 1965. *H. S. Irwin et al. 47620*; 18 Aug. 1960; Brazil, Terr. Amapa, Río Oiapoque opposite Pedro Alice; NY (holo).

Tocoyena guianensis K. Schum. var. *glabriuscula* Steyerm., Mem. New York Bot. Gard. 12(3): 195. 1965. *B. Maguire & J. J. Wurdack 34923*; Venezuela, T.F. Amazonas, Piedra Cucuy, Río Negro; 100–200 m; depository not designated.

Tocoyena orinocensis Standl. & Steyerm., Fieldiana Bot. 28(3): 617. 1953. *J. A. Steyermark 58442*; 8 Sep. 1944; Venezuela, T.F. Amazonas, below mouth of Río Sanariapo, along Orinoco River; 100 m; F (holo).

Tresanthera thyrsiflora Steyerm., Bol. Soc. Venez. Ci. Nat. 25(107): 248. 1964. *A. L. Bernardi 5829A*; 23 Nov. 1956; Venezuela, Miranda, selvas pluviales del Guatopo; 400–600 m; NY (holo).

Yutajea Steyerm., Ann. Missouri Bot. Gard. 74: 676. 1987, gen. nov.

Yutajea liesneri Steyerm., Ann. Missouri Bot. Gard. 74: 676. 1987. *R. L. Liesner & B. K. Holst 21826*; 10 Mar. 1987; Venezuela, T.F. Amazonas, Dept. Atures, 5–8 km NW of Yutaje settlement, 3 km W of Río Coro Coro, W of Serranía de Yutaje; MO (holo), VEN.

RUTACEAE

Amyris ignea Steyerm., Fieldiana Bot. 28(2): 272. 1952, nom. nov.

Casimiroa emarginata Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 165. 1944. *J. A. Steyermark 36931*; 28 Feb. 1940; Guatemala, Dept. San. Marcos, Tajumulco, Volcán Tajumulco; 2,300–2,800 m; F (holo).

Diomma fruticosa Steyerm., Fieldiana Bot. 28(2): 272. 1952. *J. A. Steyermark 60820*; 20 Nov. 1944; Venezuela, Bolívar, Río Karuai, between La Laja and Santa Teresita de Kavanayen; 1,220 m; F (holo).

Esenbeckia echinoidea Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 164. 1944. *P. C. Standley 74456*; 15 Oct. 1940; Guatemala, Dept. Chiquimula, between Ramírez and Cumbre de Chiquimula; 400–600 m; F (holo).

Galipea guatemalensis Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 165. 1944. *J. A. Steyermark 39448*; 14 Apr. 1940; Guatemala, Dept. Izabal, Río Dulce; F (holo).

Lubaria szczerbanii Steyerm., Brittonia 32: 17. 1980. *J. A. Steyermark et al. 117221*; 23 24 May 1978; Venezuela, Bolívar, Cerro Guaiquinima, a lo largo del afluente de Río Carapo, río arriba del Salto Szcerbanari; 730–750 m; US, VEN (holo).

Rauia subtruncata Steyerm., Ann. Missouri Bot. Gard. 75: 315. 1988. *R. L. Liesner & A. González 5991*; 1 3 Aug. 1978; Venezuela, Bolívar, 20–25 km SW of Manteco, on road to San Pedro de las Dos Bocas; 200 m; MO (holo—3396481), VEN.

Ravenia ruellioides Oliver var. *ptariana* Steyerm., Fieldiana Bot. 28(2): 273. 1952. *J. A. Steyermark 59511*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo).

Raveniopsis aracaënsis Kallunki & Steyerm., Brittonia 39: 409. 1987. *G. T. Prance et al. 29016*; 12 Feb. 1984; Brazil, Amazonas, Serra Aracá, plateau of N Massif, S extreme of N part of Aracá; F, INPA (holo), K, MO, NY, US.

Raveniopsis breweri Steyerm., Brittonia 32: 48. 1980.

J. A. Steyermark et al. 116166; 28 Feb. 1978; Venezuela, Bolívar, Auyan-tepui, N de la Misión de Camarata; 1,950 m; VEN (holo).

Raveniopsis cowaniana Steyerm. & Luteyn, Ann. Missouri Bot. Gard. 71: 316. 1984. *J. Luteyn 9413*; 7–8 Feb. 1984; Venezuela, Río Negro, Cerro de la Neblina; 1,880 m; VEN (holo).

Raveniopsis jauaensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32(132/133): 338. 1976. *J. A. Steyermark et al. 108876*; 10 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua; 1,410 m; VEN (holo).

Raveniopsis liesneri Steyerm., Ann. Missouri Bot. Gard. 75: 317. 1988. *R. L. Liesner 16605*; 15 18 Nov. 1984; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro de la Neblina, Camp 4; 780 m; MO (holo—3405796), VEN.

Rutaneblina Steyerm. & Luteyn, Ann. Missouri Bot. Gard. 71: 314. 1984, gen. nov.

Rutaneblina pusilla Steyerm. & Luteyn, Ann. Missouri Bot. Gard. 71: 314. 1984. *J. A. Steyermark 129798*; 8 Feb. 1984; Venezuela, T.F. Amazonas, Cerro de Neblina; 1,880 m; MO (3223149), VEN (holo).

Zanthoxylum aguilarii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 146. 1940. *P. C. Standley 63209*; 21 Jan. 1939; Guatemala, Dept. Sacatepéquez, above Dueñas; 1,600–1,800 m; F (holo).

Zanthoxylum nubium Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 243. 1940. *J. A. Steyermark 31430*; 8 Nov. 1939; Guatemala, Dept. Chiquimula, Volcán de Quezaltepeque, 3–4 mi. NE of Quezaltepeque; 1,500 2,000 m; F (holo).

Zanthoxylum pallidum Steyerm., Fieldiana Bot. 28(2): 273. 1952. *J. A. Steyermark 56580*; 18 May 1944; Venezuela, Mérida, above Tabay, 2,285–2,745 m; F (holo).

Zanthoxylum tachirense Steyerm., Fieldiana Bot. 28(2): 274. 1952. *J. A. Steyermark 57111*; 7 July 1944; Venezuela, Táchira, above La Grita, below Páramo de la Negra; 2,430–2,510 m; F (holo).

SABIACEAE

Meliosma dives Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 60. 1944. *J. A. Steyermark 46773*; May 1942; Guatemala, Dept. Suchitepéquez, Volcán de Santa Clara, above Chicacao; 1,250 m; F (holo).

Meliosma maxima Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 61. 1944. *J. A. Steyermark 38170*; Mar. 1940; Guatemala, Dept. Izabal, between Bananera and La Presa, Montaña del Mico; 300 m; F (holo).

Meliosma nubicola Steyerm. & Lasser, Bol. Soc. Venez. Ci. Nat. 26: 463. 1966. *J. A. Steyermark & M. Farinas 90967*; 21 Oct. 1962; Venezuela, Distr. Federal, Altos de No León; 2,400 m; VEN (holo).

Meliosma pittieriana Steyerm., Fieldiana Bot. 28(2): 354. 1952. *J. A. Steyermark 61524*; 18 Mar. 1945; Venezuela, Anzoátegui, Quebrada Seca; 1,000–1,100 m; F (holo).

Meliosma tepuiensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 448. 1967. *J. A. Steyermark 75701*; 19 June 1953; Venezuela, Bolívar, Apacara-tepui, Chimantá Massif; 1,900–1,950 m; NY (holo).

SALICACEAE

Salix cordata Muehlenb. f. *mollis* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 770. 1938. *J. A. Steyermark 12491*; 4 Aug. 1936; U.S.A., Missouri, Dent Co.; MO (holo—1174271).

Salix cordata Muehlenb. f. *subintegra* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 770. 1938. *J. A. Steyermark 20910*; 28 Nov. 1936; U.S.A., Missouri, Phelps Co., shore of lake at Yaney Mills Spring; MO (holo) = *S. rigida* Muehlenb. f. *subintegra* (Palmer & Steyerm.) Steyerm., 1960.

Salix sericea Marsh f. *glabra* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 769. 1938. *J. A. Steyermark 12548*; 4 Aug. 1936; U.S.A., Missouri, Dent Co.; MO (holo—1130660). Note: The original description erroneously cites two different collections with the number 12918 as both the holotype and paratype.

SANTALACEAE

Thesium tepuiense Steyerm., Fieldiana Bot. 28(1): 225. 1951. *J. A. Steyermark 60237*; 15–17 Nov. 1944; Venezuela, Bolívar, between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo), MO (1621266).

SAPINDACEAE

Allophylus parimensis Steyerm., Ann. Missouri Bot. Gard. 75: 333. 1988. *J. A. Steyermark 107033*; 18 Apr.–23 May 1973; Venezuela, T.F. Amazonas, Sierra Parima, vecinidades de Simarawochi, Río Matacuni; 795 830 m; MO (holo—2669225), VEN.

Cupania andina Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 463. 1966. *J. A. Steyermark 56301*; 4 May 1944; Venezuela, Mérida, between Mucuty and Mucuchachi; 1,065–2,430 m; VEN (holo).

Cupania kavanayena Steyerm., Fieldiana Bot. 28(2): 343. 1952. *J. A. Steyermark 60912*; 11 Dec. 1944; Venezuela, Bolívar, Quebrada de Kavanayen; 1,200–1,220 m; F (holo) = *Matayba kavanayena* (Steyerm.) Steyerm., 1966.

Cupania kukenanica Steyerm., Fieldiana Bot. 28(2): 344. 1952. *J. A. Steyermark 59182*; 2 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,065 m; F (holo).

Cupania roraimae Steyerm., Fieldiana Bot. 28(2): 346. 1952. *J. A. Steyermark 59107*; 1 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,065–1,220 m; F (holo).

Cupania tepuiensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 446. 1967. *J. A. Steyermark & J. J. Wurdack 1133*; 26 Feb. 1955; Venezuela, Bolívar, Agparaman-tepui, Chimantá Massif; 1,880–1,955 m; MO (3021963), NY (holo).

Dipterodendron venezuelense Steyerm., Fieldiana Bot. 28(2): 346. 1952. *J. A. Steyermark 56569*; 15 May 1944; Venezuela, Mérida, between San Isidro Alto and Santa Cruz de Mora; 760–1,800 m; F (holo) = *Dilodendron elegans* (Radlk.) Gentry & Steyerm., 1987.

Llagunoa venezuelana Steyerm., Fieldiana Bot. 28(2): 347. 1952. *J. A. Steyermark 56507*; 14 May 1944; Venezuela, Mérida, above El Molino; 2,010–2,135 m; F (holo).

Matayba affinis Steyerm., Ann. Missouri Bot. Gard. 75: 1067. 1988. *G. Davidse et al. 17011*; 30 Apr.–1 May 1979; Venezuela, T.F. Amazonas, Dept. Atabapo, Cucurital de Caname, S bank of the middle part of Caño Caname; 100 m; MO (holo 2744469), VEN.

Matayba chimantensis Steyerm., Mem. New York Bot. Gard. 17(1): 447. 1967. *J. A. Steyermark 74656*; 25 Mar. 1953; Venezuela, Bolívar, Río Apacara, Apacara-tepui, Chimantá Massif; 400 m; MO (2011418), VEN (holo).

Maytayba jauaensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32(132/133): 347. 1976. *J. A. Steyermark et al. 109673*; 28 Feb.–1–2, 5 Mar. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,810–1,880 m; VEN (holo) = *M. oligandra* Sandw., 1988.

Matayba longipes Radlk. subsp. *tepuiensis* Steyerm., Ann. Missouri Bot. Gard. 75: 1069. 1988. *R. S. Cowan & J. J. Wurdack 31450*; 13 Feb. 1951; Venezuela, T.F. Amazonas, Serranía Parú, Caño Asisi, Top Camp to Caño Camp; 1,400 m; MO (holo—2997923), NY.

Matayba oligandra Sandw. var. *occidentalis* Steyerm., Ann. Missouri Bot. Gard. 75: 1069. 1988. *B. Maguire & L. Politi 28399*; 17 July 1949; Venezuela, T.F. Amazonas, Caño Grande, Río Cuao, Río Orinoco; 125 m; MO (holo—2934861), NY.

Matayba ptariana Steyerm., Fieldiana Bot. 28(2): 350. 1952. *J. A. Steyermark 60203*; 15 Nov. 1944; Venezuela, Bolívar, Salto de Iwaracaru-meru; 1,015 m; F (holo).

Matayba ptariana Steyerm. subsp. *guaiquinimae* Steyerm., Ann. Missouri Bot. Gard. 74: 635. 1987. *O. Huber 10388*; 27 Mar. 1985; Venezuela, Bolívar, Dept. Heres, Meseta de Guaiquinima; 1,400 m; MO (holo—3382924), NY, VEN.

Matayba reducta Steyerm., Fieldiana Bot. 28(2): 351. 1952. *J. A. Steyermark 60365*; 20–21 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma; 1,065–1,220 m; F (holo).

Matayba yutajensis Steyerm., Ann. Missouri Bot. Gard. 75: 1070. 1988. *B. & C. K. Maguire 35143*; 11 Feb. 1953; Venezuela, T.F. Amazonas, Serranía Yutaje, NW Ridge; 1,400 m; MO (holo—2934874), NY, VEN.

Matayba sororopaniana Steyerm., Fieldiana Bot. 28(2): 352. 1952. *J. A. Steyermark 60201*; 15 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 1,656–1,980 m; F (holo).

Matayba venezuelana Steyerm., Fieldiana Bot. 28(2): 353. 1952. *J. A. Steyermark 60663*; 28 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo).

Paullinia manarae Steyerm., Acta Bot. Venez. 3: 202. 1968. *B. J. Manara s.n.*; 4 Oct. 1965; Venezuela, Distr. Federal, Naiguatá, Lomas de Las Delicias, Quebrada de Basenilla y Quebrada Guayoyo; 1,390–1,500 m; VEN (holo).

Paullinia mexiae Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 155. 1940. *Y. Mexia 8855*; 19 Nov. 1937; Mexico, Guerrero, Distr. Adama, Temisco, Barranco de la Guacamaya, Sierra Madre del Sur, N of Río Balsas; F (holo), MO (1181481).

Paullinia mollicoma Steyerm., Fieldiana Bot. 28(2): 353. 1952. *J. A. Steyermark 60579*; 25 Nov. 1944; Venezuela, Bolívar, Quebrada O-paru-ma; 915–1,065 m; F (holo).

Paullinia naiguatensis Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 457. 1966. *J. A. Steyermark 91874*; 2 Nov. 1963; Venezuela, Distr. Federal, Cerro Naiguatá; VEN (holo).

Paullinia nuriensis Steyerm., Acta Bot. Venez. 3: 179. 1968. *J. A. Steyermark 89005*; 3 Feb. 1961; Venezuela, Bolívar, Cerro El Picacho, Altiplanicie de Nuria; 620 m; NY (holo).

Paullinia toxicodendroides Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 460. 1966. *J. A. Steyermark 92079*; 15–19 Nov. 1963; Venezuela, Distr. Federal, Cerro Naiguatá; 1,000–1,300 m; VEN (holo).

Serjania hispida Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 171. 1944. *J. A. Steyermark 43926*; 19 Feb. 1942; Guatemala, Dept. Alta Verapaz, along road between San Cristóbal and Chixoy; 1,200–1,300 m; F (holo).

Serjania lobulata Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 14. 1943. *P. C. Standley 73715*; Oct. 1940; Guatemala, Dept. Chiquimula, near the divide on road from Zacapa to Chiquimula; 660 m; F (holo).

Serjania macrocarpa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 15. 1943. *W. A. Kellerman 7532*; 23 Feb. 1908; Guatemala, Dept. Izabal, Los Amates; F (holo).

Serjania phaseoloides Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 171. 1944. *J. A. Steyermark 50908*; 18 Aug. 1942; Guatemala, Dept. Huehuetenango, along Río Cuilco between Cuilo and San Juan; 1,200–1,300 m; F (holo).

Talisia caudata Steyerm., Ann. Missouri Bot. Gard. 75: 1072. 1988. *B. Maguire & L. Politi 28615*; 25 Jan. 1949; Venezuela, T.F. Amazonas, Cerro Sipapo, trail from Base Camp; 125 m; MO (holo—3304133, 3304132), NY.

Talisia glandulifera Steyerm., Ann. Missouri Bot. Gard. 75: 1072. 1988. *S. Mori et al. 15027*; 1 Oct. 1982; French Guiana, Saul, Monte La Fumée; 200–400 m; MO (holo—3427739), NY.

Talisia heterodoxa Steyerm., Ann. Missouri Bot. Gard. 75: 1073. 1988. *R. L. Liesner & A. González 11151*; n.d.; Venezuela, Bolívar, Represa Guri islands, 6–18 km S of dam; 220–240 m; MO (holo—2926530), VEN.

Talisia maruayana Steyerm., Ann. Missouri Bot. Gard. 75: 1070. 1988. *R. L. Liesner & B. K. Holst 20394*; 26 Apr. 1986; Venezuela, Bolívar, Amaruay-tepui; 550–810 m; MO (holo—3446405, 3446406, 3446407, 3446408), VEN. (mss. name = *T. amaruayensis*).

Talisia morilloi Steyerm., Acta Bot. Venez. 10: 237. 1975. *G. Morillo et al. 3339*; 16 July 1973; Venezuela, Topo Tacamahaco (Tamanaco), Quebrada Río Grande; 900–1,000 m; VEN (holo).

Talisia pentantha Steyerm., Ann. Missouri Bot. Gard. 75: 1075. 1988. *F. Ehrendorfer 74104-23*; 4 Oct. 1974; Venezuela, Bolívar, Canaima, W of Avensa Camp; 500 m; VEN (holo).

Talisia sancarlosiana Steyerm., Ann. Missouri Bot. Gard. 75: 1075. 1988. *L. Marcano Berti & P. Alcedo 119-979*; 11–17 Mar. 1970; Venezuela, T.F. Amazonas, between San Carlos and Solano; MER (holo).

Talisia tiricensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 448. 1967. *J. A. Steyermark & J. J. Wurdack 116*; 16 Jan. 1955; Venezuela, Bolívar, Río Tirica (Río Aparuren), above Techine-mero; 470 m; NY (holo).

Toulicia anomala Steyerm., Ann. Missouri Bot. Gard. 75: 1076. 1988. *J. J. Wurdack & J. V. Monachino 41253*; 17 Jan. 1956; Venezuela, Bolívar, Río Suapure, middle Orinoco; 110–120 m; MO (holo—3310903), NY.

SAPOTACEAE

Chrysophyllum ficoides Steyerm., Acta Bot. Venez. 2: 279. 1967. *J. A. Steyermark 93431*; 5 May 1964; Venezuela, Bolívar, Auyan-tepui; VEN (holo).

Chrysophyllum monachinoanum Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 432. 1966. *J. A. Steyermark et al. 92333*; 29–30 Dec. 1963; Venezuela, Bolívar, Cerro Venamo; 950–1,150 m; VEN (holo).

Pouteria auyantepuiensis Steyerm., Acta Bot. Venez. 2:

278. 1967. *J. A. Steyermark 93917*; Venezuela, Bolívar, Auyan-tepui, 1,850 m; depository not designated.
Pouteria spectabilis Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 436. 1966. *J. A. Steyermark & S. Nilsson 768*; 24–25 Apr. 1960; Venezuela, Bolívar, near headwaters of Río Aponguao, NE of Luepa; 1,200 m; VEN (holo).
Pouteria venamoënsis Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 434. 1966. *J. A. Steyermark et al. 92414*; 29–30 Dec. 1963; Venezuela, Bolívar, Cerro Venamo; 950–1,150 m; VEN (holo).

SARRACENIACEAE

Heliamphora heterodoxa Steyerm., Fieldiana Bot. 28(1): 239. 1951. *J. A. Steyermark 59766*; 2 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,000–2,200 m; F (holo).
Heliamphora heterodoxa Steyerm. var. *exappendiculata* Maguire & Steyerm., Mem. New York Bot. Gard. 29: 54. 1978. *J. J. Wurdack 34262*; 29 Jan. 1953; Venezuela, Bolívar, Chimantá-tepui, NW slope of Churi-tepui; 2,050 m; NY (holo).
Heliamphora heterodoxa Steyerm. var. *exappendiculata* f. *glabella* Steyerm., Ann. Missouri Bot. Gard. 71: 311. 1984. *J. A. Steyermark 93712*; 11 May 1964; Venezuela, Bolívar, Auyan-tepui; 1,600–1,800 m; VEN (holo).
Heliamphora minor Gleason f. *laevis* Steyerm., Ann. Missouri Bot. Gard. 71: 311. 1984. *F. Cardona 2661*; Jan. 1949; Venezuela, Bolívar, Cerro Auyan; 2,100 m; VEN (holo).

SAXIFRAGACEAE

Heuchera puberula Mack. & Bush f. *glabrata* Steyerm., Rhodora 51: 117. 1949. *J. A. Steyermark 66615*; 2 Oct. 1948; U.S.A., Missouri, Shannon Co., Jam Up Bluff along Jack's Fork of Current River, 4 mi. N of Teresita, 6 mi. NW of Monteer; F (holo).

SCROPHULARIACEAE

Calceolaria yuparum Steyerm., Acta Bot. Venez. 10: 243. 1975. *J. A. Steyermark et al. 105721*; 22–23, 28 Mar. 1972; Venezuela, Zulia, Sierra de Perija; 1,440–1,460 m; US, VEN (holo) = *C. mexicana* Benth. subsp. *prostrata* (Kränzlin) Molau, 1988.
Castilleja altorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 85. 1944. *J. A. Steyermark 49908*; Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Chemalito, Sierra de los Cuchumatanes; 3,100–3,150 m; F (holo).
Pedicularis canadensis L. f. *albescens* Steyerm., Rhodora 54: 258. 1952. *J. A. Steyermark 67499*; 1 May 1949; U.S.A., Missouri, Wright Co., along route 5, 2.5 mi. S of Mansfield; F (holo).
Penstemon digitalis (Sweet) Nutt. f. *baueri* Steyerm., Rhodora 43: 663. 1941. *J. A. Steyermark 27665*; 1 July 1939; U.S.A., Missouri, Osage Co., 3 mi. NE of Westphalia, along Maries River; F (holo).
Russelia laciniata Standl. & Steyerm., Field Mus. Bot. Ser. 22(5): 379. 1940. *J. A. Steyermark 37982*; 16 Mar. 1940; Guatemala, Dept. San Marcos, above Finca El Porvenir, along Río Cabús near Cueva de las Palomas, Volcán Tajumulco; 1,300–1,500 m; F (holo).

SELAGINELLACEAE

Selaginella gigantea Steyerm. & A. R. Smith, Ann. Missouri Bot. Gard. 73: 209. 1986. *J. A. & C. Steyermark 95418*; 1 Apr. 1966; Venezuela, Carabobo, entre Los Tanques y La Toma, Río San Jían; 750 m; US (holo), VEN.

SIMAROUBACEAE

Picramnia caracasana Engler f. *tomentella* Steyerm., Fieldiana Bot. 28(2): 274. 1952. *J. A. Steyermark 57019*; 25 June 1944; Venezuela, Distr. Federal, E of El Junquito; 1,980–2,130 m; F (holo).
Picramnia nuriensis Steyerm., Acta Bot. Venez. 3: 177. 1968. *J. A. Steyermark 88591*; 19–23 Jan. 1961; Venezuela, Bolívar, Cerro El Picacho; Altiplanicie de Nuria; 450–620 m; NY (holo).
Picramnia tristamina Steyerm., Fieldiana Bot. 28(2): 275. 1952. *Ll. Williams 13918*; 23 Jan. 1942; Venezuela, T.F. Amazonas, camino de Yavita; 128 m; F (holo).

SMILACACEAE

Smilax auraimensis Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 472. 1966. *J. A. Steyermark 90823*; 16 Jan. 1962; Venezuela, Bolívar, Sierra Auraima; 400 m; VEN (holo).
Smilax chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 440. 1967. *J. A. Steyermark 74652*; 25 Mar. 1953; Venezuela, Bolívar, Río Apacara, Apacara-tepui, Chimantá Massif; 400 m; NY (holo).
Smilax duidae Steyerm., Fieldiana Bot. 28(1): 154. 1951. *J. A. Steyermark 58057*; 26 Aug. 1944; Venezuela, T.F. Amazonas, Cerro Duida, Caño Negro; 260–610 m; F (holo).
Smilax jauaensis Steyerm. & Maguire, Mem. New York Bot. Gard. 23: 854. 1972. *J. A. Steyermark 98073*; 22 27 Mar. 1967; Venezuela, Bolívar, Cerro Jaua; 1,922–2,100 m; VEN (holo).
Smilax lasseriana Steyerm., Fieldiana Bot. 28(1): 154. 1951. *J. A. Steyermark 60121*; Venezuela, Bolívar, Sororopan-tepui; 2,255 m; F (holo).
Smilax pittieriana Steyerm., Fieldiana Bot. 28(1): 155. 1951. *J. A. Steyermark 60251*; 15–17 Nov. 1944; Venezuela, Bolívar, on mesa between Ptari-tepui and Sororopan-tepui; 1,615 m; F (holo).
Smilax staminea Griseb. f. *obtusata* Steyerm., Fieldiana Bot. 28(1): 156. 1951. *J. A. Steyermark 59695*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,700–1,800 m; F (holo).

SOLANACEAE

Athenaea locuples Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 375. 1940. *J. A. Steyermark 37953*; 16 Mar. 1940; Guatemala, Dept. San Marcos, above Finca El Porvenir, along Río Cabus, near Cueva de las Palomas, Volcán Tajumulco; 1,300–1,500 m; F (holo) = *Witheringia stramonifolia* H.B.K., 1974.
Athenaea macrocardia Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 375. 1940. *J. A. Steyermark 30004*; 14 Oct. 1939; Guatemala, Dept. Zacapa, Río Lima, Sierra de Las Minas, below Finca Alejandría; 2,000 m; F (holo) = *A. viscosa* (Schrader) Fern., 1974.
Cestrum aristeguietae Steyerm., Acta Bot. Venez. 6: 86. 1971. *J. A. & C. Steyermark 95463*; 2 Apr. 1966; Venezuela, Carabobo, Río San Gean, S of Borburata; 350 m; US VEN (holo).
Cestrum pariense Steyerm., Acta Bot. Venez. 1(2): 62. 1966. *J. A. Steyermark & G. Agostini 91026*; 18

July 1962; Venezuela, Sucre, Cerro Patao; 850 m; VEN (holo).

Cyphomandra bolivarensis Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 441. 1966. *J. A. Steyermark 60094*; 13 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,225 2,255 m; VEN (holo).

Cyphomandra rojasiana Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 376. 1940. *J. A. Steyermark 33743*; 8 Jan. 1940; Guatemala, Dept. Quezaltenango, Volcán Santa María; 1,300–1,500 m; F (holo).

Cyphomandra villosa Steyerm., Phytologia 9(6): 348. 1964. *M. Acosta Solis 7743*; 12 Apr. 1944; Ecuador, Prov. Loja, region central, Las Chinchas; 2,250 m; F (holo).

Lycianthes barbatula Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 228. 1947. *J. A. Steyermark 46653*; 23 May 1942; Guatemala, Dept. Suchitepéquez, Volcán de Santa Clara; 1,250–2,650 m; F (holo).

Lycianthes chiapensis (Brandegee) Standl. var. *sparsistellata* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 274. 1940. *J. A. Steyermark 31555*; 10 Nov. 1939; Guatemala, Dept. Chiquimula, Cerro Tixixí; 500–1,500 m; F (holo) = *L. chiapensis* (Brandegee) Standl. var. *chiapensis*, 1976.

Lycianthes orogenes Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 229. 1947. *J. A. Steyermark 52104*; 20 Sep. 1942; Guatemala, Dept. Chimaltenango, SW slope Volcán Fuego; 1,200–1,600 m; F (holo).

Markea costanensis Steyerm., Acta Bot. Venez. 3: 211. 1968. *J. A. Steyermark 94382*; 12 Oct. 1965; Venezuela, Distr. Federal, between Colonia Tovar–Junquito road and Hacienda El Limón; 1,300–1,500 m; VEN (holo).

Markea grandiflora Steyerm., Phytologia 9(6): 349. 1964. *M. Acosta Solis 7009*; 18 Jan. 1944; Ecuador, Prov. Pichincha, bajada de Loche a Condor Mackay, Cordillera Occidental; 2,700–3,100 m; F (holo).

Markea reticulata Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 461. 1967. *J. A. Steyermark 75157*; 19 Apr. 1953; Venezuela, Bolívar, Abacapa-tepui, Chimantá Massif; 1,200 1,600 m; VEN (holo).

Vierembergia espinosae Steyerm., Phytologia 9(6): 349. 1964. *R. Espinosa 1076*; 24 Nov. 1946; Ecuador, Prov. Loja, Namanda; 1,500 m; F (holo).

Physalis amica Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 231. 1947. *J. A. Steyermark 36175*; 20 Feb. 1940; Guatemala, Dept. San Marcos, between La Vega ridge and NE slopes Volcán Tacaná, along Río Vega; 2,500–3,000 m; F (holo).

Physalis calidaria Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 231. 1947. *P. C. Standley 67488*; 4 Mar. 1939; Guatemala, Dept. Quezaltenango, Fuentes Georginas, W Volcán Zunil; 2,850 m; F (holo).

Physalis campanula Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 18. 1943. *J. A. Steyermark 36067*; Feb. 1940; Guatemala, Dept. San Marcos, Quebrada Canjula, between Sibinal and Canjula, Volcán Tacaná; 2,200–2,500 m; F (holo).

Physalis carnosa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 19. 1943. *J. A. Steyermark 37766*; Mar. 1940; Guatemala, Dept. San Marcos, Ocos; F (holo).

Physalis chimalteca Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(25): 232. 1947. *P. C. Standley 61803*; 3 Jan. 1939; Guatemala, Dept. Chimaltenango, Volcán de Acatenango, above Las Calderas; 2,400–2,700 m; F (holo) = *P. calidaria* Standl. & Steyerm., 1974.

Physalis lassa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 19. 1943. *J. A. Steyermark 32868*; Dec. 1939; Guatemala, Dept. Jalapa, between Jalapa and Montaña Miramundo; 1,500–2,000 m; F (holo).

Solanum alpicum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 232. 1947. *J. A. Steyermark 50303*; 8 Aug. 1942; Guatemala, Dept. Huehuetenango, Cerro Chemal, Sierra de los Cuchumatanes; 3,700–3,800 m; F (holo) = *S. demissum* Lindl., 1974.

Solanum decurtatum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(1): 20. 1943. *C. L. Lundell 2012*; Mar. 1933; Guatemala, Petén, Lago de Yaxha; F (holo) = *S. blodgetii* Chapman, 1974.

Solanum fontium Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 234. 1947. *P. C. Standley 67473*; 4 Mar. 1939; Guatemala, Dept. Quezaltenango, Fuentes Georginas, W Volcán Zunil; 2,850 m; F (holo).

Solanum huehuetecum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 234. 1947. *J. A. Steyermark 51039*; 23 Aug. 1942; Guatemala, Dept. Huehuetenango, above Democracia on trail to Jutal; 1,000 m; F (holo).

Solanum muenscheri Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 275. 1940. *W. C. Muenscher 12360*; 14 Apr. 1937; Guatemala, Dept. Sololá, near Santa María; 3,150 m; F (holo).

Solanum puberuloba Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 444. 1966. *J. A. Steyermark & S. Nilsson 185*; 15–17 Apr. 1960; Venezuela, Bolívar, Fila de La Danta; 1,200 m; VEN (holo).

Solanum rufistellatum Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 445. 1966. *J. A. Steyermark & S. Nilsson 178*; 15–17 Apr. 1960; Venezuela, Bolívar, Fila de La Danta; 1,200 m; VEN (holo).

Solanum verapazense Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 276. 1940. *P. C. Standley 69756*; 30 Mar. 1939; Guatemala, Dept. Baja Verapaz, N of Santa Rosa; F (holo) = *S. torvum* Swartz, 1974.

STAPHYLEACEAE

Turpinia multijuga Steyerm., Fieldiana Bot. 28(2): 341. 1952. *J. A. Steyermark 56455*; 10 May 1944; Venezuela, Mérida, road to El Molino, Cuesta de Rincón and Cuesta del Barro; 1,925–2,175 m; F (holo).

STERCULIACEAE

"*Buettneria*" *venezuelensis* Steyerm., Acta Bot. Venez. 3: 183. 1968. *J. A. Steyermark 87782*; 26 Nov. 1960; Venezuela, Terr. Delta Amacuro, between La Margarita and Puerto Miranda, Río Acure; 80–100 m; NY (holo). Note: *Byttneria* is the correct spelling.

Melochia humboldtiana Steyerm., Fieldiana Bot. 28(2): 365. 1952. *J. A. Steyermark 62436*; 1 May 1945; Venezuela, Sucre, between Cocollar and Guamal; 1,200 m; F (holo).

STYRACACEAE

Styrax andinus Steyerm., Pittieria 4: 12. 1972. *J.-P. Veillon 14*; 1971; Venezuela, Mérida, San Eusebio, La Carbonera; 2,600 m; VEN (holo).

Styrax costanus Steyerm., Fieldiana Bot. 28(3): 490.

1953. *J. A. Steyermark 61575*; 20 Mar. 1945; Venezuela, Anzoátegui, Bergantín, Cerro Peonia (Cerro Los Pajaritos); 1,600–1,800 m; F (holo).

Styrax duidae Steyerm., Fieldiana Bot. 28(3): 491. 1953. *J. A. Steyermark 58242*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida; 1,025 1,200 m; F (holo).

Styrax jauaensis Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 390. 1976. *J. A. Steyermark et al. 109574*; 27 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 2,228–2,250 m; VEN (holo).

Styrax longipedicellatus Steyerm., Acta Bot. Venez. 10: 242. 1975. *V. Barnes 43*; Apr.–June 1950; Venezuela, T.F. Amazonas, region del Duida y Marahuaca; VEN (holo).

Styrax tepuiense Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 456. 1967. *J. A. Steyermark & J. J. Wurdack 1028*; 21 Feb. 1955; Venezuela, Bolívar, Torono-tepui, Chimantá Massif; 2,030–2,150 m; NY (holo).

Styrax tepuiensis Steyerm. & Maguire subsp. *guaiquinimae* Maguire & Steyerm., Mem. New York Bot. Gard. 29(1): 218. 1978. *B. Maguire 32758*; 25 Dec. 1951; Venezuela, Bolívar, Río Paragua, Cerro Guaiquinima; NY (holo).

Styrax tepuiensis Steyerm. & Maguire subsp. *huachamacarii* Maguire & Steyerm., Mem. New York Bot. Gard. 29(1): 218. 1978. *B. Maguire et al. 30001*; 6 Dec. 1950; Venezuela, Terr. Amazonas, Cerro Huachamacari; NY (holo).

Styrax vulcanicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 264. 1940. *J. A. Steyermark 36801*; 27 Feb. 1940; Guatemala, Dept. San Marcos, between town of Tajumulco and Tecutla, NW slopes of Volcán Tajumulco; 1,800 2,500 m; F (holo).

Styrax wurdackiorum Steyerm., Acta Bot. Venez. 10: 241. 1975. *J. A. Steyermark et al. 106573*; 7 10 Dec. 1972; Venezuela, Bolívar, carretera El Dorado hacia Santa Elena de Uairen; 1,200–1,400 m; VEN (holo).

SYMPLOCACEAE

Symplocos abietorum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 221. 1947. *J. A. Steyermark 48482*; 9 July 1942; Guatemala, Dept. Huehuetenango, Rancho de Teja, Sierra de los Cuchumatanes; 3,330 m; F (holo).

Symplocos acananensis Steyerm., Ann. Missouri Bot. Gard. 74: 656. 1987. *J. A. Steyermark et al. 131868*; 1 3, 20 May 1986; Venezuela, Bolívar, vicinity of Guadequen, Río Acanán, affluent of Río Carrao, W of Cerro Los Hermanos; 470 m; MO (3514025), VEN (holo).

Symplocos chimantensis Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 459. 1967. *J. A. Steyermark & J. J. Wurdack 1100*; 23 Feb. 1955; Venezuela, Bolívar, Torono-tepui, Chimantá Massif; 1,955 2,090 m; NY (holo).

Symplocos culminicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 222. 1947. *J. A. Steyermark 31489*; 8 Nov. 1939; Guatemala, Dept. Chiquimula, Volcán de Quezaltepeque; 2,000 m; F (holo).

Symplocos jauaensis Steyerm. & Maguire, Mem. New York Bot. Gard. 23: 876. 1972. *J. A. Steyermark 98072*; 22–27 Mar. 1967; Venezuela, Bolívar, Cerro Jaua; 1,922–2,100 m; VEN (holo), NY.

Symplocos lasseri Steyerm., Fieldiana Bot. 28(3): 492. 1953. *T. Lasser & J. A. Steyermark 55103*; 30 Dec. 1943; Venezuela, Distr. Federal, Cordillera del Avila, above Caracas; 1,585–1,820 m; F (holo).

Symplocos neblinae Maguire & Steyerm., Mem. New York Bot. Gard. 29(1): 229. 1978. *B. Maguire et al. 42378*; 13 Dec. 1957; Venezuela, Terr. Amazonas, Cerro de la Neblina; 2,200 m; NY (holo).

Symplocos pittieriana Steyerm., Fieldiana Bot. 28(3): 492. 1953. *J. A. Steyermark 57335*; 15 July 1944; Venezuela, Táchira, base of Páramo de Tamá; 2,500–2,895 m; F (holo).

Symplocos roraimensis Steyerm., Fieldiana Bot. 28(3): 494. 1953. *J. A. Steyermark 58761*; 27 Sep. 1944; Venezuela, Bolívar, Mt. Roraima; 2,255–2,620 m; F (holo) = *S. pycnophylla* Sleumer, 1978.

Symplocos tamana Steyerm., Fieldiana Bot. 28(3): 495. 1953. *J. A. Steyermark 57340*; 15 July 1944; Venezuela, Táchira, base of Páramo de Tamá; 2,500–2,895 m; F (holo).

Symplocos vatteri Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 222. 1947. *J. A. Steyermark 48463*; 9 July 1942; Guatemala, Dept. Huehuetenango, Rancho de Teja, Sierra de los Cuchuamatanes; 3,330 m; F (holo).

Symplocos yapacanensis Steyerm., Acta Bot. Venez. 10: 242. 1975. *J. A. Steyermark & G. S. Bunting 103185*; 5 7 Mar 1970; Venezuela, T.F. Amazonas, Cerro Yapacana; 1,000–1,200 m; VEN (holo).

TAXODIACEAE

Taxodium distichum Rich. f. *confusum* Palmer & Steyerm., Ann. Missouri Bot. Gard. 25: 769. 1938. *J. A. Steyermark 11261*; 28 June 1936; U.S.A., Missouri, Wayne Co., Markham Springs, 3 mi. W of Williamsville; MO (holo).

TEPUIANTHACEAE

Tepuianthaceae Maguire & Steyerm., Mem. New York Bot. Gard. 29(2): 8. 1981, fam. nov.

Tepuianthus Maguire & Steyerm., Mem. New York Bot. Gard. 29(2): 9. 1981, gen. nov.

Tepuianthus aracensis Steyerm. & Maguire, Acta Amazonica 16/17: 219. 1986/1987. *J. Pipoly et al. 6838*; 18 Mar. 1984; Brazil, Amazonas, Serra Acacá, summit of southern massif; 1,200 m; INPA (holo), MO (3327363), NY.

Tepuianthus auyantepuiensis Maguire & Steyerm., Mem. New York Bot. Gard. 29(2): 10. 1981. *J. A. Steyermark et al. 116093*; 27 Feb. 1978. Venezuela, Bolívar, Auyan-tepui; 1,940 m; NY, VEN (holo).

Tepuianthus colombianus Maguire & Steyerm., Mem. New York Bot. Gard. 32: 16. 1981. *R. E. Schultes & I. Cabrera 15056*; 22–25 Jan. 1952; Colombia, Vaupés, near summit of Cerro Isibukuri; GH (holo).

Tepuianthus sarisarinamensis Maguire & Steyerm., Mem. New York Bot. Gard. 32: 16. 1981. *J. A. Steyermark et al. 109237*; 19–20 Feb. 1974; Venezuela, Meseta del Jaua, Cerro Sarisariñama; 1,350 m; NY, VEN (holo).

Tepuianthus sarisarinamensis Maguire & Steyerm. subsp. *duidensis* Maguire & Steyerm., Mem. New York Bot. Gard. 32: 18. 1981. *B. Maguire et al. 29543*; 19 Nov. 1950; Venezuela, T.F. Amazonas, Cerro Duida; 1,500 m; NY (holo).

Tepuianthus savannensis Maguire & Steyerm., Mem. New York Bot. Gard. 29(2): 14. 1981. *O. Huber et*

al. 3759; 7 May 1979; Venezuela, T.F. Amazonas, Dept. Atabapo, Caño Yagua; 120 m; VEN (holo); NY.

Tepuianthus yapacanensis Maguire & Steyerm., Mem. New York Bot. Gard. 29(2): 12. 1981. *B. Maguire et al. 30683*; 3 Jan. 1951; Venezuela, T.F. Amazonas, Cerro Yapacana; 120 m; NY (holo).

THEACEAE

Acopanea Steyerm., Ann. Missouri Bot. Gard. 71: 323. 1984, gen. nov.

Acopanea ahogadoi Steyerm., Ann. Missouri Bot. Gard. 71: 1984. *J. A. Steyermark et al. 129924*; 14–16 Feb. 1984; Venezuela, Bolívar, Piar, Macizo del Chimantá; 1,920 m; MO (3234986), NY, VEN (holo).

Bonnetia bolivarensis Steyerm., Ann. Missouri Bot. Gard. 74: 102. 1987. *O. Huber 9818*; 19 Nov. 1984; Venezuela, Bolívar, Ptari-tepui; 2,400 m; MO, VEN (holo).

Bonnetia chimantensis Steyerm., Ann. Missouri Bot. Gard. 71: 326. 1984. *J. A. Steyermark & J. J. Wurdack 680*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,090 m; F, NY, VEN (holo).

Bonnetia duidae Kobuski & Steyerm., J. Arnold Arbor. 29: 411. 1948. *J. A. Steyermark 58186*; 1 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida, summit, Brocchinia Hills; 1,700–1,980 m; F (holo), NY = *Neogleasonia duidae* (Kobuski & Steyerm.) Maguire, 1972.

Bonnetia euryanthera Steyerm., Ann. Missouri Bot. Gard. 74: 647. 1987. *J. A. Steyermark et al. 124311*; 14 Feb. 1981; Venezuela, Bolívar, Meseta de Jaua; 2,020 m; MO, NY (holo), VEN.

Bonnetia guaiquinimae Steyerm., Ann. Missouri Bot. Gard. 74: 102. 1987. *J. A. Steyermark 117421*; 26 May 1978; Venezuela, Bolívar, Cerro Guaiquinima; 1,250 m; MO, VEN (holo).

Bonnetia huberiana Steyerm., Ann. Missouri Bot. Gard. 71: 326. 1984. *J. A. Steyermark & J. J. Wurdack 633*; 9 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,165–2,180 m; F, NY, US, VEN (holo).

Bonnetia liesneri Steyerm., Ann. Missouri Bot. Gard.: in press, 1989. *R. L. Liesner & F. Delascio 22105*; 18 Oct. 1987; Venezuela, T.F. Amazonas, Dept. Río Negro, Cerro Aracamuni, Popa Camp; 1,550 m; MO (holo), VEN.

Bonnetia maguireorum Steyerm., Ann. Missouri Bot. Gard. 71: 330. 1984, nom. nov.

Bonnetia neblinensis Steyerm., Ann. Missouri Bot. Gard. 71: 330. 1984, nom. nov.

Bonnetia ptariensis Steyerm., Ann. Missouri Bot. Gard. 74: 102. 1987. *J. A. Steyermark et al. 115645*; 23 Feb. 1978; Venezuela, Bolívar, Ptari-tepui; MO, VEN (holo).

Bonnetia tepuiensis Kobuski & Steyerm., J. Arnold Arbor. 29: 399. 1948. *J. A. Steyermark 60871*; 5–6 Dec. 1944; Venezuela, Bolívar, Carrao-tepuí (Ptari-tepui); 1,675–1,980 m; F (holo), NY.

Bonnetia tepuiensis Kobuski & Steyerm. subsp. *minor* Steyerm., Ann. Missouri Bot. Gard. 71: 326. 1984. *J. A. Steyermark & J. J. Wurdack 990*; 20 Feb. 1955; Venezuela, Chimantá Massif; 1,975 m; F, NY, US, VEN (holo).

Bonnetia toronoensis Steyerm., Ann. Missouri Bot. Gard. 71: 327. 1984. *J. A. Steyermark & J. J. Wurdack 1047*; 21 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, Torono-tepui; 2,030–2,150 m; F, NY, US, VEN (holo).

Bonnetia tristyla Gleason subsp. *nervosa* Steyerm., Ann. Missouri Bot. Gard. 74: 103. 1987. *J. A. Steyermark & G. S. Bunting 103153*; 5 May 1970; Venezuela, T.F. Amazonas, Cerro Yapacana, below summit; 825 m; VEN (holo). Note: Superfluous publication in: Ann. Missouri Bot. Gard. 74: 649. 1987. *B. Maguire et al. 30632*; 2 Jan. 1951; Venezuela, T.F. Amazonas, Cerro Yapacana; NY, VEN (holo).

Laplacea fruticosa (Schrader) Kobuski var. *chimantae* Steyerm., Ann. Missouri Bot. Gard. 74: 650. 1987. *J. A. Steyermark & J. J. Wurdack 879*; 17 Feb. 1955; Venezuela, Bolívar, Chimantá Massif, central section, along W branch headwaters of Río Tirica above upper falls; 2,090 m; F, NY, VEN (holo).

Laplacea pubescens Planchon & Linden ex Triana & Planchon var. *minor* Steyerm., Ann. Missouri Bot. Gard. 74: 652. 1987. *B. Maguire et al. 30285*; 17 Dec. 1959; Venezuela, T.F. Amazonas, Cerro Huachamacari, between Summit Camp amd SW escarpment; 1,850 m; NY (holo).

Ternstroemia acrodantha Kobuski & Steyerm., Fieldiana Bot. 28(2): 381. 1952. *J. A. Steyermark 56582*; 18 May 1944; Venezuela, Mérida, above Tabay; 2,285–2,745 m; F (holo), GH.

Ternstroemia camelliifolia Linden & Planch. var. *minor* Kobuski & Steyerm., Field. Bot. 28(2): 383. 1952. *J. A. Steyermark 56979*; 19 June 1944; Venezuela, Distr. Federal, El Junquito, Cordillera de la Costa; 1,830 2,130 m; F (holo).

Ternstroemia unilocularis Kobuski & Steyerm., Fieldiana Bot. 28(2): 383. 1952. *J. A. Steyermark 61626*; 20 Mar. 1945; Venezuela, Anzoátegui, Cerro Paeonía (Cerro Los Pajaritos); 1,800–2,000 m; F (holo), GH.

THYMELAEACEAE

Daphnopsis dircoides Steyerm., Fieldiana Bot. 28(2): 420. 1952. *J. A. Steyermark 60136*; 14 Nov. 1944; Venezuela, Bolívar, Sororopan-tepui; 2,255 m; F (holo).

Daphnopsis ficina Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 254. 1940. *J. Garcia Salas 1442*; Jan. 1932; Guatemala, Dept. Guatemala, La Cienaguilla, San José Pinula; 1,600 m; F (holo).

Daphnopsis guaiquinimae Steyerm., Ann. Missouri Bot. Gard. 74: 652. 1987. *J. A. Steyermark et al. 117977*; 9 Apr. 1979; Venezuela, Bolívar, Cerro Guaiquinima; 1,650 m; MO, VEN (holo).

Daphnopsis malacophylla Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 68. 1944. *J. A. Steyermark 49104*; 18 July 1942; Guatemala, Dept. Huehuetenango, Cerro Cananá, Sierra de los Cuchumatanes; 2,500–2,800 m; F (holo).

Daphnopsis nevlingiana Steyerm., Ann. Missouri Bot. Gard. 74: 653. 1987. *J. A. Steyermark et al. 109199*; 16 18 Feb. 1974; Venezuela, Bolívar, Cerro Sarisariñama, Meseta de Jáua, summit; MO, VEN (holo).

Daphnopsis retifera Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 254. 1940. *J. A. Steyermark 31758*; 13 Nov. 1939; Guatemala, Dept. Jutiapa, between railroad station of Mita and Asunción Mita; 650 m; F (holo) = *D. monocephala* Donn. Sm., 1962.

Schoenobiblus amazonicus Steyerm., Ann. Missouri Bot. Gard. 74: 654. 1987. *G. Wessels-Boer 1953*; 5 Aug. 1967; Venezuela, T. F. Amazonas, 2.5 km S of Puerto Ayacucho; MER (holo), MY.

TILIACEAE

Mortoniodendron Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(2): 157. 1940, gen. nov.

Mortoniodendron guatemalense Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 157. 1940. *W. R. Hatch & C. L. Wilson 54*; 21 July 1936; Guatemala, Dept. Isabal, Río Dulce; F (holo).

Mortoniodendron membranaceum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(3): 158. 1940. *T. G. Yuncker et al. 8519*; 19 July 1938; Honduras, Dept. Atlántida, above Puente Alto stop on S.F. Co. RR, E of La Ceiba; 240 m; F (holo).

TRIGONIACEAE

Trigonia costanensis Steyerm. & Badillo, Acta Bot. Venez. 6: 77. 1971. *A. Madriz 37*; 8 Oct. 1967; Venezuela, Yaracuy, Norte de Nirgua; 1,200 m; MY (holo).

Trigonia rasa Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 59. 1944. *P. C. Standley 78584*; 28 Nov. 1940; Guatemala, Dept. Santa Rosa, Río Panal, Volcán Tecuamburro; F (holo) = *T. eriosperma* (Lamarck) Fromm & Sons subsp. *membranacea* (A. C. Smith) Lleras, 1978.

TURNERACEAE

Erblichia standleyi Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 356. 1940. *T. G. Yuncker et al. 8323*; July 1938; Honduras, Dept. Atlantida, Salado Riva, above Salado, vicinity of La Ceiba; F (holo) = *E. odorata* Seeman, 1979.

Erblichia xylocarpa var. *mollis* Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 355. 1940. *J. A. Steyermark 33448*; Jan. 1940; Guatemala, Dept. Quezaltenango, Quebrada San Gerónimo, Finca Pireneos, Volcán de Santa María; 1,300–2,000 m; F (holo) = *E. odorata* Seeman var. *mollis* (Standl. & Steyerm.) L. O. Williams, 1979.

URTICACEAE

Boehmeria ramiflora Jacq. var. *vinacea* Steyerm., Acta Bot. Venez. 3: 197. 1968. *J. A. & C. Steyermark 95187*; 27–28 Mar. 1966; Venezuela, Carabobo, Río San Gian, Borburato, Planta Electrica, Los Teques, and La Toma; 750 m; VEN (holo).

Pilea killipiana Standl. & Steyerm., Fieldiana Bot. 24(3): 415. 1952. *J. A. Steyermark 44757*; n.d.; Guatemala, Alta Verapaz, along Río Icvolay, N and NW of Finca Cubilquitz to Quebrada Diablo; 250–350 m; F (holo).

Pilea mimema Standl. & Steyerm., Fieldiana Bot. 24(3): 417. 1952. *W. R. Hatch & C. L. Wilson 162*; n.d.; Guatemala, Alta Verapaz, Senahú, Cerro Sillab; F (holo).

Urera killipiana Standl. & Steyerm., Fieldiana Bot. 24(3): 427. 1952. *A. F. Skutch 892*; n.d.; Guatemala, Quezaltenango, Volcán Zunil; F (holo).

VALERIANACEAE

Valeriana delicata Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 255. 1947. *J. A. Steyermark 50936*; 19 Aug. 1942; Guatemala, Dept. Huehuetenango, Cumbre Papal; 1,400–3,000 m; F (holo) = *V. robertianifolia* Briq., 1976.

Valeriana texana Steyerm., Ann. Missouri Bot. Gard. 19: 393. 1932. *J. A. Moore & J. A. Steyermark 3528*; 21 July 1931; U.S.A., Texas, Culberson Co., Guadalupe Mountains, upper McKittrick Canyon; 2,000 m; GH (holo), MO (1011707).

VELLOZIACEAE

Vellozia duidae Steyerm., Fieldiana Bot. 28(1): 157. 1951. *J. A. Steyermark 58270*; 2 Sep. 1944; Venezuela, T.F. Amazonas; Cerro Duida; 1,025–1,200 m; F (holo) = *V. tubiflora* (A. Rich.) H.B.K., 1969.

VERBENACEAE

Aegiphila hoffmannioides Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 227. 1947. *J. A. Steyermark 48843*; 15–16 July 1942; Guatemala, Dept. Huehuetenango, near Maxbal, Sierra de los Cuchumantes; 1,500 m; F (holo) = *Hoffmannia nicotanifolia* (Mart. & Gal.) L. Williams, 1975 in the Rubiaceae not Verbenaceae.

Clerodendron mimicum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(5): 227. 1947. *J. A. Steyermark 48631*; 14 July 1942; Guatemala, Dept. Huehuetenango, Cerro Huitz, Sierra de los Cuchumatanes; 1,500–2,600 m; F (holo) = *Gibsoniothamnus mimicus* (Standl. & Steyerm.) L. Williams, 1974 in the Scrophulariaceae not Verbenaceae.

Clerodendron pithecobium Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(5): 373. 1940. *P. C. Standley 67887*; 8 Mar. 1939; Guatemala, Dept. Quezaltenango, La Shuya, SW of San Martín Chile Verde; 1,620 m; F (holo).

Lantana ruiz-teranii López-Palacios & Steyerm., Ernstia 36: 10. 1986. *L. E. Ruíz Terán & S. López Palacios 10907*; Venezuela, Bolívar, Distr. Roscio, Gran Sabana, Santa Elena de Uairén; 900 m; MER (holo); VEN.

VIOLACEAE

Hybanthus sylvicola Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(4): 176. 1944. *C. L. Wilson 329*; 20 Mar. 1939; Guatemala, Dept. Alta Verapaz, Pilapec, Finca Los Alpes; 270 m; F (holo).

Orthion Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 22(4): 249. 1940, gen. nov.

Rinorea oraria Steyerm. & Fernandez, Brittonia 30: 43. 1978. *G. Morillo et al. 3355*; 17 July 1973; Venezuela, Distr. Federal, Cordillera Costanera, S of Camuri Grande; 700–800 m; COL (holo), VEN.

Viola triloba Schwein f. *albida* Steyerm., Rhodora 54: 256. 1952. *J. A. Steyermark 67440*; 29 Apr. 1949; U.S.A., Missouri, Stone Co., along Route 13, 0.5 mi. NE of Lampe; F (holo).

Viola venezuelensis Steyerm., Fieldiana Bot. 28(2): 403. 1952. *J. A. Steyermark 57077*; 7 July 1944; Venezuela, Mérida, Páramo de la Negra; 2,745–3,045 m; F (holo).

Viola viarum Pollard f. *pilifera* Palmer & Steyerm., Brittonia 10: 116. 1958. *J. A. Steyermark 78500*; 28 Apr. 1955; U.S.A., Missouri, Gentry Co. along branch tributary to ravines on N and E side of Grand River, 1.5–2 mi. S of McFall; F (holo).

VISCACEAE

Phoradendron aguilarii Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 40. 1944. *J. A. Steyermark 31889*; 18 Nov. 1939; Guatemala, Dept. Jutiapa, Vol-

cán Suchitán, NW of Asunción Mita; 1,000–2,050 m; F (holo).

Phoradendron aphyllum Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 412. 1966. *J. A. Steyermark & S. Nilsson 473*; 20 22 Apr. 1960; Venezuela, Bolívar, Cerro Uei; 1,100 m; VEN (holo).

Phoradendron huehuetecum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 41. 1944. *P. C. Standley 82597*; Jan. 1941; Guatemala, Dept. Huehuetenango, near Tachique, E of Huehuetenango; 1,900 m; F (holo).

Phoradendron insigne Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 415. 1966. *J. A. Steyermark & L. Aristeguieta 59*; 9 Mar. 1962; Venezuela, Bolívar, Río Uarama valley below Uarama-tepui; 1,200 m; VEN (holo) = *P. semivenosum* Rizz., 1982.

Phoradendron karuaianum Steyerm., Fieldiana Bot. 28(1): 222. 1951. *J. A. Steyermark 60659*; 27 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,220 m; F (holo).

Phoradendron ptarianum Steyerm., Fieldiana Bot. 28(1): 222. 1951. *J. A. Steyermark 59483*; 29 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 1,810 m; F (holo).

Phoradendron tenuiflorum Steyerm. & Maguire, Mem. New York Bot. Gard. 17(1): 442. 1967. *J. A. Steyermark 75426*; Venezuela, Bolívar, Chimantá-tepui (Toronto-tepui), Chimantá Massif; VEN (holo).

Phoradendron tepuianum Steyerm., Fieldiana Bot. 28(1): 223. 1951. *J. A. Steyermark 59688*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo).

Phoradendron treleaseanum Standl. & Steyerm., Field Mus. Nat. Hist., Bot. Ser. 23(2): 41. 1944. *W. A. Kellerman 7630*; Jan. 1908; Guatemala, Dept. Baja Verapaz, Sierra de las Minas, opposite El Rancho (El Progreso); 700 m; F (holo).

Phoradendron uleanum Steyerm., Fieldiana Bot. 28(1): 223. 1951, nom. nov. = *P. undulatum* (Pohl) Eichl., 1982.

VITACEAE

Cissus venezuelensis Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 427. 1966. *J. A. Steyermark et al. 92987*; 11 Feb. 1964; Venezuela, Bolívar, km 119 and 123 S of El Dorado; 1,030–1,100 m; depository not designated.

VOCHYSIACEAE

Euphronia acuminatissima Steyerm., Ann. Missouri Bot. Gard. 74: 91. 1987. *J. J. Wurdack & L. S. Adderley 43762*; 5 Aug. 1959; Venezuela, T.F. Amazonas, Río Orinoco, Sabana Cumare on right bank of Caño Cumare, Río Atabapo; 125 150 m; MO (holo—2427924); NY.

Qualea apodocarpa Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 473. 1966. *J. A. Steyermark 90467*; 30 Dec. 1961; Venezuela, Bolívar, Río Ichun, debajo del Salto María Espuma; 500 m; VEN (holo) = *Ruizterania apodocarpa* (Steyerm.) Marcano Berti, 1969.

Qualea ferruginea Steyerm., Fieldiana Bot. 28(2): 295. 1952. *J. A. Steyermark 60914*; 11 Dec. 1944; Venezuela, Bolívar, Quebrada de Kavanayen; 1,200–1,220 m; F (holo) = *Ruizterania ferruginea* (Steyerm.) Marcano Berti, 1969.

Qualea rubiginosa Stafleu var. *angustior* Steyerm., Acta Bot. Venez. 2: 239. 1967. *J. A. Steyermark 94203*; 18 May 1964; Venezuela, Bolívar, Auyan-tepui; 1,000 m; VEN (holo) = *Ruizterania rubiginosa* (Stafleu) Marcano Berti var. *angustior* (Steyerm.) Marcano Berti, 1969.

Vochysia pauciflora Steyerm., Bol. Soc. Venez. Ci. Nat. 26: 424. 1966. *J. A. Steyermark et al. 92902*; 9 Jan. 1954; Venezuela, Bolívar, Cerro Venamo; 900 m; VEN (holo).

WINTERACEAE

Drimys brasiliense Miers var. *ptaritepuiensis* Steyerm., Fieldiana Bot. 28(1): 235. 1951. *J. A. Steyermark 59537*; 30 Oct. 1944; Venezuela, Bolívar, Ptari-tepui; 2,100–2,285 m; F (holo).

XYRIDACEAE

Albolboda gleasoniana Steyerm., Fieldiana Bot. 28(4): 820. 1957, nom. nov.

Albolboda macrostachya Spruce var. *robustior* Steyerm., Fieldiana Bot. 28(1): 104. 1951. *J. A. Steyermark 59349*; 26 Oct. 1944; Venezuela, Bolívar, NW to Río Karuai, Gran Sabana; 1,220 m; F (holo).

Albolboda ptaritepuiana Steyerm., Fieldiana Bot. 28(1): 104. 1951. *J. A. Steyermark 59760*; 2 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,000 2,200 m; F (holo) = *Orectanthe ptaritepuiana* (Steyerm.) Maguire, 1958.

Aratitiyopea Steyerm. & Berry, Ann. Missouri Bot. Gard. 71: 297. 1984, gen. nov.

Xyris albescens Steyerm., Fieldiana Bot. 28(1): 105. 1951. *J. A. Steyermark 59734*; 2 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,000 2,200 m; F (holo).

Xyris capillaris Steyerm., Fieldiana Bot. 28(1): 107. 1951. *J. A. Steyermark 57835*; 22 Aug. 1944; Venezuela, T.F. Amazonas, between Esmeralda Savanna and SE base of Cerro Duida; 200 m; F (holo).

Xyris culmenicola Steyerm., Fieldiana Bot. 28(1): 108. 1951. *J. A. Steyermark 58233*; 2 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida, Brocchinia Hills; 1,700–1,980 m; F (holo).

Xyris esmeraldae Steyerm., Fieldiana Bot. 28(1): 109. 1951. *J. A. Steyermark 57821*; 22 Aug. 1944; Venezuela, T. F. Amazonas, between Esmeralda Savanna and SE base of Cerro Duida; 200 m; F (holo).

Xyris jauana L. B. Smith & Steyerm., Bol. Soc. Venez. Ci. Nat. 32: 277. 1976. *J. A. Steyermark et al. 109390*; 22–28 Feb. 1974; Venezuela, Bolívar, Meseta del Jaua, Cerro Jaua; 1,750–1,800 m; depository not designated.

Xyris lanulobractea Steyerm., Fieldiana Bot. 28(1): 109. 1951. *J. A. Steyermark 59336*; 26 Oct. 1944; Venezuela, Bolívar, Gran Sabana; 1,220 m; F (holo).

Xyris ptariana Steyerm., Fieldiana Bot. 28(1): 110. 1951. *J. A. Steyermark 59919*; 7 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 2,410–2,450 m; F (holo).

Xyris scabridula Steyerm., Fieldiana Bot. 28(1): 111. 1951. *J. A. Steyermark 58168*; 1 Sep. 1944; Venezuela, T.F. Amazonas, Cerro Duida, Brocchinia Hills; 1,700–1,980 m; F (holo).

Xyris schneeana Smith & Steyerm., Acta Bot. Venez. 2: 149. 1967. *L. Schnee 1577*; 19 Apr. 1956; Venezuela, Bolívar, Auyan-tepui; MY (holo).

Xyris setigera Oliver var. *elongata* Steyerm., Fieldiana Bot. 28(1): 112. 1951. *J. A. Steyermark 59660*; 1 Nov. 1944; Venezuela, Bolívar, Ptari-tepui; 1,600 m; F (holo).

Xyris stenostachya Steyerm., Fieldiana Bot. 28(1): 113. 1951. *J. A. Steyermark 58437*; 8 Sep. 1944; Venezuela, T.F. Amazonas, below mouth of Río Sanariapo, along Orinoco River; 100 m; F (holo).

ZINGIBERACEAE

Costus zamoranus Steyerm., Phytologia 9(6): 339. 1964. *J. A. Steyermark 54664*; 14 Oct. 1943; Ecuador, Santiago-Zamora, along Río Valladolid, around Tambo Valladolid; 2,000 m; F (holo), NY, US.

Renealmia puberula Steyerm., Phytologia 9(6): 340. 1964. *J. A. Steyermark 54901*; 6 Nov. 1943; Ecuador, Prov. Napo-Pastaza, along Río Pastaza below Finca Black; 1,212 m; F (holo), MO, NY.

Renealmia stellulata Steyerm., Phytologia 9(6): 341. 1964. *J. A. Steyermark 53769*; 11 Aug. 1943; Ecuador, Prov. El Oro, along tributary to Río Palma, near Pampa do los Cedros S of Cerro Chivo-turco; 2,135 2,285 m; F (holo), NY.

Appendix I

Eponymy. Plants named in honor of Julian Steyermark. These are all the names found while examining the literature cited in the bibliography. It is not a complete list. Additions or corrections would be most welcome.

TRIBES		
Steyermarkochloeae Davidse & Ellis		Poaceae
GENERA		
Aristeyera H. Moore = *Asterogyne* H. Wendle		Arecaceae
Jasarum Bunting		Araceae
Steyerbromelia L. B. Smith		Bromeliaceae
Steyermarkia Standl.		Rubiaceae
Steyermarkiella H. Robinson		Musci
Steyermarkina R. M. King & H. Robinson		Asteraceae
Steyermarkochloa Davidse & Ellis		Poaceae
SPECIES	TYPE	
Abuta steyermarkii (Standl.) Standl.		Menispermaceae
Achnopogon steyermarkii Aristeg.	*Steyermark 93512*	Asteraceae
Aegiphila steyermarkii Mold.	*Steyermark 59960*	Verbenaceae
Amanoa steyermarkii Jabl.	*Steyermark 93238*	Euphorbiaceae
Anomospermum steyermarkii Krukoff & Barneby	*Frões 21466*	Menispermaceae
Anthurium julianii Bunting	*Steyermark 97325*	Araceae
Anthurium steyermarkii Bunting	*Steyermark 74850*	Araceae
Aphanocarpus steyermarkii (Standl.) Steyerm.		Rubiaceae
Aristolochia steyermarkii Standl. = *Aristolochia arborea* J. Linden, 1966	*Steyermark 33455*	Aristolochiaceae
Arthrostylidium steyermarkii McClure	*Steyermark 59926*	Poaceae
Asketanthera steyermarkii Markgraf	*Steyermark 99348*	Apocynaceae
Aspidosperma steyermarkii Woodson	*Steyermark 59858*	Apocynaceae
Axonopus steyermarkii Swallen	*Steyermark 58001*	Poaceae
Azorella julianii Math. & Const.	*Steyermark 55894*	Apiaceae
Befaria steyermarkii A. C. Smith	*Steyermark 62711*	Ericaceae
Begonia steyermarkii L. B. Smith & B. G. Schubert	*Steyermark 75502*	Begoniaceae
Beloperone steyermarkii Leonard	*Steyermark 56869*	Acanthaceae
Besleria steyermarkiorum Wiehler	*Steyermark 111182*	Gesneriaceae
Bidens steyermarkii Sherff	*Steyermark 50998*	Asteraceae
Blepharodon julianii Morillo	*Steyermark 111304*	Asclepiadaceae
Blepharodon steyermarkii R. Holm	*Steyermark 60813*	Asclepiadaceae
Bonnetia steyermarkii Kobuski	*Steyermark 59570*	Theaceae
Bouvardia steyermarkii Standl.	*Steyermark 29671*	Rubiaceae
Brachionidium julianii Carnevali & Ramirez	*Steyermark 129512*	Orchidaceae
Brachionidium steyermarkii Foldats	*Steyermark 98592*	Orchidaceae
Brocchinia steyermarkii L. B. Smith	*Steyermark 60347*	Bromeliaceae
Bulbophyllum steyermarkii Foldats	*Steyermark 100818*	Orchidaceae
Bursera steyermarkii Standl.	*Steyermark 30068*	Burseraceae
Byrsonima steyermarkii Anderson	*Steyermark 97979*	Malpighiaceae
Caladium steyermarkii Bunting	*Steyermark 102035*	Araceae
Calceolaria steyermarkii Pennell = *Calceolaria fusca* Pennell, 1988	*Steyermark 54475*	Scrophulariaceae
Campylocentrum steyermarkii Foldats	*Steyermark 96715*	Orchidaceae
Capparis steyermarkii Standl.	*Steyermark 39387*	Capparidaceae
Carex steyermarkii Standl.	*Steyermark 48542*	Cyperaceae
Castilleja steyermarkii Pennell	*Steyermark 57137*	Scrophulariaceae
Cecropia steyermarkii Cuatr.	*Steyermark 109842*	Cecropiaceae
Cephalocarpus steyermarkii Gilly	*Steyermark 56940*	Cyperaceae
Chiococca steyermarkii Standl.	*Steyermark 36237*	Rubiaceae
Chrysophyllum steyermarkii Monachino	*Steyermark 57717*	Sapotaceae
Citharexylum steyermarkii Mold.	*Steyermark 31433*	Verbenaceae
Cladium steyermarkii T. Koyama = *Rhynchocladium steyermarkii* (T. Koyama) T. Koyama, 1972	*Steyermark & Wurdack 1225*	Cyperaceae
Clidemia steyermarkii Wurd.	*Steyermark 96653*	Melastomataceae
Clitoria steyermarkii Fantz	ined.	Fabaceae
Clusia steyermarkii Maguire	*Steyermark 75977*	Clusiaceae
Cobaea steyermarkii Standl.	*Steyermark 37759*	Polemoniaceae
Coccoloba steyermarkii Standl.	*Steyermark 39533*	Polygonaceae
Columnea steyermarkii Morton	*Steyermark & Nilsson 41*	Gesneriaceae

Connarus steyermarkii Prance	*Steyermark 91995*	Connaraceae
Conomorpha steyermarkiana Agost. = *Cybianthus steyermarkianus* (Agost.) Agost., 1988	*Cardona Puig 2723*	Myrsinaceae
Cosmos steyermarkii Sherff	*Steyermark 31341*	Asteraceae
Cottendorfia steyermarkii (L. B. Smith) L. B. Smith		Bromeliaceae
Couepia steyermarkii Maguire	*Steyermark 60025*	Chrysobalanaceae
Coussapoa steyermarkii Cuatr.	*Steyermark 60002a*	Urticaceae
Crumenaria steyermarkii Standl.	*Steyermark 30448*	Rhamnaceae
Cuchumatanea steyermarkii Seidensch. & Beaman	*Beaman 3962*	Asteraceae
Cyathea steyermarkii Tryon	*Steyermark 105194*	Cyatheaceae
Cybianthus steyermarkianus (Agost.) Agost.		Myrsinaceae
Cyclanthera steyermarkii Standl.	*Steyermark 34047*	Cucurbitaceae
Cynanchum julianii Morillo	*Morillo 10102*	Asclepiadaceae
Dacryodes steyermarkii Sandw.	*Steyermark 92354*	Burseraceae
Dahlia coccinea var. *steyermarkii* Sherff	*Steyermark 50341*	Asteraceae
Daphnopsis steyermarkii Nevling	*Steyermark & Wurdack 781*	Thymelaeaceae
Davilla steyermarkii Kubitzki	*Steyermark 117841*	Dilleniaceae
Dendrophthora steyermarkii Rizz. = *Dendrophthora squamigera* (Benth.) O. Kuntze, 1982	*Steyermark 98573*	Loranthaceae
Diacidium steyermarkii (Maguire) Anderson		Malpighiaceae
Dicella julianii (Macbr.) Anderson		Malpighiaceae
Dichapetalum steyermarkii Prance	*Steyermark 89875*	Dichapetalaceae
Dicranoloma steyermarkii Bartr.	*Steyermark 74980b*	Musci
Dioclea steyermarkii R. H. Maxwell	ined.	Fabaceae
Distictis steyermarkii Gentry	*Steyermark 105274*	Bignoniaceae
Duranta steyermarkii Mold.	*Steyermark 62102*	Verbenaceae
Echeveria steyermarkii Standl.	*Steyermark 43145*	Crassulaceae
Elaphoglossum steyermarkii Mickel	*Steyermark 128500*	Aspleniaceae
Elleanthus steyermarkii Barringer	*Steyermark 54873*	Orchidaceae
Elvasia steyermarkii Maguire	*Steyermark 96342*	Ochnaceae
Epidendrum steyermarkii A. D. Hawkes	*Moritz 1065*	Orchidaceae
Epiphyllum steyermarkii Croizat	*Steyermark 108741*	Cactaceae
Eriocaulon steyermarkii Mold.	*Steyermark 58868*	Eriocaulaceae
Eriosorus paucifolius var. *steyermarkii* A. F. Tryon	*Steyermark 59913*	Adiantaceae
Erythroxylum steyermarkii Plowman	*Steyermark 107840*	Erythroxylaceae
Espeletia steyermarkii Cuatr. = *E. brassicoidea* var. *contracta* Cuatr., 1964	*Steyermark 57217*	Asteraceae
Eugenia steyermarkii Standl.	*Steyermark 36210*	Myrtaceae
Eupatorium steyermarkianum Badillo	*Steyermark 56795*	Asteraceae
Euphorbia steyermarkii Standl.	*Standley 74673*	Euphorbiaceae
Everardia steyermarkii Gilly	*Steyermark 59781*	Cyperaceae
Exochogyne steyermarkii Gilly	*Steyermark 57820*	Cyperaceae
Fissidens steyermarkii Bartr.	*Steyermark 36576*	Musci
Freziera steyermarkii Kobuski	*Steyermark 61443*	Theaceae
Gomphicus steyermarkii Foldats	*Steyermark 100883*	Orchidaceae
Gonolobus steyermarkii Woodson	*Steyermark 37661*	Asclepiadaceae
Graffenrieda steyermarkii Wurd.	*Steyermark 74883*	Melastomataceae
Greigia steyermarkii L. B. Smith	*Steyermark 42553*	Bromeliaceae
Guettarda steyermarkii Standl.	*Steyermark 56601*	Rubiaceae
Guzmania steyermarkii L. B. Smith	*Steyermark & Nilsson 428*	Bromeliaceae
Helianthostylis steyermarkii C. C. Berg	*Steyermark 102860*	Moraceae
Heliconia julianii Barreiros	*Steyermark 102678*	Heliconiaceae
Henriettella steyermarkii Wurd.	*Steyermark 90647*	Melastomataceae
Heteropsis steyermarkii Bunting	*Steyermark 102607*	Araceae
Heteropterys steyermarkii Anderson	*Steyermark 105009*	Malpighiaceae
Hexapterella steyermarkii Maas & Maas	*Liesner 22622*	Burmanniaceae
Hidalgoa steyermarkii Sherff	*Steyermark 48814*	Asteraceae
Hoffmannia steyermarkii Steyerm. = *H. rotata* J. D. Smith, 1975	*Steyermark 36426*	Rubiaceae
Hookeriopsis steyermarkii Bartr.	*Steyermark 59942*	Musci
Hydrangea steyermarkii Standl.	*Steyermark 36044*	Saxifragaceae
Hydrocotyle steyermarkii Math. & Const.	*Steyermark 54566*	Apiaceae
Hymenophyllopsis steyermarkii Vareshi	*Steyermark 75644*	Hymenophyllopsidaceae
Hyperbaena steyermarkii Standl. = *Abuta steyermarkii* (Standl.) Standl., 1944	*Steyermark 39454*	Menispermaceae
Hypericum steyermarkii Standl.	*Steyermark 34760*	Clusiaceae
Ilex julianii Edwin	*Steyermark 91538*	Aquifoliaceae
Ilex steyermarkii Edwin	*Steyermark 75501*	Aquifoliaceae

Jasarum steyermarkii Bunting	*Steyermark 105500*	Araceae
Juglans steyermarkii Manning	*Steyermark 51140*	Juglandaceae
Justicia steyermarkii Standl. & Steyerm.	*Steyermark 48934*	Acanthaceae
Lagenocarpus steyermarkii Gilly	*Steyermark 59363*	Cyperaceae
Leandra steyermarkii Wurd.	*Steyermark 102757*	Melastomataceae
Ledothamnus steyermarkii A. C. Smith	*Steyermark 59484*	Ericaceae
Leothrix steyermarkii Mold.	*Steyermark 59779*	Eriocaulaceae
Lepanthes steyermarkii Foldats	*Steyermark 98381*	Orchidaceae
Lepanthopsis steyermarkii Foldats	*Steyermark 99218*	Orchidaceae
Lepidopilum steyermarkii Bartr.	*Steyermark 56138*	Musci
Licania steyermarkii Maguire	*Steyermark 60768*	Chrysobalanaceae
Lindmania steyermarkii L. B. Smith	*Steyermark & Wurdack 827*	Bromeliaceae
Lycopodium steyermarkii Ollgaard, ined.	*Steyermark 97895*	Lycopodiaceae
Lysimachia steyermarkii Standl.	*Steyermark 34772*	Primulaceae
Macrocentrum steyermarkii Wurd.	*Maguire et al. 53864*	Melastomataceae
Macrolobium steyermarkii Cowan	*Steyermark 90939*	Fabaceae
Malaxis steyermarkii Correll	*Steyermark 51672*	Orchidaceae
Mandevilla steyermarkii Woodson	*Steyermark 58504*	Apocynaceae
Mapania steyermarkii T. Koyama	*Koyama 7506*	Cyperaceae
Marcgravia steyermarkii de Roon	*Steyermark 108921*	Marcgraviaceae
Marsdenia steyermarkii Woodson	*Steyermark 36019*	Asclepiadaceae
Matelea steyermarkii Woodson	*Steyermark 35810*	Asclepiadaceae
Maxillaria steyermarkii Foldats	*Steyermark 98384*	Orchidaceae
Meriania steyermarkii Gleason	*Steyermark 56513*	Melastomataceae
Miconia steyermarkii Gleason	*Steyermark 58262*	Melastomataceae
Microlicia steyermarkii Gleason = *Microlicia benthamiana* Triana ex Cogn., 1973	*Steyermark 59331*	Melastomataceae
Micropholis steyermarkii Monachino	*Steyermark 60650*	Sapotaceae
Monstera steyermarkii Bunting	*Bunting 4805*	Araceae
Mouriri steyermarkii Standl.	*Steyermark 39446*	Melastomataceae
Myrcia exploratoris McVaugh; dedicated to Dr. Julian Steyermark	*Steyermark 60879*	Myrtaceae
Myriocladus steyermarkii Swallen	*Steyermark & Wurdack 819*	Poaceae
Navia steyermarkii L. B. Smith	*Steyermark 58012*	Bromeliaceae
Nothochlaena steyermarkii Vareschi	*Steyermark 75534*	Polypodiaceae
Ocotea julianii van der Werff	*Steyermark & Wurdack 921*	Lauraceae
Ocotea steyermarkiana C. K. Allen	*Steyermark 93476*	Lauraceae
Octomeria steyermarkii Garay & Dunsterville	*Dunsterville 833*	Orchidaceae
Odontocarya steyermarkii Barneby	*Steyermark 101939*	Menispermaceae
Odontonema steyermarkii Leonard	*Steyermark 35020*	Orchidaceae
Oncidium steyermarkii Foldats	*Steyermark 96993*	Orchidaceae
Ophellantha steyermarkii Standl.	*Steyermark 51398*	Euphorbiaceae
Oreopanax steyermarkii A. C. Smith	*Steyermark 42649*	Araliaceae
Ormosia steyermarkii Rudd	*Steyermark 60503*	Fabaceae
Ouratea steyermarkii Sastre	*Steyermark 112797*	Ochnaceae
Oxythece steyermarkiana Monachino	*Steyermark 603321*	Sapotaceae
Oyedaea steyermarkii Blake	*Steyermark 45686*	Asteraceae
Pachyphyllum steyermarkii Foldats	*Steyermark 98345*	Orchidaceae
Paepalanthus perplexans var. *steyermarkii* Mold.	*Steyermark 115640*	Eriocaulaceae
Paepalanthus steyermarkii Mold.	*Steyermark 59369*	Eriocaulaceae
Pagamea steyermarkii Standl. = *Aphanocarpus steyermarkii* (Standl.) Steyerm., 1965, 1967	*Steyermark 59744*	Rubiaceae
Panicum steyermarkii Swallen	*Steyermark & Wurdack 954*	Poaceae
Parabignonia steyermarkii Sandw.	*Steyermark 93003*	Bignoniaceae
Peperomia steyermarkii Yuncker	*Steyermark 61874*	Piperaceae
Perissocarpa steyermarkii (Maguire) Steyerm. & Maguire		Ochnaceae
Persea steyermarkii C. K. Allen	*Steyermark 37061*	Lauraceae
Phainantha steyermarkii Wurdack	*Steyermark 108984*	Melastomataceae
Philacra steyermarkii Maguire	*Steyermark 93844*	Ochnaceae
Philodendron steyermarkii Bunting	*Steyermark 102603*	Araceae
Phoebe steyermarkiana C. K. Allen = *Ocotea julianii* van der Werff	*Steyermark & Wurdack 921*	Lauraceae
Phoradendron steyermarkii Rizz.	*Steyermark 115564*	Viscaceae
Phthirusa steyermarkiana Rizz.	*Steyermark 112735*	Loranthaceae
Piper steyermarkii Yuncker	*Steyermark 59996*	Piperaceae

Serjania steyermarkii	Sapindaceae

Appendix II

Collectors Index. This cross-reference is arranged alphabetically by the collectors' last names; these are followed by initials and full name in parentheses. Then appear sequential listing of collection numbers with taxa and author. Taxa listed in Appendix I are included. Collector eponymy is shown with italics. A few duplicate numbers, resulting from manuscript names or possible errors, are also italicized. Most co-collectors have been omitted except when they collected under separate number series.

COLLECTORS NOT GIVEN

s.n. Orthrosanthus chimboracensis var. intermedius Steyerm.
s.n. Ravnia panamensis Steyerm.

ABRAMS, L. R. (LeRoy)

3957 Grindelia hallii Steyerm.

ACOSTA SOLIS, M.

5054 Clethra rugosa Steyerm.
7008 Siparuna rugosa Steyerm.
7009 Markea grandiflora Steyerm.
7743 Cyphomandra villosa Steyerm.
8233 Siparuna verrucosa Steyerm.

ADAMS, W. (Wayne)

s.n. Trillium recurvatum Beck f. foliosum Steyerm.
s.n. Trillium recurvatum Beck f. petaloideum Steyerm.

AGOSTINI, G. (Getulio)

30 Psychotria guadalupensis subsp. venezuelica Steyerm.
84 Maytenus *agostinii* Steyerm.
1120 Piper *agostiniorum* Steyerm.

AGUILAR, J. I. (José Ignacio)

810 Calyptranthes *aguilarii* Standl. & Steyerm.
1757 Eugenia rheedioides Standl. & Steyerm.

ALLART, A.

225 Gonzalagunia dicocca subsp. venezuelenesis Steverm.

ALLEN, P. H. (Paul Hamilton)

2153 Stegolepis *allenii* Steyerm.
2240 Voyria *allenii* Steyerm.
3560 Chimarrhis decurrens Steverm.
4576 Coussarea darienensis Steyerm.
4744 Ravnia longifilamentosa Steyerm.

ALSTON, A. H. G. (Arthur Hugh Garfit)

6167 Piper arieianum var. yaracuyense f. nubicolum Steyerm.
6533 Galium canescens f. *alstonii* Steyerm.

ANDERSON, W. R. (William)

35874 Perama irwiniana Kirkbr. & Steyerm.

ARISTEGUIETA, L. (Léandro)

555 Emmeorrhiza umbellata subsp. septentrionalis var. pubens Steyerm.
1649 Sabicea *aristeguietae* Steyerm.
1824 Sickingia *aristeguietae* Steyerm.
1924 Peperomia aroensis Steyerm.
1948 Peperomia pseudoglabella Steyerm.
1952 Psychotria aroensis Steyerm.
1989 Elaegia magniflora Steyerm.
2149 Rondeletia *aristeguietae* Steyerm.
2295 Ilex glaucophylla Steverm.
3036 Dacryodes costanensis Steyerm.
3938 Rudgea sanarensis Steyerm.
4193 Randia *aristeguietae* Steyerm.
4250 Borreria capitata f. glabra Steyerm.
5264 Alibertia acuminata var. obtusiuscula Steyerm.
5343 Randia brevipes Steyerm. (pistillate)
6466 Borojoa universitatis Steyerm.
7129 Psychotria patria var tovarensis Steyerm.

AYMARD, G. (Gerardo)

4631 Zinowiewia *aymardii* Steyerm.

BADILLO, V. M. (Victor)

3126 Manettia *badilloi* Steyerm.
4866 Gunnera pittieriana Badillo & Steyerm.

BALDWIN, J. T., JR.

4077 Utricularia *baldwinii* Steyerm.

BARNES, V.

43 Styrax longipedicellatus Steyerm.

BARRETO

1134 Perama sparsiflora Standl., Steyerm. & Kirkbr.

BARTEL, K. E.

s.n. Liatris cylindracea f. *bartelli* Steyerm.
1 Dipsacus sylvestris Huds. f. albidus Steyerm.

BARTLETT, H. H. (Harley Harris)

8300 Diodia hyssopifolia var. linearis f. glabriuscula Steyerm.

BAUER, B.

s.n. Ruellia pedunculata f. *baueri* Steyerm.

BAUTISTA, J. A. (John Louis)

5037 Peperomia glabella var. obtusa Steyerm.

BEAMAN

3962 Cuchumatanea steyermarkii Seidensch. & Beaman

BELEM, R. P.

2738 Sphinctanthus insignis Steyerm.

BERLANDIER, J. L. (John Louis)

766 (2186) Grindelia tenella Steyerm.

BERNARDI, A. L.

3180 Hoffmannia *bernardii* Steyerm.
5829a Tresanthera thyrsiflora Steyerm.

BERNARDI, L. (Luciano)

611 Manettia *bernardii* Steyerm.
985 Arachnothrix reflexa var. meridensis Steyerm.
1248 Manettia paramorum Steyerm.
1296 Psychotria costanensis subsp. andina Steyerm.
1304 Psychotria *bernardii* Steyerm.
1690 Pagamea plicata var. multinervia Steyerm.
1720 Psychotria trichotoma var. trichophylla Steyerm.
2011 Guettarda *bernardii* Steyerm.
2325 Coussarea *bernardii* Steyerm.
6746 Neea *bernardii* Steyerm.
7437 Palicourea buntingii var. glabrior Steyerm.

BERRY, P. E. (Paul)

694 Piper otto-huberi var. eciliatum Steyerm.
1558 Rudgea *berryi* Steyerm. & Dwyer
2096 Faramea *berryi* Steyerm.
2116 Remija *berryi* Steyerm.
2152 Ouratea macurucoensis Maguire & Steyerm.
3670 Eugenia mcvaughii Steyerm. & Lasser
3825 Piper *berryi* Steyerm.
3923 Pereromia *berryi* Steyerm.

BLANCO, C. (Carlos)

1158 Guapira sipapoana Steyerm.

BLANKINSHIP, J. W. (Joseph William)

s.n. Grindelia nana var. altissima f. puberula Steyerm.

BLYDENSTEIN, J.

250 Diodia teres subsp. prostrata f. latifolia Steyerm.

BOLANDER, H. N. (Harry Nicholas)

389 Grindelia hirsutula f. cacumena Steyerm.

BONO, J. (José)

3797 Hillia *bonoi* Steyerm.

BOOM, B. (Brian)

5274 Ferdinandusa *boomii* Steyerm.
5278 Faramea *boomii* Steyerm.
6417 Peperomia *boomii* Steyerm.

BORDENER, V. (Valerie)

s.n. Podophyllum peltatum f. biltmoreanum Steyerm.

BRADE

4739 Perama sparsiflora Standl., Steyerm. & Kirkbr.

BRANDEGEE, K. (Katherine, or Mary Katherine Curran nee Layne)

s.n. Grindelia rubricaulis var. latifolia f. pubescens Steyerm.

BRAUN, E. L. (Lucy)

s.n. Silphium terebinthinaceum var. *lucy-brauniae* Steyerm.

BRETELER, F.

3463 Hoffmannia pauciflora subsp. venezuelensis Steyerm.
4082 Piper veraguense var. venezuelense Steyerm.
4089 Manettia *breteleri* Steyerm.
4095 Diodia radula subsp. venezuelensis Steyerm.
4204 Diodia teres subsp. prostrata f. leiocarpa Steyerm.
4832 Ouratea inconformis Maguire & Steyerm.

BREWER, C., JR.

248 Navia *breweri* L. B. Smith & Steyerm.

BRINKLEY

250 Echinacea purpurea var. arkansana Steyerm.
268 Clematis versicolor f. pubescens Steyerm.

BRITTON, N. L. (Nathaniel Lord)

2104 Psychotria capitata subsp. inundata var. septentrionalis Steyerm.
2684 Randia brevipes Steyerm. (staminate)
2702 Randia aculeata f. minor Steyerm.

BROADWAY, W. E.

9823 Psychotria muscosa subsp. breviloba Steyerm.

BUCHTIEN, O. (Otto)

1719 Faramea anisocalyx var. schwackei f. dentata Steyerm.

BUNTING, G. S. (George)

2332 Piper deliciasanum Steyerm.
4461 Peperomia choroniana var. heterodoxa Steyerm.
4509 Ladenbergia *buntingii* Steyerm.
4805 Monstera steyermarkii Bunting
10876 Pyschotria *buntingii* Steyerm.

BUSH, B. F. (Benjamin)

7041 Diospyros virginiana f. pumila Palmer & Steyerm.
10332 Corylus americana f. indehiscens Palmer & Steyerm.

CÁRDENAS DE GUAVARA, L. (Lourdes)

805 Arachnothris rugulosa var. tachirensis Steyerm.

CARDONA P., F. (or F. Cardona Puig) (Felix)

309b Pagameopsis maguirei subsp. pusillus var. glabrus Steyerm.

707 Sabicea venezuelensis Steyerm.
819 Duroia bolivarensis Steyerm.
860 Platycarpum rhododactylum Woodson & Steyerm.
1051 Sloanea merevariensis Pittier ex Steyerm.
1115 Faramea *cardonae* Standl. & Steyerm.
1117 Malanea guaiquinimensis Steyerm.
1333 Psychotria parimensis Steyerm.
1383 Palicourea *cardonae* Steyerm.
1480 Ilex *cardonae* Steyerm.
1496 Psychotria tapirapecoana Steyerm.
1503 Rudgea *cardonae* Steyerm.
1610 Gleasonia duidana var. oblanceolata Steyerm.
1630 Perama glalioides var. densipila Steyerm.
2190 Stenopadus taloumifolius var. magnifolius Steyerm.
2204 Ouratea ramosissima Maguire & Steyerm.
2288 Quelchia *cardonae* Steyerm.
2661 Heliamphora minor f. laevis Steyerm.
2723 Conomorpha steyermarkiana Agost.
2943 Ilex magnifructa var. minor Steyerm.
2967 Psychotria phaneroloma var. angustior Steyerm.

CARLSON, M. C.

1744 Ardisia *carlsonae* Steyerm.

CARNEVALI, G. (Germán)

640 Peperomia *carnevalii* Steyerm.

CASTELLANOS, E.

46 Borreria aristeguietaeana Steyerm.

CAVALCANTE, P.

712 Retiniphyllum longiflorum Steyerm.
2511 Randia pubiflora Steyerm.

CHARDÓN PALACIOS, C. E. (Carlos Eugenio)

179 Arachnothrix venezuelensis Steyerm.

CLARK, H. L. (Howard)

6742 Catostemma pubistylum Steyerm.
6980 Neea *clarkii* Steyerm.
7794 Guapira sancarlosiana Steyerm.
8111 Schoepfia *clarkii* Steyerm.
8117 Catostemma sancarlosiana Steyerm.
8126 Catostemma *clarkii* Steyerm.

CONGDON, J. W.

s.n. Grindelia aggregata Steyerm.

CONICIT, E.

2663 Piper bredemeyeri f. escabridum Steyerm.

COOPER, G. P.

586 Bertiera aequaliramosa Steyerm.

CORE

1367 Joosia umbellifera var. caucana Steyerm.

COWAN, R. S. (Richard Sumner)

1863 Sipanea *cowanii* Steyerm.
1897 Psychotria hoffmannseggiana f. pubescens Steyerm.
31061 Orthaea paruensis Maguire, Steyerm. & Luteyn
31104 Ouratea paruensis Maguire & Steyerm.
31130 Chondrococcus laevis Steyerm.
31241 Pagamea diceras Steyerm.
31378 Roupala paruensis Steyerm.
31388 Rhamnus longipes Steyerm.
31405 Schefflera guanayensis subsp. paruensis Maguire, Steyerm. & Frodin
31447 Duroia paruensis Steyerm.
31450 Matayba longipes subsp. tepuiensis Steyerm.
31455 Perama galioides f. macrocephala Steyerm.
31462 Ouratea brevicalyx Maguire & Steyerm.
31473 Platycarpum orinocense var. grandiflorum Steyerm.
38429 Rudgea bremekampiana Steyerm.
39036 Rudgea standleyana Steyerm.

CREMERS, G.

6460 Sipanea ovalifolia var. villosissima Steyerm.

CROAT, T. B. (Thomas)

6647 Geophila *croatii* Steyerm.
54112 Coccocypselum *croatii* Steyerm.
54158a Ilex gransabanensis Steyerm.
59478 Ilex abscondita Steyerm.

CROIZAT, L. (Léon Camille Marius)

624 Ouratea *croizatii* Maguire & Steyerm.

CRUEGER

s.n. Psychotria perpapillifera Steyerm.

CUATRECASAS, J. (José)

9198 Tocoyena *cuatrecasasii* Steyerm.
11515 Elaeagia multinervia Steyerm.
13694 Cuatrecasasiodendron colombianum Steyerm.
14827 Joosia umbellifera var. occidentalis Steyerm.
15182 Schradera puberula Steyerm.
15192 Dioicodendron *cuatrecasasii* Steyerm.
17165 Cuatrecasasiodendron spectabile Steyerm.
21086 Schradera pulverulenta Steyerm.
21682 Elaeagia *cuatrecasasii* Steyerm.
23870 Elaeagia alterniramosa Steyerm.
24332 Arachnothrix reflexa var. calycina Steyerm.

CURRAN, H.

s.n. Faramea occidentalis var. brachycalyx Steyerm.

CUTLER, H. C. (Hugh Carson)

8363 Utricularia *cutleri* Steyerm.
8365 Utricularia cearana Steyerm.

DAVIDSE, G. (Gerrit)

12910 Alibertia *davidsei* Steyerm.
15825 Coccocypselum apurense Steyerm.
16382 Guapira *davidsei* Steyerm.
16558 Neea *davidsei* Steyerm.
17011 Matayba affinis Steyerm.
17359 Palicourea huberi Steyerm.

17427 Botryarrhena venezuelensis Steyerm.
22679 Ilex polita Steyerm.
22719 Ilex *davidsei* Steyerm.
27327 Morinda longipedunculata Steyerm.
27651 Psychotria anartiothrix Steyerm.
27719 Ilex *davidsei* Steyerm.
27733 Sloanea *davidsei* Steyerm.

DAVIDSON, A. (Anstruther)

736 (96) Grindelia arizonica var. microphylla Steyerm.

DAVIDSON, M. E.

892 Croton standleyi Steyerm.

DAWSON, E. Y. (Yale)

14163a Declieuxia dasyphylla f. ciliata Steyerm.
14594 Euphorbia machrisiae Steyerm.
14672 Diodia angustata Steyerm.
14685 Croton inaequilobus Steyerm.
14770 Utricularia *dawsonii* Steyerm.
14776 Phyllanthus *dawsonii* Steyerm.
14918 Phyllanthus websterianus Steyerm.
14973 Croton douradensis Steyerm.

DE GRANVILLE, J. J. (Jacques)

C.159 Psychotria antenniformis Steyerm.
2353 Psychotria *granvillei* Steyerm.
2360 Psychotria lateralis Steyerm.
2361 Psychotria saulensis Steyerm.
2362 Psychotria microbracteata Steyerm.
2383 Psychotria galbaoensis Steyerm.
2393 Psychotria urceolata Steyerm.
2793 Psychotria viridibractea Steyerm.
3127 Psychotria alloantha Steyerm.
B.4640 Psychotria perferruginea Steyerm.
B.5288 Psychotria squamelligera Steyerm.

DE LA CRUZ, J. S.

1638 Palicourea guianensis subsp. occidentalis Steyerm.
2164 Malanea *cruzii* Steyerm.

DE LA RUE, A.

13 Psychotria capitata subsp. amplifolia f. tomentosa Steyerm.

DE LEMOS FRÓES, R. (Ricardo) see Fróes, R. L.

DEAM, C. C. (Charles Clemon)

40 Mikania guatemalensis Standl. & Steyerm.

DELASCIO CHITTY, F. (Francisco)

8471 Chomelia *delascioi* Steyerm.
12358 Perama dichotoma var. monocephala Steyerm.
13161 Peperomia *delascioi* Steyerm.

DELGADO, E.

160 Tocoyena costanensis Steyerm.
233 Linociera avilensis Steyerm.

DUCKE, A. (Adolpho)

81 Henriquezia verticillata var. apiculata Steyerm.
522 Burdachia *duckei* Steyerm.
683 Pagamea coriacea var. pubescens Steyerm.
799 Duroia nitida Steyerm.
1005 Platycarpum *duckei* Steyerm.
1141 Borojoa *duckei* Steyerm.
1167 Ferdinandusa *duckei* Steyerm.
1332 Duroia eriopila var. brevidentata Steyerm.
1557 Kotchubaea *duckei* Steyerm.
1844 Stachyarrhena acutiloba Steyerm.
1943 Malanea subtruncata Steyerm.
8462 Pagamea puberula Steyerm. (RB 22951)

DUDLEY, T. R.

13089 Psychotria *dudleyi* Steyerm.
13543 Pagamea *dudleyi* Steyerm.

DUNSTERVILLE, G. C. K. (Geoffrey)

833 Octomeria steyermarkii Garay & Dunsterville

DUQUE, J. M.

1559 Elaeagia barbata Steyerm.

EASTWOOD, A. (Alice)

s.n. Grindelia hirsutula var. brevisquama f. pedunculoides Steyerm.
794 Grindelia rubricaulis var. latifolia f. minor Steyerm.

EGLER, W. A.

46683 Hillia irwinii Steyerm.
47729 Malanea *egleri* Steyerm.

EHRENDORFER, F. (Friedrich)

74104-23 Talisia pentantha Steyerm.

EKMAN, E. L. (Erik Leonard)

9368 Schradera cubensis Steyerm.

ESPINOSA, R.

1076 Nierembergia *espinosae* Steyerm.

EVINGER, E. L.

513 Mitracarpus frigidus var. peruvianus Steyerm.

EWEL, J.

114 Psychotria nematostachya Steyerm.
135 Pochota *ewelii* Steyerm.
209 Brunellia neblinensis Steyerm. & Cuatr.

FAIRBROTHERS

23 Psychotria aristeguietae Steyerm.

FANSHAWE, D. B.

877 Faramea brevipes Steyerm.
1147 Ixora potaroensis Steyerm.
1255 Guettarda *fanshawei* Steyerm.

FARIÑAS, M.

433 Phyllanthus tepuicola Steyerm.

FERRIS, R. (Roxanne)

3391 Grindelia squarrosa var. nuda f. angustior Steyerm.

FLORSCHUTZ, J.

1180 Faramea costata Steyerm.

FOLDATS, E. (Ernesto)

2784 Ouratea subamplexicaulis Maguire & Steyerm.

3670 Palicourea *foldatsii* Steyerm.
3678 Sipaneopsis *foldatsii* Steyerm.
3758 Kotchubaea micrantha Steyerm.
7100 Chimantaea cinerea f. glabra Steyerm.
7192 Hillia *foldatsii* Steyerm.

FOREST DEPT. (Field No.)

CAP 41 Appunia sparsiflora Steyerm.
WB 388 Isertia parviflora var. hirta Steyerm.
WB 500 Appunia tenuiflora var. leiophylla Steyerm.
G 569 Faramea irwinii Steyerm.
F 877 Faramea brevipes Steyerm.

FOREST DEPT. (Record No.)

7227 Ouratea fasciculata Maguire & Steyerm.
7832 Psychotria tetramera Steyerm. (Field No. R.B. 8)

FOSBERG, F. R. (Francis Raymond)

21211 Palicourea guianensis subsp. occidentalis f. glabra Steyerm.
21418 Arachnothrix reflexa var. breviloba Steyerm.
21810 Psychotria *fosbergii* Steyerm.
21825 Amphidasya intermedia Steyerm.
22964 Arachnothrix *fosbergii* Steyerm.
23141 Arachnothrix lojensis Steyerm.

FRÓES, R. L. (Ricardo)

21225 Remijia vaupesiana Steyerm.
21466 Anomospermum steyermarkii Krukoff & Barneby
22885 Henriquezia nitida var. subcuneata Steyerm.

FUNCK & SCHLIM

1500 Palicourea bostrychostachya Steyerm.

GARCIA, F.

55 Palicourea *garciae* Steyerm.

GARCIA, J.

80 Faramea *garciae* Steyerm.
128 Borojoa venezuelensis Steyerm.

GARCIA, T.

147 Chimarrhis microcarpa var. speciosa Steyerm.

GARCIA SALAS, J.

1442 Daphnopsis ficina Standl. & Steyerm.

GATTINGER

s.n. Arenaria patula f. media Steyerm.

GENTLE, P. H. (Percy)

116 Psittacanthus mayanus Standl. & Steyerm.
871 Ipomoea heterodoxa Standl. & Steyerm.
2264 Piper vaccinum Standl. & Steyerm.
2619 Phyllanthus longipes Steyerm.

GENTRY, A. (Alwyn)

46694 Schefflera simplex Steyerm. & Holst
46887 Piper *gentryi* Steyerm.
47314 Sabicea bariensis Steyerm.

GENTRY, H. S. (Howard Scott)

2525 Tinantia erecta f. puberula Standl. & Steyerm.

GHIESBREGHT

871 Arenaria chiapensis Standl. & Steyerm.

GLEASON, H. A. (Henry Allan)

431 Sipanea *gleasonii* Steyerm.

GONZÁLEZ, T. (Tomás)

s.n. Colubrina venezuelensis Steyerm.

GRANT, J. M.

s.n. Grindelia stricta var. aestuarina Steyerm.

GRANT, M. L.

10567 Pentagonia *grantii* Steyerm.

GREENE, E. L. (Edward Lee)

s.n. Grindelia humilis f. reflexa Steyerm.

GREGG, J.

44 Menodora helianthemoides var. engelmannii Steyerm.

GUANCHEZ, F. (Francisco)

3644 Psychotria *guanchezii* Steyerm.

HALL, E. (Elihu)

266 Grindelia integrifolia var. virgata f. villosa Steyerm.

HALLE, F.

1018 Coussarea *hallei* Steyerm.

HARLEY, R. M.

15006 Geophila *harleyi* Steyerm.
16038 Perama *harleyi* Kirkbr. & Steyerm.
17069 Pagamea *harleyi* Steyerm.

HATCH, W. R.

54 Mortoniodendron guatemalense Standl. & Steyerm.
162 Pilea mimema Standl. & Steyerm.

HAUGHT, O.

2190 Psychotria rosea var. trichophora Steyerm.
3068 Faramea occidentalis subsp. lonchocalyx Steyerm.
5400 Hippotis grandiflora Steyerm.

HELLER, A. A. (Amos Arthur)

12579 Grindelia nana var. turbinella Steyerm.

HENDERSON, A. (Andrew)

501 Prestoea humilis Henderson & Steyerm.

HENDERSON, L. F.

2791 Grindelia howellii Steyerm.

HERNÁNDEZ, I. (Lionel)

348 Ochthocosmus micranthus Steyerm.

HEYDE & LUX

6392 Tinantia longipedunculata Standl. & Steyerm.

HOFFMANN

s.n. Grindelia camporum var. abbreviata Steyerm.

HOLST, B. (Bruce Kendall)

3426 Schefflera yutajensis Steyerm. & Holst
3523 Paepalanthus *holstii* Steyerm.
3539 Lindmania *holstii* Steyerm. & L. B. Smith
3617 Ilex summa Steyerm.

HOLT, E. G.

743 Psychotria blakei Standl. & Steyerm.

HOWARD, R. A.

12302 Schradera subsessilis Steyerm.

HOWELL, J. T. (John Thomas)

4352 Grindelia rubricaulis var. permixta Steyerm.
5201 Grindelia camporum var. interioris f. foliacea Steyerm.
5221 Grindelia hirsutula var. brevisquama f. glabrata Steyerm.
5338 Grindelia hirsutula var. brevisquama Steyerm.
5473 Grindelia arenicola Steyerm.
5496 Grindelia camporum var. parviflora Steyerm.
6574 Grindelia rubricaulis var. elata Steyerm.
7545 Grindelia stricta var. aestuarina f. elongata Steyerm.
8106 Grindelia arenicola var. pachyphylla Steyerm.
10805 Grindelia humilis f. pubescens Steyerm.
11414 Grindelia hirsutula var. subintegra Steyerm.
11658 Grindelia maritima f. anomala Steyerm.

HOYOS, J. (Jesús)

46 Kotchubaea morilloi Steyerm.
90 Ouratea asisae Maguire & Steyerm.

HUBER, O. (Otto)

441 Maytenus *huberi* Steyerm.
543 Croton *huberi* Steyerm.
1229 Maytenus insculpta Steyerm.
1447 Ouratea ayacuchae Maguire & Steyerm.
1456 Neea ignicola Steyerm.
1693 Neea robusta Steyerm.
1791 Psychotria yapacanensis Steyerm.
1848 Piper *otto-huberi* Steyerm.
1904 Ouratea *huberi* Maguire & Steyerm.
2504 Ouratea deminuta Maguire & Steyerm.
3759 Tepuianthus savannensis Maguire & Steyerm.
4437 Ilex paruensis Steyerm.
5058 Navia *huberiana* L. B. Smith, Steyerm. & H. Robinson
5481 Ouratea pumila Maguire & Steyerm.
5536 Ouratea pumila var. heterodoxa Maguire & Steyerm.
5763 Ouratea longistyla Maguire & Steyerm.
5786 Sipaneopsis *huberi* Steyerm.
6136 Panopsis parimensis Steyerm.
6184 Navia culcitaria L. B. Smith, Steyerm. & H. Robinson
6945 Aphanocarpus steyermarkii f. elongatus Steyerm.
8246 Sipanea setacea Steyerm.
9123 Coccocypselum *huberi* Steyerm.
9467 Stegolepis *huberi* Steyerm.
9818 Bonnetia bolivarensis Steyerm.
10388 Matayba ptariana subsp. guaiquinimae Steyerm.
11849 Symbolanthus yaviensis Steyerm.

HUMBERT, H. (Henrí)

26739 Psychotria alticola Steyerm.

HUTCHINSON, P. C.

6799 Hillia wurdackii Steyerm.

IJJASZ

425 Psychotria aubletiana var. producta Steverm.

IRWIN, H. S. (Howard)

10161 Psychotria sciaphila subsp. longicalyx Steyerm.
14771 Psychotria hoffmannseggiana var. celsa Steyerm.
18688 Manettia *irwinii* Steyerm.
23537 Hindsia *irwinii* Steyerm.
27120 Mitracarpus pusillus Steyerm.
47354 Palicourea *irwinii* Steyerm.
47393 Psychotria oiapoquensis Steyerm.
47620 Tocoyena guianensis var. communis Steyerm.
54949 Isertia wilhelminensis Steyerm.
55048 Psychotria wilhelminensis Steyerm.
55299 Bertiera diversiramea Steyerm.
55706 Psychotria *irwinii* Steyerm.

JANGOUX, J. (Jacques)

10157 Borreria *jangouxii* Steyerm.
10193 Piper perijaense Steyerm.

JÁTIVA, C. (Carlos)

682 Palicourea guianensis subsp. occidentalis var. glabrescens Steyerm.
735 Psychotria macrophylla subsp. anomothyrsa f. tomentella Steyerm.

JENSEN, L. P.

s.n. Cassia fasciculata f. *jensenii* Palmer & Steyerm.

JOHNSON, H.

523 Poikilacanthus setiferus Standl. & Steyerm.

JOHNSTON, J. R.

1026 Verbesina agricolarum Standl. & Steyerm.
1255 Clethra *johnstonii* Standl. & Steyerm.
1480 Eugenia jutiapensis Standl. & Steyerm.
1525 Berberis *johnstonii* Standl. & Steyerm.
1643 Thalictrum *johnstonii* Standl. & Steyerm.
1812 Hypericum arbuscula Standl. & Steyerm.

1887 Struthanthus *johnstonii* Standl. & Steyerm.

JOLY, C.

5630 Piper arieianum var. yaracuyense f. barbulaense Steyerm.

JOOR

s.n. Grindelia littoralis Steyerm.

JÖRGENSEN, P.

2643 Menodora pinnatisecta Steyerm.
3694 Genipa americana var. caruto f. *jorgensenii* Steyerm.

KELLERMAN, W. A. (William Ashbrook)

5175 Euphorbia pantomalaca Standl. & Steyerm.
7223 Schistocarpha steyermarkii H. Robinson
7223 Senecio steyermarkiana H. Robinson
7532 Serjania macrocarpa Standl. & Steyerm.
7630 Phoradendron treleaseanum Standl. & Steyerm.

KILLIP, E. P. (Ellsworth Paine)

16585 Polygala santanderensis Killip & Steyerm.
26780 Geophila cordifolia var. peruviana Steyerm.

KIRKWOOD, J. E. (Joseph Edward)

20 Menodora coulteri var. minima Steyerm.

KLUG, C.

347 Tetrapterys julianii Macbr.
1969 Mabea *klugii* Steyerm.
2010 Tapura julianii Macbr.
2019 Psychotria subpedicellata Steyerm.
2064 Mabea standleyi Steyerm.
2164 Bertiera guianensis subsp. pubiflora Steyerm.
2362 Coussarea *klugii* Steyerm.
3084 Hippotis subelongata Steyerm.
3206 Mabea elata Steyerm.
3452 Kotchubaea montana Steyerm.

KOYAMA, T. (Tetsuo)

7506 Mapania steyermarkii T. Koyama

KRUKOFF, B. A. (Boris Alexander)

3 Retiniphyllum laxiflorum var. brasiliense Steyerm.
1983 Mabea pirioides Steyerm.
4940 Psychotria embirensis Steyerm.
6210 Drypetes amazonica Steyerm.
6297 Omphalea elaeophoroides Steyerm.
6455 Pseudoconnarus *krukovii* Steyerm.
6858 Psychotria megacephala Steyerm.
8396 Conceveiba *krukoffii* Steyerm.
8513 Richeria submembranacea Steyerm.
8556 Rourea *krukovii* Steyerm.
8616 Conceveiba simulata Steyerm.
8698 Conceveiba magnifica Steyerm.
10650 Elaeagia microcarpa Steyerm.

KUNTZE, O. (Carl Ernst Otto)

1643 Mitracarpus frigidus var. andinus Steyerm.

KUYLEN, H.

151 Clethra bimatris Standl. & Steyerm.

LANJOUW, J. (Joseph)

802 Palicourea crocea var. riparia f. heterodoxa Steyerm.

LASSER, T. (Tobias)

1042 Palicourea perquadrangularis var. brevipes Steyerm.
1156 Palicourea *lasseri* Steyerm.
1221 Palicourea insignis Steyerm.
1417 Coccocypselum guianense var. patens Steyerm.
1682 Coussarea *lasseri* Steyerm.
2047 Psychotria araguensis Steyerm.

LASSER, T. & J. A. STEYERMARK

55103 Symplocos *lasseri* Steyerm. (possibly a Steyermark number)

LEPRIEUR, F. R. M.

118 Psychotria pungens Steyerm.

LESUER, H. (Harde)

1016 Grindelia confusa Steyerm.

LIESNER, R. L. (Ronald)

4096 Neea mapourioides Steyerm.
5991 Rauia subtruncata Steyerm.
6222 Piper pseudoacreanum Steyerm.
6405 Piper *liesneri* Steyerm.
7729 Peperomia falconensis Steyerm.
8176 Piper cerronianum Steyerm.
8211 Piper wingfieldii Steyerm.
8959 Neea sebastianii Steyerm.
9699 Piper sierra-aroense Steyerm.
9767 Piper cordiforme Steyerm.
10022 Piper linguliforme Steyerm.
10107 Psychotria aubletiana var. villipila Steyerm.
10494 Piper arieianum var. yaracuyense f. puberulum Steyerm.
10555 Peperomia fundacionensis Steyerm.
10891 Piper longiappendiculatum Steyerm.
11151 Talisia heterodoxa Steyerm.
11277 Neea bracteosa Steyerm.
11479 Sloanea bolivarensis Steyerm.
11647 Piper fundacionense Steyerm.
11873 Piper *ronaldii* Steyerm.
15866 Navia *liesneri* L. B. Smith, Steyerm. & H. Robinson
15955 Psychotria pectinata Steyerm.
16013 Pagameopsis maguirei subsp. pusillus Steyerm.
16025 Navia filifera L. B. Smith, Steyerm. & H. Robinson
16026 Navia crassicaulis L. B. Smith, Steyerm. & H. Robinson
16355 Pochota mawarinumae Steyerm.
16502 Neea *liesneri* Steyerm.
16605 Raveniopsis *liesneri* Steyerm.
16688 Ilex glabella Steyerm.
16720 Maytenus pustulata Steyerm.
16809 Sauvagesia marahuacensis subsp. neblinensis Steyerm.
16901 Peperomia gentryi Steyerm.
16960 Faramea paludicola Steyerm.
16963 Psychotria thesceloantha Steyerm.

17493 Coussarea evoluta Steyerm.
17599 Ilex spathulata Steyerm.
17677a Sauvagesia marahuacensis Steyerm.
18214 Psychotria *ronaldii* Steyerm.
18403 Neea huachamacarae Steyerm.
18428 Neea marahuacae Steyerm.
18452 Pochota fuscolepidota Steyerm.
18455 Sloanea longiaristata Steyerm.
18469 Ilex *liesneri* Steyerm.
18595 Ilex acutidenticulata Steyerm.
18637 Pochota *liesneri* Steyerm.
18796 Ilex paujiensis Steyerm.
19479 Ilex ciliolata Steyerm.
19595 Psychotria edaphothrix Steyerm.
19878 Ilex longipilosa Steyerm.
20394 Talisia maruayana Steyerm.
20394 Talisia amaruayiensis Steyerm., ined. mss.
20514 Neea amaruayensis Steyerm.
20800 Guapira bolivarensis Steyerm.
21248 Pochota redmondii Steyerm.
21640 Faramea yutajensis Steyerm.
21649 Psychotria yutajensis Steyerm.
21826 Yutajea *liesneri* Steyerm.
21827 Rudgea corocoroensis Steyerm.
21904 Aechmea siapensis L. B. Smith & Steyerm.
21968 Piper mosaicum Steyerm.
21998 Navia terramarae L. B. Smith & Steyerm.
22041 Navia patria L. B. Smith & Steyerm.
22062 Navia platyphylla L. B. Smith & Steyerm.
22064 Cephalodendron aracamuniensis Steyerm.
22075 Sauvagesia guianensis subsp. aracamuniensis Steyerm.
22079 Symbolanthus aracamuniensis Steyerm.
22105 Bonnetia *liesneri* Steyerm.
22153 Neblinathamnus aracamunianus Steyerm.
22197 **Rapatea aracamuniana Steyerm.**
22203 Navia iosothrix L. B. Smith & Steyerm.
22262 Coussarea *liesneri* Steyerm.
22322 Navia carnevalii L. B. Smith & Steyerm.
22407 **Remijia reducta Steyerm.**
22473 Ilex aracamuniana Steyerm.
22559 Pochota aracamuniana Steyerm.
22622 Hexapterella steyermarkii Maas & Maas

LIGGETT, W. E. (William)

1 Echinacea purpurea f. *liggettii* Steyerm.

LINDHEIMER, F. (Ferdinand Jacob)

255 Grindelia microcephala var. adenodonta Steyerm.

LITTLE, E. L. (Elbert Luther)

9533 Pagamea guianensis var. macrocarpa Steyerm.
15238 Psychotria aubletiana var. andina f. pubescens Steyerm.
15354 Simira erythroxylon var. meridensis Steyerm.
15372 Guettarda steyermarkii f. pilosior Steyerm.

LUNDELL, C. L. (Cyrus Longworth)

2012 Solanum decurtatum Standl. & Steyerm.
2213 Annona primigenia Standl. & Steyerm.
3153 Lisianthius petenensis Standl. & Steyerm.
6193 Psychotria schippii Standl. & Steyerm.

LUTEYN, J. L. (James Leonard)

9413 Raveniopsis cowaniana Steyerm. & Luteyn
9610 Connellia smithiana Steyerm. & Luteyn

MADRIZ, A.

37 Trigonia costanensis Steyerm. & Badillo

MAGUIRE, B. (Bassett)

2874 Catostemma ebracteolatum Steyerm.
3558 Dendrosipanea wurdackii Steyerm.
4612 Borreria cataractarum Steyerm.
23072 Coussarea fanshawei Steyerm.
23204 Utricularia kaieteurensis Steyerm.
23249 Utricularia *maguirei* Steyerm.
24361 Retiniphyllum *maguirei* var. reticulatum Steyerm.
24393 Duroia eriopila var. tafelbergensis Steyerm.
24530 Malanea tafelbergensis Steyerm.
24874 Malanea sarmentosa f. tomentosa Steyerm.
27324 Sipanea pratensis var. dichotoma f. brachycarpa Steyerm.
27485 Ouratea ornata Maguire & Steyerm.
27631 Ouratea sipapoensis Maguire & Steyerm.
27674 Sloanea sipapoana Steyerm.
27756 Schefflera guanayensis subsp. sipapoensis Maguire, Steyerm. & Frodin
27864 Psychotria everardii subsp. sipapoensis Steyerm.
27869 Retiniphyllum laxiflorum var. longilobum Steyerm.
27895 Schradera brevipes Steyerm.
27971 Chimarrhis brevipes Steyerm.
28013 Remijia sipapoensis Steyerm.
28243 Meruma coccocypseloides Steyerm.
28349 Thibaudia smithiana Maguire, Steyerm. & Luteyn
28399 Matayba oligandra var. occidentalis Steyerm.
28409 Panopsis cuaoensis Steyerm.
28454 Schefflera pauciradiata Maguire, Steyerm. & Frodin
28458 Retiniphyllum tepuiense Steyerm.
28471 Schefflera sipapoensis Maguire, Steyerm. & Frodin
28483 Rudgea sipapoensis Steyerm.
28516 Piper politii subsp. sipapoense Steyerm.
28536 Pagamea velutina Steyerm.
28615 Talisia caudata Steyerm.
28626 Chimarrhis bathysoides Steyerm.
28656 Rhamnus sipapoensis Steyerm.
28741 Catostemma ebracteolatum Steyerm.
28743 Malanea sipapoensis Steyerm.
28778 Psychotria sipapoensis Steyerm.

29079 Remijia densiflora f. glabricalyx Steyerm.
29137 Sabicea velutina subsp. duidense Steyerm.
29242a Borreria pygmaea var. robusta Steyerm.
29253 Ouratea evoluta Maguire & Steyerm.
29469 Randia amazonasensis Steyerm.
29529 Perissocarpa umbellifera Steyerm. & Maguire
29543 Tepuianthus sarisarinamensis subsp. duidensis Maguire & Steyerm.
29546 Schefflera pedicelligera Maguire, Steyerm. & Frodin
29564 Thibaudia longipes Maguire, Steyerm. & Luteyn
29573 Pagamea capitata subsp. conferta f. breviloba Steyerm.
29786 Psychotria lourteigiana Steyerm.
29851 Psychotria adenophora Steyerm.
29859 Symbolanthus huachamacariensis Steyerm.
30001 Styrax tepuiensis subsp. huachamacarii Maguire & Steyerm.
30253 Schefflera huachamacarii Maguire, Steyerm. & Frodin
30285 Laplacea pubescens var. minor Steyerm.
30458 Sipanea glomerata var. paucinervia Steyerm.
30557 Ochthocosmus multiforus var. angustifolius Steyerm. & Luteyn
30632 Bonnetia tristyla subsp. nervosa Steyerm. (superfluous, illegitimate)
30683 Tepuianthus yapacanensis Maguire & Steyerm.
30766 Ouratea rotundipetala Maguire & Steyerm.
30878 Sipaneopsis morichensis Steyerm.
30881 Rudgea morichensis Steyerm.
30886 Perama galioides var. hispida f. cinerea Steyerm.
30945 Orthaea thibaudioides Maguire, Steyerm. & Luteyn
31740 Schefflera guanayensis Maguire, Steyerm. & Frodin
31823 Psychotria glandulicalyx subsp. camaniensis Steyerm.
32219 Calycophyllum spectabile Steyerm.
32329 Faramea fanshawei Steyerm.

51601 Duroia amapana Steyerm.
52250 Psychotria *piresii* Steyerm.
52451 Genipa spruceana Steyerm.

NASCIMENTO, O. C.
20 Psychotria formosissima Steyerm.

NEE, M. (Mike)
30967 Remijia sessilis Steyerm.

NELSON, E. W. (Edward William)
6523 Grindelia sublanuginosa Steyerm.
6864 Grindelia *nelsonii* Steyerm.

NELSON, J. C.
1670 Grindelia integrifolia f. dentata Steyerm.

OLDEMAN
209 Chomelia glabriuscula Steyerm.

OLDERMAN, R. A. A.
B-627 Rudgea oldemanii Steyerm.

OLIVA ESTEVA, F. (Francisco)
s.n. Brocchinia oliva-estevae Steyerm. & L. B. Smith

ORCUTT, C. R. (Charles Russell)
1204 Grindelia greenei Steyerm.

OWNBEY
2739 Joosia macrocalyx Standl. ex Steyerm.

PALMER, E. (Edward)
163 Grindelia *palmeri* Steyerm.
316 Grindelia oxylepis f. eligulata Steyerm.
429 Menodora decemfida var. longifolia Steyerm.
469 Grindelia microcephala var. pusilla Steyerm.
471 Grindelia greenmanii Steyerm.
520 Grindelia oxylepis var. capitellata Steyerm.

PALMER, E. J. (Ernest Jesse)
16342 Quercus ×inaequalis Palmer & Steyerm.
18928 Sambucus canadensis f. rubra Palmer & Steyerm.
21923 Benzoin aestivale var. pubescens Palmer & Steyerm.
25421 Quercus ×vaga Palmer & Steyerm.
26069 Quercus ×mutabilis Palmer & Steyerm.
31083 Menodora scabra var. ramosissima Steyerm.
33590 Grindelia microcephala var. adenodonta f. angustior Steyerm.
35387 Cladrastis lutea f. tomentosa Steyerm.
39039 Rosa setigera f. inermis Palmer & Steyerm.
40317 Amelanchier canadensis f. nuda Palmer & Steyerm.
41450 Ludvigia alternifolia var. pubescens Palmer & Steyerm.
41642 Rosa setigera f. serena Palmer & Steyerm.
55411 Phlox divaricata var. laphamii f. candida Palmer & Steyerm.
59655 Rubus flagellaris f. roseo-plenus Palmer & Steyerm.
61259 Vernonia bladwinii f. albiflora Steyerm.
65070 Phacelia hirsuta f. albiflora Palmer & Steyerm.

PARISH, S. B. (Samuel Bonsall)
9795 Menodora spinescens var. mohavensis Steyerm.

PARRY, C. C. (Charles Christopher)
570pp Menodora helianthemoides var. magniflora Steyerm.
571pp Menodora helianthemoides var. humilis Steyerm.

PEGLER
950 Menodora heterophylla var. australis Steyerm.

PEÑA, B. S.
s.n. Psychotria fimbriflora Steyerm.

PENNELL, F. W. (Francis Whittier)
1676 Coccocypselum brevipetiolatum Steyerm.

PHELPS, K. D. (Kathleen Deery)
366 Pagamea reducta Steyerm.

PHILIPSON
2072 Joosia umbellifera subsp. macarensis Steyerm.

PINKUS, A. S.
90 Hiraea tepuiensis Steyerm.
92 Calycolpus roraimensis Steyerm.
277 Ouratea pseudotatei Maguire & Steyerm.

PIPOLY, J.
6838 Tepuianthus aracensis Steyerm. & Maguire

PITTIER, H. (Henrí Francois)
5178 Bertiera guianensis var. leiophylla Steyerm.
7911 Psychotria microdon var. meridionalis Steyerm.
9829 Borreria laevis var. edentata Steyerm.
9967 Guettarda crispiflora var. venezuelensis Steyerm.
10948 Faramea multiflora var. epedunculata Steyerm.
11995 Rondeletia venezuelensis Steyerm.
12192 Faramea occidentalis var. meridionalis Steyerm.
13498 Rudgea costanensis Steyerm.
14010 Psychotria berteriana subsp. venezuelica Steyerm.
14103 Hippotis lasseri Steyerm.

PLOWMAN, T. (Timothy)
13610 Maytenus neblinae Steyerm.

PRANCE, G. T. (Ghillean)
7606 Duroia hirsutissima Steyerm.
8985 Geophila *prancei* Steyerm.
9015 Psychotria *prancei* Steyerm.
10528 Sipanea *prancei* Steyerm.
14739 Rudgea *prancei* Steyerm.
29016 Raveniopsis aracaënsis Kallunki & Steyerm.
59234 Duroia *prancei* Steyerm.

PURPUS, C. A. (Carl Albert)
1318 Menodora intricata var. *purpusii* Steyerm.
5722 Grindelia robinsonii Steyerm.
12091 Aster bimater Standl. & Steyerm.
16201 Tinantia leiocalyx f. glabra Standl. & Steyerm.

RAMIA, M. (Mauricio)
5254 Chomelia *ramiae* Steyerm.

REDMOND, P. (Parker)
s.n. Erythrina poeppigiana f. *redmondii* Steyerm. & Lasser

ROADHOUSE, F. E.
65 Grindelia hirsutula var. calva Steyerm.

ROHL, E.
103 Chomelia venezuelensis Steyerm.

ROSA, N. A.
706 Pagamea acrensis Steyerm.

RUÍZ-TERÁN, L. E.
441 Elaeagia *ruiz-teranii* Steyerm.
1433 Tocoyena costanensis subsp. andina Steyerm.
2980 Psychotria blepharophora var. pubens Steyerm.
3199 Psychotria *ruiz-teranii* Steyerm.
3746 Palicourea angustifolia var. glabricaulis Steyerm.
4703 Rudgea *ruiz-teranii* Steyerm.
6461 Peperomia acuminata f. rubra Steyerm.
10907 Lantana *ruiz-teranii* López-Palacios & Steyerm.

RUNYON
875 Orthrosanthus chimboracensis var. exsertus f. albus Steyerm.

RUSBY, H. H. (Henry Hurd)
s.n. Psychotria occidentalis Steyerm.

SAER, J.
4 Chiococca alba subsp. parvifolia var. micrantha f. pilosa Steyerm.
635 Gonzalagunia ciliata Steyerm.
727 Rondeletia larensis Steyerm.

SASTRE, C. (Claude)
934 Sabicea *sastrei* Steyerm.
2392 Psychotria *sastrei* Steyerm.
6463 Psychotria cypellantha Steyerm.

SCHIPP, W. A.
674 Cynanchum stenomeres Standl. & Steyerm.

SCHLIM, L.
531 Faramea pseudospathacea Steyerm.

SCHMITT, W. F.
s.n. Grindelia arenicola f. trichophora Steyerm.

SCHNEE, L. (Ludwig)
1577 Xyris *schneeana* L. B. Smith & Steyerm.

SCHOMBURGK, R. (Robert Hermann)
282 Psychotria cordifolia subsp. perpusilla Steyerm.
924 Chomelia *schomburgkii* Steyerm.
955 Ferdinandusa goudotiana var. eciliata Steyerm.

SCHULTES, R. E. (Richard Evens)
46-357 Retiniphyllum truncatum var. angustifolium Steyerm.

8156 Coussarea hirticalyx var. glabrior Steyerm.
9100 Retiniphyllum glabrum Steyerm.
13075 Hillia *schultesii* Steyerm.
14475 Ferdinandusa *schultesii* Steyerm.
15031 Stenopadus colombianus Cuatr. & Steyerm.
15056 Tepuianthus colombianus Maguire & Steyerm.
19367 Pagamea coriacea var. acuta Steyerm.
19929 Platycarpum *schultesii* Steyerm. ex Schultes
20061 Perama *schultesii* Steyerm.

SHAFER, J. A. (John Adolf)
8805 Psychotria deflexa subsp. cubensis Steyerm.

SHANTZ, H. L. (Homer LeRoy)
597 Grindelia inornata var. angusta Steyerm.

SHREVE, F. (Forrest)
8035 Viguiera *shrevei* Steyerm.

SILVA N. T. (Nilo)
81 Psychotria quadribracteata Steyerm.
60606 Neea grandis Maguire & Steyerm.
60607 Psychotria heteroneura Steyerm.
60633 Psychotria brazoi Steyerm.
60678 Mollinedia neblinensis Maguire & Steyerm.

129816 Phyllanthus jablonskianus Steyerm. & Luteyn
129924 Acopanea ahogadoi Steyerm.
129932 Chimantaea acopanensis Steyerm.
129962 Stegolepis maguireana Steyerm.
130072 Steyerbromelia diffusa L. B. Smith, Steyerm. & H. Robinson
130112 Ilex ignicola Steyerm.
130135 Tillandsia abysmophila L. B. Smith & Steyerm.
130228 Ochthocosmus berryi Steyerm.
130318a Navia berryana L. B. Smith, Steyerm. & H. Robinson
130328 Phyllanthus vacciniifolius var. vinillaensis Steyerm.
130339 Remijia delascioi Steyerm.
130410 Navia delascionis L. B. Smith, Steyerm. & H. Robinson
130425 Ilex marahuacae Steyerm.
130440 Remijia marahuacensis Steyerm.
130481 Ilex holstii Steyerm.
130531 Ilex brevipedicellata Steyerm.
130629 Gongylolepis terramarae Steyerm.
130637 Holstianthus barbigularis Steyerm.
130721 Schradera marahuacensis Steyerm.
130742a Peperomia marahuacensis Steyerm.
130878 Catostemma marahuacensis Steyerm.
130880 Lissocarpa stenocarpa Steyerm.
130907 Ouratea marahuacensis Maguire & Steyerm.
131659 Simira ignicola Steyerm.
131850 Navia grafii Steyerm. & Holst
131868 Symplocos acananensis Steyerm.
132006 Stegolepis humilis Steyerm.

SUKSDORF, W. N. (Wilhelm Nikolaus)

279 Grindelia hirsutala var. brevisquama f. tomentulosa Steyerm.

SWINK, F. A.

2775 Vernonia missurica f. *swinkii* Steyerm.

TAMAYO, F. (Francisco)

3133 Duroia gransabanensis Steyerm.
4509 Arcytophyllum nitidum subsp. caracasanum var. culmenicolum Steyerm.

TATE, G. H. H. (George Henry Hamilton)

424 Ilex culmenicola Steyerm.
431 Schefflera umbellata subsp. duidana Maguire, Steyerm. & Frodin
526 Ilex gleasoniana Steyerm.
567 Pagamea duidana Standl. & Steyerm.
1147 Borreria oligodonta Steyerm.
1365 Pagamea auyantepuiensis Steyerm.

3245 Navia *thomasii* L. B. Smith, Steyerm. & H. Robinson

THURN, I. (Everard Ferdinand Im)

162 Schefflera monosperma Maguire, Steyerm. & Frodin

TILLETT, S. S. (Steven)

82 Croizatia naiguatensis Steyerm.
738-366 Manettia honigii Steyerm.
743-230 Peperomia atabapoensis Steyerm.
745-385 Sabicea *tillettii* Steyerm.
746-501 Manettia *tillettii* Steyerm.
746-798 Peperomia honigii Steyerm.
752-329 Siphocampylus *tillettii* Steyerm.
752-348 Duidaea marahuacensis Steyerm.

761-83 Peperomia *tillettii* Steyerm.
43934 Rudgea *tillettii* Steyerm.
43944 Merumea plicata Steyerm.
43946 Psychotria *tillettii* Steyerm.
43954 Psychotria boyanii Steyerm.
43996 Psychotria merumensis Steyerm.
44824 Retiniphyllum guianense Steyerm.
44825 Rudgea merumensis Steyerm.
44835 Duroia merumensis Steyerm.
44837 Calycophyllum merumense Steyerm.
44867 Orthaea merumensis Maguire, Steyerm. & Luteyn
44992 Schradera ternata Steyerm.
45007 Psychotria psittacina Steyerm.
45008 Psychotria urniformis Steyerm.
45057 Ceratostema glandulifera Maguire, Steyerm. & Luteyn
45059 Psychotria ayangannensis Steyerm.
45079 Psychotria multiramosa Steyerm.
45081 Malanea ciliolata Steyerm.
45085 Ixora intropilosa Steyerm.
45105 Psychotria amplinoda var. ayangannae Steyerm.
45180 Alibertia triloba Steyerm.
45184 Ferdinandusa goudotiana var. psilocarpa Steyerm.
45194 Retiniphyllum scabrum var. ayangannense Steyerm.
45114 Sipanea ayangannensis Steyerm.
45117 Rudgea enervia Steyerm.
45178 Schefflera ayangannensis Maguire, Steyerm. & Frodin
45182 Rudgea ayangannensis Steyerm.
45501 Piper perstipulare Steyerm.
45567 Calycophyllum intonsum Steyerm.

TORRES LEZAMAE, A.

203 Simira *lezamae* Steyerm.

TRACY, J. P. (Joseph Prince)

4669 Grindelia nana var. altissima Steyerm.

TRELEASE, W. (William)

s.n. Grindelia lanceolata f. latifolia Steyerm.

TRUJILLO, B. (Baltasar)

766 Psychotria fernandezii Steyerm.
1374 Psychotria avilensis Steyerm.
1921 Psychotria *trujilloi* Steyerm.
1955 Psychotria terepaimensis Steyerm.
2763 Faramea larensis Steyerm.
6555 Rudgea *trujilloi* Steyerm.
7594 Hoffmannia bernardii var. aracalensis Steyerm.
7919 Peperomia *trujilloi* Steyerm.

TUCKER, J. M.

979 Hyperbaena salvadorensis Steyerm.
1368 Bouvardia salvadorensis Steyerm.

ULE, E. (Ernst Heinrich Georg)

5386 Psychotria manausensis Steyerm.
6795 Joosia *ulei* Steyerm.

VAN DER WERFF, H. (Henk)

237 Peperomia ouabiane var. sanluisensis Steyerm.
548 Piper arieianum var. yaracuyense f. falconense Steyerm.
3642 Piper galicianum f. hirsutopetiolatum Steyerm.
5457 Faramea cazaderensis Steyerm.

VARADARAJAN, G. S.

1205 Connellia *varadarajanii* L. B. Smith & Steyerm.

VARESCHI, V. (Volkmar)

1386 Rudgea *vareschii* Steyerm.
4966 Tepuia *vareschii* Steyerm.
6850 Arcytophyllum *vareschii* Steyerm.
7790 Psychotria *vareschii* Steyerm.

VEILLON, J. P.

7 Dendropanax *veillonii* Steyerm.
14 Styrax andinus Steyerm.

VELASCO, R.

627 Palicourea flexiramea Steyerm.

VOGEL, S. (Stefan)

81 Psychotria caquetensis Steyerm.
290 Psychotria capitata f. trichophora Steyerm.
312 Palicourea *vogelii* Steyerm.

VOGL, PADRE C. (Cornelio)

41 Aspilia avilensis Aristeg. & Steyerm.

VON HAGEN, C. & W. (Cristine & Wolfgang)

2137 Chione panamensis Steyerm.

VON TUERCKHEIM, H. or von Türckheim (Hans)

1240 Struthanthus papillosus Standl. & Steyerm.
1617 Xylosma sessile Standl. & Steyerm.
1728 Elaterium macrophyllum Standl. & Steyerm.
1732 Polymnia verapazensis Standl. & Steyerm.
8410 Jungia guatemalensis Standl. & Steyerm.

WESSELS-BOER, J. G.

962 Psychotria *wessels-boeri* Steyerm.
1953 Schoenobiblus amazonicus Steyerm.

WHITEHOUSE, E. (Eula)

s.n. Selenia oinosepala Steyerm.

WHITTON, B. A.

120 Chiococca multipedunculata Steyerm.

WILLIAMS L. (Llewelyn)

10639 Utricularia *williamsii* Steyerm.
11505 Eugenia caurensis Steyerm.
11691 Myrciaria caurensis Steyerm.
12073 Palicourea rigida var. hirtibacca Steyerm.
12970 Chalepophyllum pungens Standl. & Steyerm.
12992 Psychotria calviflora Steyerm.
13178 Carex standleyana Steyerm.
13329 Rondeletia orinocensis Steyerm.
13650 Maytenus pittieriana Steyerm.
13853 Borreria macrocephala Standl. & Steyerm.
13918 Picramnia tristamina Steyerm.
13922 Philonotion *williamsii* Steyerm.
14026 Faramea yavitensis Steyerm.

14140 Caraipa ferruginea Steyerm.
14143 Clusia *williamsii* Steyerm.
14152 Ouratea venezuelensis Steyerm.
14154 Glandonia *williamsii* Steyerm.
14162 Vochysia steyermarkii Marcano Berti
14190 Pagamea plicatiformis Steyerm.
14312 Chaetocarpus *williamsii* Steyerm.
14321 Burdachia *williamsii* Steyerm.
14439 Amanoa pubescens Steyerm.
14525 Posoqueria *williamsii* Steyerm.
14587 Platycarpum decipiens Woodson & Steyerm.
14674 Rudgea carolina Standl. & Steyerm.
14898 Clusia reducta Steyerm.
14962 Eugenia llewelynii Steyerm.
14983 Psychotria ventuariana Standl. & Steyerm.
15067 Perama galioides f. quaternata Steyerm.
15532 Calathea acuminata Steyerm.
15564 Ryania casiquiarensis Steyerm.
15656 Sipanea pubinoda Steyerm.
16039 Tocoyena brevifolia Steyerm.

WILLIAMS, L. O. (Louis Otho)

11237 Psychotria aubletiana var. centro-americana Steyerm.
13178 Carex standleyana Steyerm.

WILSON, C. L. (Carl Louis)

175 Triolena izabalensis Standl. & Steyerm.
188 Tetrorchidium brevifolium Standl. & Steyerm.
272 Euphorbia verapazensis Standl. & Steyerm.
329 Hybanthus sylvicola Standl. & Steyerm.
356 Lisianthius calciphilus Standl. & Steyerm.

WINGFIELD, R. (Robert)

5495 Piper diffamatum var. angustius Steyerm.
6571 Piper pseudodivulgatum Steyerm.

WOOTON, E. O. (Elmer Ottis)

s.n. Grindelia acutifolia Steyerm.
2568 Grindelia arizonica var. stenophylla Steyerm.

WURDACK, J. J. (John Julius)

911 Hoffmannia parvifolia Steyerm.
961 Perama *wurdackii* Steyerm.
1817 Hippotis latifolia Steyerm.
2089 Hippotis *wurdackii* Steyerm.
2435 Pentagonia *wurdackii* Steyerm.
2461 Simira *wurdackii* Steyerm.
2523 Pentagonia parvifolia Steyerm.
34112 Eupatorium ibaguense var. indiscretum Maguire, Steyerm. & Wurd.
34201 Sauvagesia imthurniana subsp. chimantensis Maguire, Steyerm. & Wurd.
34225 Chimantaea eriocephala Maguire, Steyerm. & Wurd.
34262 Heliamphora heterodoxa var. exappendiculata Maguire & Steyerm.
39784 Alibertia latifolia var. pargueniana Steyerm.
39810 Gouania *wurdackii* Steyerm.
39823 Sipanea pratensis var. dichotoma f. glabrior Steyerm.
39858 Simira erythroxylon var. saxicola Steyerm.
40970 Chomelia monachinoi Steyerm.
41017 Sloanea *wurdackii* Steyerm.
41253 Toulicia anomala Steyerm.
41303 Randia venezuelensis Steyerm.
42698 Mitracarpus frigidus var. orinocensis Steyerm.
42701 Borreria confertifolia Steyerm.
42719 Ouratea *wurdackii* Maguire & Steyerm.
42727 Rudgea *wurdackii* Steyerm.
42824 Remijia *wurdackii* Steyerm.
42833 Sabicea brachycalyx Steyerm.
42915 Borreria *wurdackii* Steyerm.
42916 Sipanea pratensis var. dichotoma f. glabriloba Steyerm.
42988 Borreria intricata Steyerm.
43078 Coussarea revoluta Steyerm.
43148 Schefflera tamatamaensis Maguire, Steyerm. & Frodin
43316 Schradera hilliifolia Steyerm.
43383 Capirona *wurdackii* Steyerm.
43692 Perama galioides var. longiflora Steyerm.
43762 Euphronia acuminatissima Steyerm.

YUNCKER, T. G. (Truman George)

8323 Erblichia standleyi Steyerm.
8519 Mortoniodendron membranaceum Standl. & Steyerm.

APPENDIX III. *Family Index.* Numbers of taxa described by Steyermark arranged alphabetically by family.

Family	Genera	Species	Subspecies	Varieties	Forms	Miscellaneous
Acanthaceae	6	2	—	1	5	—
Actinidiaceae	1	9	—	—	—	—
Agavaceae	1	—	—	—	—	—

SYSTEMATICS OF *ZAPOTECA* (LEGUMINOSAE)[1]

Héctor M. Hernández[2]

Abstract

Zapoteca (Leguminosae: Mimosoideae) is a relatively well-circumscribed genus belonging to the tribe Ingeae distributed from the southwestern United States and northern Mexico to northern Argentina and the West Indies. The highest concentration of taxa occurs in the dry forests of southern Mexico and, to a lesser extent, in Central America and the northern Andes. The predominance of allopatric distributions and the apparent low frequency of hybrids suggest that speciation in this genus has primarily arisen from genetic differentiation of geographically isolated populations. The recent climatic episodes of the Pleistocene appear to have had a prominent role on the current distributional patterns of *Zapoteca* species. *Zapoteca* species have similar reproductive biologies. All probably have nocturnal anthesis and are pollinated by unspecialized settling moths. Self-compatibility appears to be widespread in the genus, *Z. tetragona* being the only known self-incompatible species. Andromonoecy is another widespread component of the breeding system of *Zapoteca* species. This probably maximizes the use of reproductive energy without reducing pollinator attraction. The basic chromosome number of *Zapoteca* ($x = 13$) and some of the generalized characters of the polyads (i.e., acalymmate, discoid, 16-grained polyads) indicate a relationship between *Zapoteca* and the remaining genera of the Ingeae, with the exception of *Calliandra* sensu stricto, which is cytologically and morphologically isolated in this tribe. I recognize 17 species in *Zapoteca*, three of which (*Z. alinae*, *Z. andina*, and *Z. tehuana*) are newly described. Eleven subspecies are recognized, of which *Z. portoricensis* subsp. *pubicarpa* is newly described. A subgeneric classification is proposed, where taxa are grouped into four morphologically distinct subgenera: *Nervosa*, *Zapoteca*, *Aculeata*, and *Amazonica*. The subgenera are based primarily on differences in vegetative characters: number of pairs of pinnae, number of leaflet pairs per pinna, leaflet size, leaflet texture, venation patterns, and stipule type.

Resumen

Zapoteca (Leguminosae: Mimosoideae) es un género relativamente bien delimitado que pertenece a la tribu Ingeae. Se distribuye desde el suroeste de los Estados Unidos y el norte de México hasta el norte de Argentina y las Antillas. La más alta concentración de taxa se da en los bosques tropicales secos del sur de México y, en menor medida, en Centro América y en la porción norte de los Andes. La predominancia de distribuciones alopátricas, en combinación

---

[1] This study is part of my doctoral thesis at Saint Louis University, Saint Louis, Missouri. I thank Dr. Peter H. Raven, Director of the Missouri Botanical Garden, for directing my research and for support and encouragement in all stages of the project. The Missouri Botanical Garden provided office space and herbarium, library, and greenhouse facilities. The assistance of the staff and technicians of the Missouri Botanical Garden was essential and is gratefully acknowledged.

I also thank Drs. Rupert Barneby, Gerrit Davidse, John Dwyer, Alwyn Gentry, Mario Sousa, and an anonymous reviewer for reading the manuscript and providing helpful comments and editorial advice; Ph. Guinet, R. Keating, S. Koptur, P. Lowry, and B. Stein for critically reading parts of the manuscript; J. Dwyer for providing the Latin descriptions of the new taxa; C. Beutelspacher for identifying the flower visitors; J. Myers for his excellent botanical illustrations; F. Villegas for Figure 44; M. Veith and M. Reyes for assistance in the use of the SEM at Washington University and Instituto de Geología, UNAM, respectively; and D. Thiel for typing part of the exsiccata. I am especially grateful to the following persons who provided seed samples and other botanical material: M. Correa, A. Delgado, C. Dodson, E. Forero, C. Hughes, C. Johnson, J. Lewis, E. Lott, J. Miller, D. Neill, J. Oakes, P. Robbertse, D. Smith, W. Stevens, R. Torres, J. Vassal, T. Wendt, and T. Zanoni. I also thank the curators of the following herbaria for providing specimens: A, BM, BR, CAS, CGE, ENCB, F, G, GH, GOET, K, LE, MA, MEXU, MICH, NY, P, S, TEX, UC, US, WIS, and XAL.

Field studies would not have been possible without the financial assistance of the Missouri Botanical Garden and World Wildlife Fund U.S. (Tropical Botany Fellowship). I thank the following individuals who provided assistance in the field: M. Arredondo, S. Arredondo, H. Churchil, M. Correa, M. Grayum, P. Grayum, L. Hernández, D. Janzen, P. Moreno, A. Ramírez, A. Shilom Ton, W. D. Stevens, P. Tenorio, and R. Torres.

The five-year stay in Saint Louis, Missouri was made possible for my family and me by a scholarship provided by the Instituto de Biología, Universidad Nacional Autónoma de México, through the Departamento de Becas. I express sincere gratitude to Dr. José Sarukhán K., then director of the Instituto de Biología, and Dr. Mario Sousa S., former curator of the Herbario Nacional de México (MEXU) for their confidence and continuous support. Thanks are extended to the Missouri Botanical Garden for partial financial support during our last year in Saint Louis. Finally, my deep thanks to my wife Alina and to Pablo for their love and emotional support during this long experience.

[2] Missouri Botanical Garden, P.O. Box 299, Saint Louis, Missouri 63166, U.S.A. Present address: Herbario Nacional de México, Instituto de Biología, Universidad Nacional Autónoma de México, Apartado Postal 70-367, Ciudad Universitaria, 04510, México, D.F., México.

con la aparente baja frecuencia de híbridos, sugiere que la especiación en este género ha sido el resultado de un proceso de diferenciación genética de poblaciones aisladas geográficamente. Los episodios climáticos recientes de Pleistoceno posiblemente tuvieron un papel determinante sobre los patrones de distribución actuales de las especies de *Zapoteca*. Las especies de *Zapoteca* son bastante uniformes en los rasgos generales de su biología reproductiva. Todas tienen posiblemente flores con antesis nocturna y son polinizadas por palomillas no especializadas. Los sistemas de auto-compatibilidad genética parecen estar bién representados en el género, *Z. tetragona* siendo la única especie en donde la auto-incompatibilidad ha sido demostrada. La andromonoecia es otro componente común de los sistemas reproductivos de las especies de *Zapoteca*; este fenómeno se interpreta como un medio para maximizar el uso de la energía reproductiva, sin reducir la atracción a los polinizadores. El número cromosómico básico de *Zapoteca* (x = 13), en asociación con algunos caracteres generalizados de las políades (ej., políades acalimadas, discoides, con 16 granos), reflejan relaciones entre *Zapoteca* y el resto de los géneros de la tribu Ingeae, con la excepción de *Calliandra* sensu stricto, género que es fuertemente atípico desde el punto de vista citológico y morfológico. En este trabajo se reconocen 17 especies en *Zapoteca*, de las cuales *Z. alinae*, *Z. andina* y *Z. tehuana* se describen aquí como nuevas para la ciencia. También se reconocen 11 subespecies, de las cuales *Z. portoricensis* subsp. *pubicarpa* se describe como nueva. En base a los patrones de variación en caracteres vegetativos (ej., número de pares de pinnas, número de pares de foliolos por pinna, tamaño de los foliolos, textura de los foliolos, patrones de vanación de los foliolos y tipo de estípulas) se propone una clasificación subgenérica, en donde las especies se agrupan en cuatro subgéneros distintos: *Nervosa*, *Zapoteca*, *Aculeata* y *Amazonica*.

Zapoteca (Leguminosae: Mimosoideae) is a genus of 17 species in the relatively specialized tribe Ingeae. Its species are mostly erect or scandent shrubs, of small to moderate size, found in vegetation types ranging from arid, scrubby thorn forests to wet, evergreen tropical forests, although most species occur in areas originally covered by tropical deciduous forests. *Zapoteca* ranges from southwestern United States and northern Mexico to the West Indies and southward through most of Mexico, Central America, and part of South America, to northern Argentina. It attains its greatest diversity in southern Mexico, although in some areas of Central America and the northern Andes diversity is also considerable.

Zapoteca was recently separated from the large genus *Calliandra* Benth. (Hernández, 1986a). Extensive analyses of the polyad characteristics, seedling morphology, chromosome numbers, and several reproductive features in *Calliandra* sensu Bentham revealed differential variation patterns among its neotropical species. These variation patterns were associated with two distinct taxonomic groups: the first, including the members of Bentham's series *Laetevirentes*, and the second, the remaining neotropical species, these belonging to series *Macrophyllae*, *Nitidae*, *Pedicellatae*, and *Racemosae*. The strongly divergent nature of these two groups, along with the absence of intermediate forms between them, suggested that *Calliandra*, as originally conceived by its author, is polyphyletic (Hernández, 1986a). In an accompanying paper Romeo (1986) provided supporting evidence based on differing patterns of nonprotein imino and sulphur amino acids in seeds and leaves of *Zapoteca* and *Calliandra*. Consequently, the new genus *Zapoteca* was proposed to include the species of series *Laetevirentes*. *Zapoteca* and *Calliandra* are compared in Table 1.

I consider all the species included by Bentham (1875) in *Calliandra* ser. *Laetevirentes* to be *Zapoteca*. When I originally proposed *Zapoteca* (Hernández, 1986a), the possibility of including *Calliandra amazonica* and *C. aculeata*, treated by Bentham in ser. *Macrophyllae*, was discussed. Since these two species share a number of reproductive characters with *Zapoteca* (i.e., compact, spherical, homomorphic capitula; 16-grained discoid polyads with lens-shaped thickenings; elastically dehiscent fruits with relatively thin valves), they are transferred in the present work to *Zapoteca*. The stipular spines of *Z. aculeata*, the compound pseudopanicles of *Z. amazonica*, and the small number and larger size of the leaflets in both species are interpreted as advanced characteristics. These species should not be considered by any means as intermediate between *Zapoteca* and *Calliandra*; they are specialized species within *Zapoteca*, with divergent morphological characters.

Zapoteca is defined by its compact, spherical, homomorphic capitula; acalymmate, 16-grained, discoid polyads with lens-shaped thickenings (excluding *Z. nervosa*); elastically dehiscent fruits with membranous or coriaceous valves; and basic chromosome number of x = 13. This combination of characters makes *Zapoteca* a well-circumscribed entity; however, with the exception of the distinctive circular thickenings in the polyads, each of these characters occurs independently in other genera of tribe Ingeae. The general characteristics of the *Zapoteca* polyads, its basic chromosome number, and some of its morphological characters reflect close relationships of this genus with some

TABLE 1. Comparison of *Zapoteca* and *Calliandra* (from Hernández, 1986a).

	Zapoteca	*Calliandra*
Leaflets	thin membranous, rarely coriaceous	chartaceous to coriaceous
Inflorescences	spherical heads; homomorphic	obconiform, racemose, rarely spherical; homomorphic or heteromorphic
Polyads	16-grained, discoid	8-grained, bisymmetric, with viscid appendage in "basal" grain
Stigmas	cup-shaped, with narrow area of polyad receptivity	expanded; discoid, or capitate
Pods	membranous to coriaceous	more rigid; coriaceous, ligneous, rarely membranous
Seedlings	cotyledons ovate, sessile, foliaceous, ephemeral	cotyledons sagittate, petiolate, fleshy, persistent
Chromosome numbers	$x = 13$	$n = 8, 11$

genera of the Ingeae, perhaps with members of the *Pithecellobium* complex; however, to establish definite generic affinities of *Zapoteca* is a difficult task due to our poor current understanding about generic delimitation within this complex. What seems clear is that *Zapoteca* has closer affinities with some of these genera than with *Calliandra* sensu stricto. Several characters in *Calliandra* (e.g., polyad features, chromosome numbers, floral morphology) are atypical in the tribe Ingeae and indicate that this genus is evolutionarily divergent from the other genera of the tribe.

This study provides an account of the morphology, biogeography, reproductive biology, cytogenetics, and taxonomy of *Zapoteca*. The taxonomic revision is based on over 4,000 herbarium specimens from the major collections of the world and on extensive field observations. Field studies were conducted in most of Mexico, Nicaragua, Costa Rica, and Panama during 1983–1985. In addition, individuals representing eight species and five subspecies of *Zapoteca* were grown from seed in a greenhouse at the Missouri Botanical Garden during 1982–1986; these plants provided information for the introductory chapters and served to complement the field observations and herbarium studies when taxonomic decisions had to be made. Based on the critical examination of correlated morphological characters, in combination with eco-geographical factors, I recognize 17 species and 11 subspecies in *Zapoteca* (Table 2). The species are classified into four subgenera, which represent different evolutionary lines.

THE PLANTS

VEGETATIVE MORPHOLOGY

Habit. The species of *Zapoteca* are relatively uniform in habit. Most are erect shrubs approximately 3–4 m tall with woody stems. In most cases the stems are rather thin (ca. 1–2 cm in diameter), although occasionally individuals of *Z. tetragona* and *Z. portoricensis* develop stems up to 20 cm in diameter. A few species are scandent or sub-

III. Subgenus *Aculeata*
  15. *Z. aculeata*

IV. Subgenus *Amazonica*
  16. *Z. microcephala*
  17. *Z. amazonica*

scandent. *Zapoteca portoricensis* subsp. *flavida* and *Z. amazonica* grow in moist thickets supported by neighboring shrubs. Similarly, *Z. caracasana* branches near the base of the primary stems and has spreading branches that become prostrate or subprostrate. The scandent and prostrate habits are found exclusively in warm, moist habitats.

Leaves. The leaves of all species of *Zapoteca* are stipulate and twice pinnate with opposite leaflets. The wide variation in leaf characteristics provides an excellent basis for classifying members of the genus. Mature leaflets vary in length from about 0.5 cm in *Z. alinae* and *Z. media* to a maximum of 22 cm in *Z. amazonica*. In addition, there is a clear tendency towards a reduction in number of leaflets concomitant with an increase in leaflet size. In all species of subg. *Zapoteca* the pinnae have from several to many pairs of leaflets; by contrast, in *Z. amazonica* the leaves have only one pair of pinnae with a single pair of large leaflets. Furthermore, all members of subg. *Zapoteca* have relatively membranous leaflets, whereas in the remaining species they are clearly chartaceous to coriaceous.

Extrafloral nectaries are uniformly present in *Z. filipes*, *Z. scutellifera*, and *Z. nervosa*. They are located between the insertion of the pinnae and, less frequently, between the distal pairs of leaflets. In *Z. scutellifera* and *Z. filipes* an additional nectary is located near the base of the petioles. The nectaries are more or less cup-shaped in *Z. scutellifera* and *Z. nervosa* and cylindrical in *Z. filipes*. According to Zimmerman's classification (Elias, 1983), all of these fall into the "Hochnektarien" category (elevated nectaries). Extrafloral nectaries have long been considered to be the focal point of a mutually beneficial relationship between the plants that possess them and certain groups of ants (see summary in Bentley, 1977). The ants exploit the nectar produced by these glands, which is rich in sugars, amino acids, proteins, and other compounds (Elias, 1983) and provide the plant with varying degrees of antiherbivore protection. However, such a relationship has not yet been demonstrated in *Zapoteca*.

Venation patterns. Despite the fact that leaves have numerous taxonomically useful characters, monographers generally limit themselves to superficial descriptions of the most conspicuous features of leaf architecture. In this section, I describe the venation pattern of the leaflets of several species of *Zapoteca*, in order to obtain a broad picture of the variation of this important component of the leaf architecture.

Mature leaflets of ten species of *Zapoteca*, representing all the subgenera (Table 3), were cleared following Dilcher (1974). The terminology follows Hickey (1973, 1977).

Variation in leaflet venation patterns is highly consistent with the subgeneric classification in *Zapoteca* and provides important information for phylogenetic interpretation. All members of the genus essentially have brochidodromous venation. The secondary veins usually depart from the primary vein at an acute to right angle, curving abruptly to join superadjacent secondaries to form a loop. In addition, loops are always enclosed by arches formed by higher-order veins. *Zapoteca nervosa* differs from the remaining examined species in having eucamptodromous venation in the basal half of each leaflet and brochidodromous venation in the upper half (Fig. 30). Furthermore, the tertiary domains in the leaflets of this species are elongate and parallel to the primary vein, and the free-ending veinlets are more abundant in the distal area and usually are once- or twice-branched.

The marginal venation is looped in all *Zapoteca* species with the exception of subg. *Amazonica*, where it is clearly fimbriated. Similarly, all species of the genus have incompletely closed areoles, except *Z. amazonica* and *Z. microcephala*, which have imperfectly developed areoles.

With the exception of *Z. tehuana*, all species of subg. *Zapoteca* are characterized by relatively fine, inconspicuous tertiary and higher-order veins that are difficult to discriminate even under a dissecting microscope. By contrast, leaflets of *Z. tehuana* and all species of the other subgenera (Table 3) have thicker and conspicuous tertiary and quaternary veins and free-ending veinlets. The venation patterns of *Z. tehuana* (subg. *Zapoteca*) and *Z. aculeata* (subg. *Aculeata*) are strikingly similar, reflecting taxonomic affinities between the two subgenera. These two species share the basic brochidodromous venation pattern of the genus; however, they differ in their marginal venation and in the orientation of their high-order veins and veinlets. Although the marginal venation of these two species is clearly looped, occasional free-ending marginal veins are present. The veinlets are characteristically oriented towards the admedial-basal area of the leaflets in these two species.

Zapoteca amazonica and *Z. microcephala* have several characters in their leaves that depart from the rest of the genus. The tendency towards the development of larger leaflets concomitant with a reduction in their number in these species is probably associated with an increase in the degree of organization of leaflet venation. Hickey (1977) pro-

TABLE 3. Characteristics of leaflet venation in *Zapoteca* species.

Taxon	Venation Type	Number of Primary Veins	Marginal Venation	Relative Thickness of Secondary and Tertiary Veins	Areole Development	Veinlets
Subgenus *Nervosa*	eucamptodromous basally and brochidodromous distally	1	looped	moderate	incompletely closed	1–2 branched
Subgenus *Zapoteca* (excluding *Z. tehuana*)	brochidodromous	1	looped	hairlike	incompletely closed	1–2 branched
Z. tehuana	brochidodromous	1	looped with free-ending veins	moderate	incompletely closed	admedially ramified dendroid
Subgenus *Aculeata*	brochidodromous	1	looped with free-ending veins	moderate	incompletely closed	admedially ramified dendroid
Subgenus *Amazonica*	brochidodromous	2	fimbriated	moderate	imperfect	dendroid

Material examined. Subgenus *Nervosa*: *Z. nervosa*, *Ekman 284*. Subgenus *Zapoteca*: *Z. formosa*, *H-959*, *H-210*, *H-230*, *H-217*; *Z. tehuana*, *H-950*; *Z. alinae*, *H-952*; *Z. mollis*, *Grayum 4201*; *Z. portoricensis*, *H-948*, *H-793*; *Z. tetragona*, *H-956*. Subgenus *Aculeata*: *Z. aculeata*, *Acosta 13599*. Subgenus *Amazonica*: *Z. amazonica*, *Woytkowski 5943*; *Z. microcephala*, *Haught 1711* (F). Collections in MO unless otherwise indicated.

posed a system of leaf classification based on increasing levels of regularity of venation (leaf ranks) which provides a useful scale here. The venation patterns of the two species of subg. *Amazonica* reflect an advanced condition because their tertiary veins have relatively regular courses (third rank; see Fig. 48). In contrast, the leaflets of the remaining species of *Zapoteca* fall in the second rank because their tertiary and higher-order veins are random in course and are usually not well differentiated from the lower orders. Of particular interest is the presence of two co-primary veins (Fig. 48) in the leaflets of *Z. amazonica* and *Z. microcephala*. This probably indicates leaflet fusion. Hickey & Wolfe (1975) reported that leaflet fusion is a common tendency in the Leguminosae.

Leaf pubescence. With few exceptions, pubescence type is not a reliable taxonomic character in *Zapoteca*, because in most of the species it is clearly variable within and between populations. *Zapoteca nervosa*, *Z. aculeata*, *Z. amazonica*, and *Z. microcephala* appear to be uniformly entirely glabrous or nearly glabrous, whereas *Z. mollis* is consistently pubescent throughout. In the remaining species of subg. *Zapoteca*, pubescence is variable, reaching an extreme of inconstancy in *Z. formosa* and *Z. portoricensis*. A microscopic survey of cleared leaflets of 13 of the species revealed three basic types of hairs (Figs. 1–4). Their taxonomic distribution is shown in Table 4 (terminology following Leelavathi & Ramayya, 1982).

(1) Unicellular conical hairs (Fig. 1) are the most abundant and are found at the base of leaflets and on the rachillas of *Z. aculeata*, along the leaflet margins of *Z. microcephala*, and on all leaf parts of all the pubescent species of subg. *Zapoteca*. A very similar type of hairs, unicellular clavate (Fig. 2), is occasionally found on the rachilla of *Z. alinae* (Table 4).

(2) Multicellular macroform conical hairs (Fig. 3) occur in all species of subg. *Zapoteca* except *Z. formosa* and *Z. alinae*. They are found, intermixed with other types of hair, primarily on leaflet margins and rachillas.

(3) Filiform capitate hairs and filiform clavate hairs (Fig. 4) usually have a uniseriate cylindrical foot formed by a variable number of cells of varied lengths, and a multiseriate (or rarely uniseriate?) head. These are usually restricted to leaflet margins and rachillas, and are found in all species of subg. *Zapoteca* except *Z. formosa*.

TABLE 4. Distribution of types of leaf trichomes in selected species of *Zapoteca*. Ia = unicellular conical, Ib = unicellular clavate; II = multicellular macroform conical, III = filiform capitate or filiform clavate. Relative abundance is indicated by: + = occasional, ++ = regular, +++ = abundant. All collections in MO unless otherwise indicated. H = author's collections.

Stipules. The stipules are persistent, leafy, and possess a series of veins running parallel to the margins (Figs. 5, 6); in most species the stipules are conspicuous (e.g., *Z. amazonica*, *Z. tetragona*), although in some they are very small (e.g., *Z. tehuana*). Exceptional in this respect is *Z. aculeata*, which has spinescent stipules (Fig. 46), and *Z. nervosa*, whose stipules are reduced to small (< 1 mm) scales. Throughout the genus the stipules are adpressed and probably have a protective function during the early phases of leaf and inflorescence development. *Zapoteca andina* is exceptional by having descending or depressed stipules (Fig. 41). Moreover all species have stipels at the base of the distal pairs of pinnae and at the distal tip of every pinna.

INFLORESCENCES AND FLOWERS

Inflorescences. The flowers are consistently arranged in compact, homomorphic, spherical, capitate inflorescences. In the basic plan of inflorescence organization, solitary or fasciculate peduncles are axillary and subtended by a leaf, as in *Z. alinae*, *Z. media*, and *Z. aculeata* (Fig. 7A). There is, however, an evolutionary trend toward the progressive reduction of the subtending leaves, which reaches its extreme in the two species of subg. *Amazonica*, where the leaves are always vestigial, and the inflorescence therefore appears to be an elongate panicle (Fig. 7D, E). Transitional forms between the two extremes are found in several species of subg. *Zapoteca* (Fig. 7B). For instance, in *Z. mollis*, *Z. portoricensis*, and additional species, the subtending leaves start developing during or after anthesis. Sometimes, however, the subtending leaves never develop, as in some individuals of *Z. caracasana* (Fig. 7C) and *Z. formosa*, in which the capitula are apparently aggregated in paniclelike inflorescences.

The trend towards retardation and suppression of leaf development that results in differences in foliation among the species of *Zapoteca* has also produced various patterns of inflorescence organization. I interpret these types as steps in a continuum of inflorescence specialization rather than as discrete and fundamentally different types. An indication of the derived character of the "paniculate" inflorescences of *Z. microcephala*, *Z. ama-*

zonica, and other species in subg. *Zapoteca* is the presence of persistent paired stipules at every node along the flowering system. These inflorescence types, therefore, cannot be considered strictly paniculate, and for this reason the term "pseudopanicle" will be used.

In summary, there has been an evolutionary trend of inflorescence modification in *Zapoteca*, where retardation and suppression of the subtending leaves has played a prominent role in changing the overall aspect of the flowering system. The axillary capitula subtended by a developed leaf

(leafy, axillary capitula) appear to represent the basic pattern. The paniclelike inflorescences of *Z. microcephala* and, especially, *Z. amazonica* (subg. *Amazonica*) are highly modified and are clearly derived from the basic type. Intermediate types exist in many species of subg. *Zapoteca*, where a single individual may have both leafy, axillary capitula and flowering branches with vestigial or late-developing subtending leaves.

Flowers. Aside from variation in size and in the relative proportions of their parts, the flowers of *Zapoteca* species are extremely constant. Details of floral morphology and certain aspects of floral biology are in the generic and specific descriptions and in the section on reproductive biology.

POLLEN

The diversity of pollen types in subfamily Mimosoideae has been studied extensively by several authors (Guinet, 1969, 1981—a review; Sorsa, 1969; Niezgoda et al., 1983). One of the outstanding features in this subfamily is the high frequency of permanently compound grains, these either in tetrads or more commonly in polyads. As Guinet (1981) and others pointed out, the basic polyad type in the Mimosoideae is the acalymmate type, in which the individual grains are more or less free from one another. This form of polyad cohesion is in contrast to the calymmate type, where the external layer of the exine is common to all cells. Calymmate polyads are found in *Calliandra*.

As discussed elsewhere (Hernández, 1986a), several comprehensive surveys on the pollen characteristics of *Calliandra* (Guinet, 1965, 1969, 1981; Guinet & Barth, 1969; Sorsa, 1969; Niezgoda et al., 1983) indicate the phyletic distinctness of *Zapoteca*. The basic plan of polyad organization here is the same as that in the other genera of tribe Ingeae, but unlike that of *Calliandra* sensu stricto. All the species in the genus have acalymmate, discoid, radially symmetrical, 16-grained polyads (Figs. 8–13). The eight central grains, which are distributed in two rows, are morphologically different from the peripheral grains (i.e., the pollen grains exhibit heteromorphy). The external layer of the exine has an undifferentiated granular structure, and the individual grains have internal apertures (see fig. 7 in Niezgoda et al., 1983). The size of the polyads ranges from 76 to 141 μm. One very striking diagnostic character, found nowhere else in Mimosoideae, is the occurrence of prominent lens-shaped structures in the central cells on one side of the polyad. These are found in all species of *Zapoteca* except *Z. nervosa*. In connection with this, Guinet (pers. comm., 1985) observed that the rounded lens-shaped areas occur on both sides of the polyads (on eight grains) in *Z. aculeata* and *Z. amazonica*; nevertheless, they are less pronounced on one side. Such areas sometimes occur on some or all of the peripheral grains of *Z. alinae* polyads (Fig. 9).

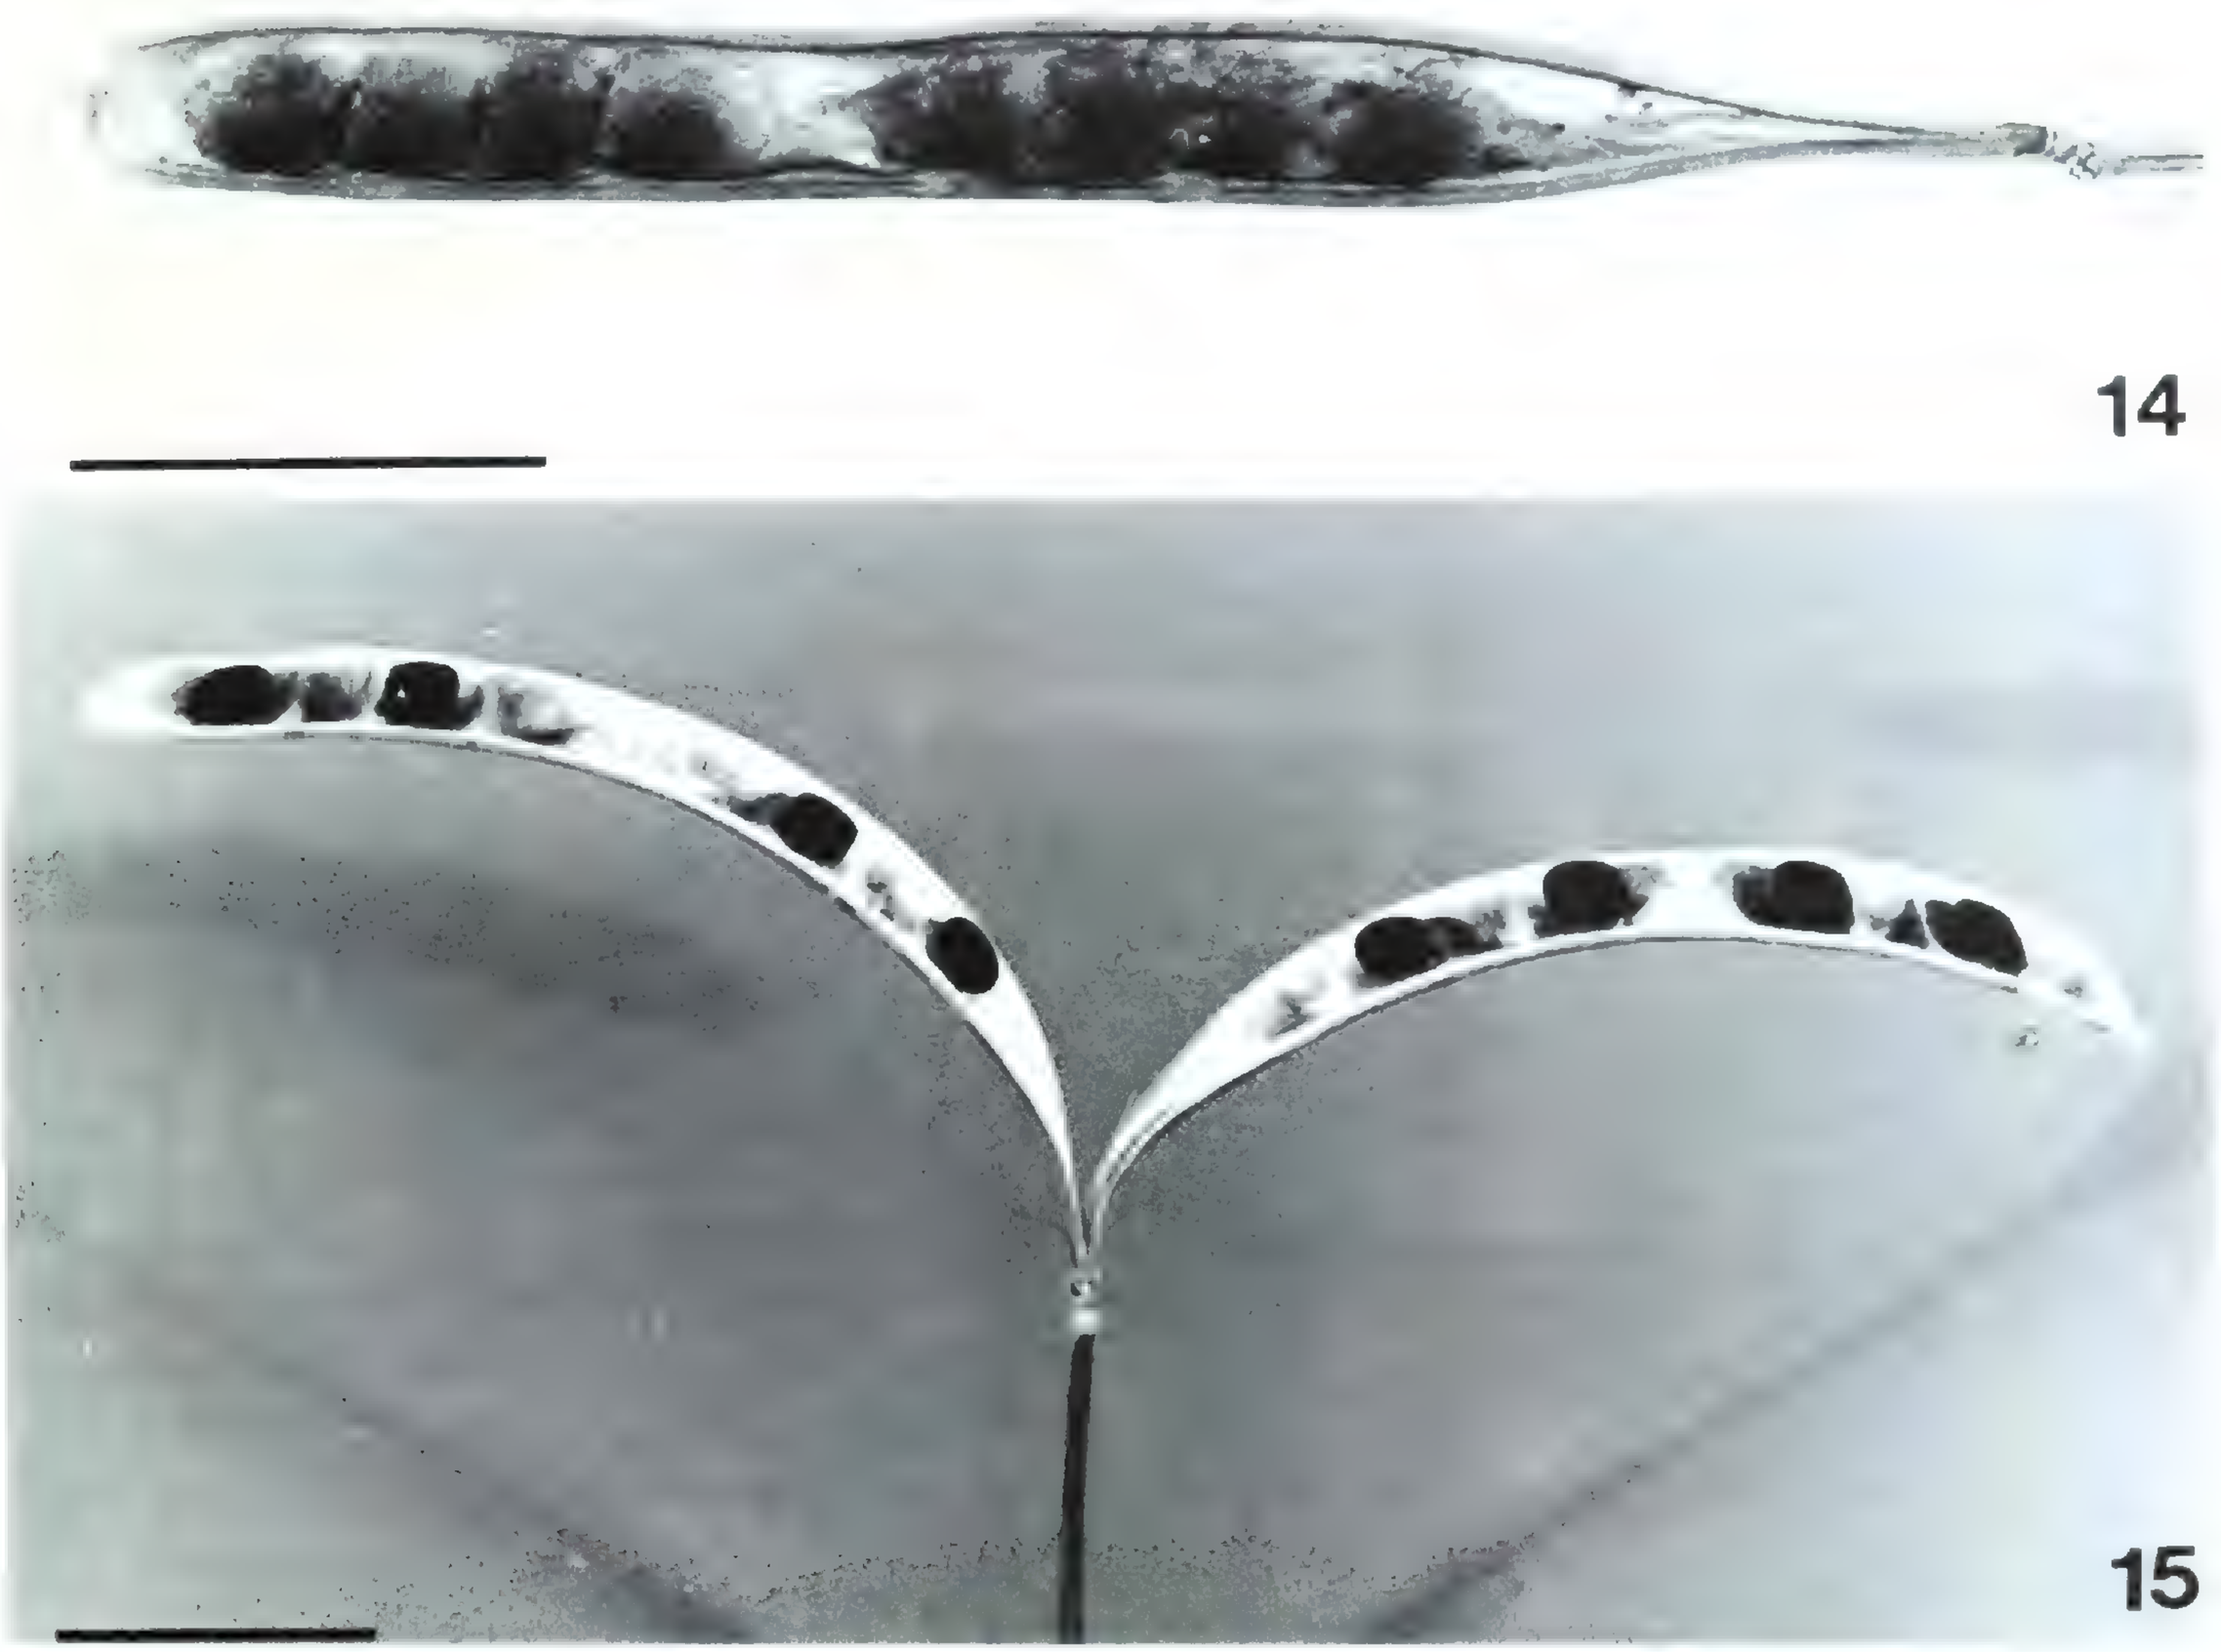
PODS, SEEDS, AND SEED DISPERSAL

Pods. Pod morphology is relatively constant throughout *Zapoteca* (Figs. 14, 15). The pods are usually straight, linear, and flattened; they generally have unconstricted margins, visible seed chambers, and thickened sutures (terminology following Gunn, 1984). Pod size varies from 3.5 × 0.7 cm in *Z. formosa* subsp. *mollis* to 24 × 1.2 cm in *Z. amazonica*. There is some interspecific variation in the texture (density) of the valves, which is of taxonomic value. In this respect, the species may be arranged into three groups: 1) *Z. lambertiana* and *Z. filipes* with thin, membranous valves; 2) the remaining species of subg. *Zapoteca*, along with *Z. nervosa*, with thick, membranous valves; and 3) *Z. aculeata*, *Z. microcephala*, and *Z. amazonica*, with coriaceous valves. It is important to mention that the terminology of pod texture used here is relative, and as such its use is not applicable to other structures (e.g., leaflets). The pods are glabrous except those of *Z. caracasana* subsp. *weberbaueri*, *Z. mollis*, *Z. portoricensis* subsp. *pubicarpa*, and *Z. formosa* subsp. *salvadorensis*, which are short-pubescent, densely villous, puberulent, and pilose to densely pilose respectively.

Seeds. In all species of subg. *Zapoteca*, the seeds are widely ovoid to rhomboid and compressed and lack rupture lines, arils, or wings (Figs. 16, 17). In most members of this subgenus the testa is mottled, or dichrome, in which case the area encompassed by the pleurogram (areola) has a lighter color than the outside area. There is considerable interpopulational variability in seed size and the coloration of the testa, especially in *Z. formosa*; by contrast, *Z. tetragona* appears to be consistent in having dark, monochrome, ovate seeds. Another seed feature is the pleurogram, common in subfamily Mimosoideae (Gunn, 1984). Seeds of subg. *Zapoteca* usually have irregular, 90° pleurograms (sensu Gunn, 1984), although those of *Z. tetragona* are always regular. The seeds of *Z. amazonica* differ from those of subg. *Zapoteca* in being narrowly rhomboid to narrowly elliptic, larger, and in lacking the characteristic pleurogram.

Hernández 206*); one of the peripheral grains has the lens-shaped structure characteristic of the central grains. — 10. *Z. lambertiana* (*H. Hernández 147*). — 11. *Z. tehuana* (*H. Hernández 950*). — 12. *Z. tetragona* (*H. Hernández 956*). 13. *Z. caracasana* subsp. *weberbaueri* (*Johnson 2494*, MO); both sides of the polyad are shown. All collections at MEXU unless otherwise indicated. Scale bars = 10 μm Figures 8 10; 50 μm Figures 11–13.

Seed dispersal. *Zapoteca* pods dehisce explosively with the valves splitting along both sutures from apex to base (Fig. 15). This is probably the prevalent short-range dispersal mechanism for species of *Zapoteca* over land and is probably effective over larger distances as a result of accumulative short-distance dispersal events over many generations.



FIGURES 14, 15. Pods of *Zapoteca tetragona* (*H. Hernández 956*).—14. Indehisced pod.—15. Dehisced pod. Scale bars = 2 cm.

This dispersal mechanism, however, does not explain the presence of species such as *Z. formosa*, *Z. caracasana*, and *Z. portoricensis* on islands, which they presumably reached by long-distance dispersal over water. *Zapoteca formosa*, for instance, occurs throughout the West Indies and on some islands off the Mexican Pacific coast (Revillagigedo Islands). Populations of this variable species frequently grow in coastal areas. Although experiments have shown that seeds and mature pods of *Z. formosa* subsp. *formosa* taken from a coastal population of the Yucatán Peninsula floated for only two to four days in seawater, the seeds are highly resistant to saline water. As shown in Figure 18, seeds from this population (*Hernández 946*) germinated after soaking in saline water (3.4% sodium chloride) for up to 70 days. Most of the seeds germinated normally when they were mechanically scarified and transferred to petri dishes in a medium moistened with fresh water. Ridley (1930) presented evidence that seeds and pods may disperse for considerable distances floating on debris. The great resistance to salinity of the seeds of *Z. formosa*, and presumably of *Z. caracasana* and *Z. portoricensis* as well, suggest that these species dispersed by flotation from the continental mainland. Further discussion about the distribution and dispersal of *Z. formosa* is provided below.

SEEDLINGS

The taxonomic importance of seedling characters has been recognized by legume researchers for a long time (De Candolle, 1825; Compton, 1912). Recently, such characters have been applied successfully in the construction of generic and infrageneric classifications in Leguminosae (Léonard, 1957; Vassal, 1969; Robbertse & van der Schiff, 1971; Kupicha, 1977; Guinet et al., 1980; and others). The distinctive seedlings of the species formerly assigned to ser. *Laetevirentes* indicated the heterogeneous nature of *Calliandra*

FIGURES 16, 17. Seeds of *Zapoteca* species showing the irregular pleurograms.—16. *Z. portoricensis* subsp. *portoricensis* (*H. Hernández 948*).—17. *Z. formosa* (*Torres 4063*). Collections at MEXU and MO. Scale bars = 500 μm.

(sensu Bentham) and provided evidence for recognition of *Zapoteca* (Hernández, 1986a).

Seedlings of 19 populations representing eight species of *Zapoteca*, all belonging to subg. *Zapoteca*, were studied (Table 5). About 10 mechanically scarified seeds per sample were germinated in petri dishes. After one to three days, when the radicles had emerged, the germinated seeds were transferred to individual pots. The seedlings were described following Duke & Polhill (1981).

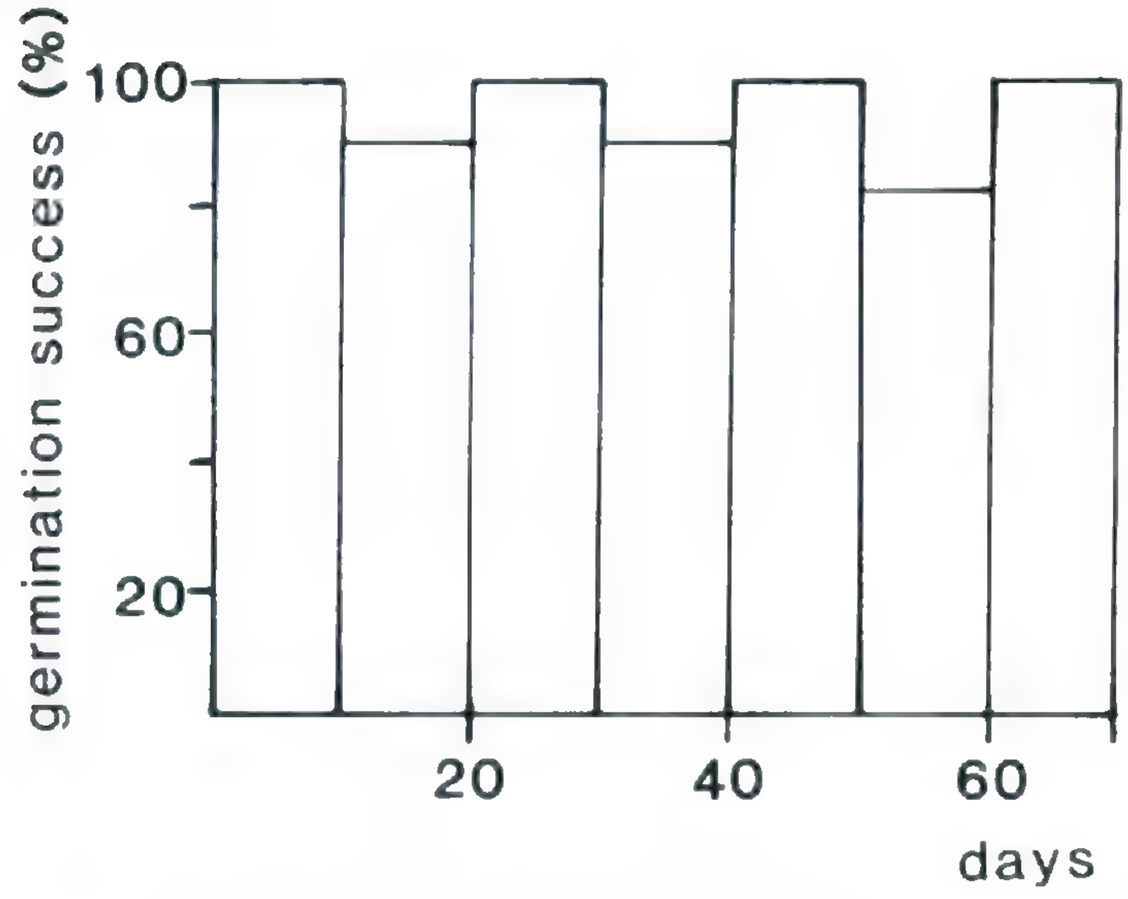


FIGURE 18. Resistance of *Zapoteca formosa* subsp. *formosa* seeds to saline water (3.4% sodium chloride). The bars indicate percent of germinated seeds. Ten seeds were tested at each time interval.

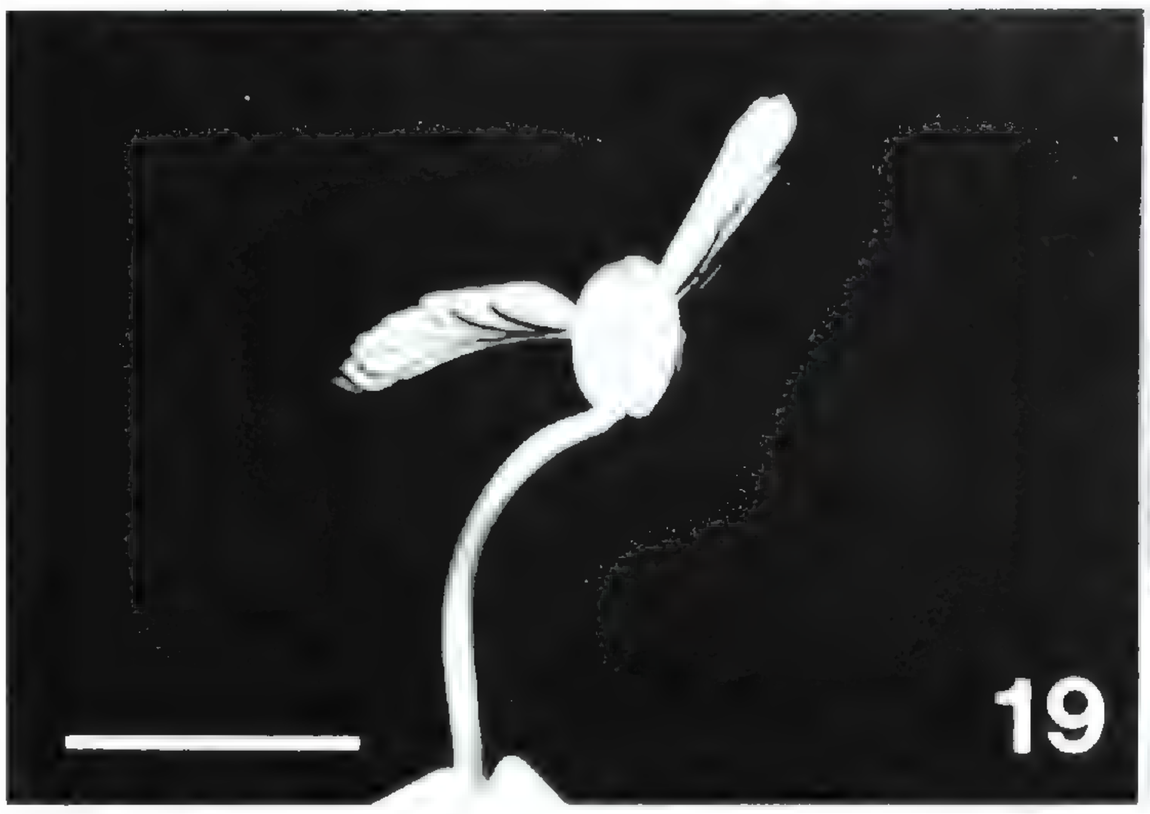
The principal characters used in the descriptions were: 1) position (whether epigeal, geal, or hypogeal), morphology, texture, and degree of persistence of the cotyledons, and 2) type (whether pinnate or bipinnate) and sequence (whether opposite or alternate) of the eophylls.

These samples were remarkably uniform, the seedlings of each species examined being essentially identical. Diagnostic characters at the species level, such as the square stems of *Z. tetragona* or the ovate leaflets of *Z. formosa*, became manifest above the third eophyll, as the first metaphylls arose. A brief description of the seedlings listed in Table 5 follows (Figs. 19, 20):

Germination phaneroepigeal; cataphylls absent. Cotyledons sessile, elliptic to elliptic-ovate, foliaceous, ephemeral (remaining functional for ca. one week). Leaves stipulate, glabrous; first two eophylls opposite and pinnate, the pinnae with 4–12 lanceolate to narrowly oblong leaflets; third eophyll alternate, bipinnate, with 1 pair of pinnae; fourth eophyll alternate, bipinnate, with 1, rarely 2 pairs of pinnae.

In summary, although the seedlings of subg. *Aculeata*, *Amazonica*, and *Vervosa* remain unknown, the seedlings that have been observed so far, all in subg. *Zapoteca*, display a high degree of inter- and intraspecific morphological homogeneity.



FIGURES 19, 20. Seedlings of *Zapoteca*. —19. Five-day-old seedling of *Z. tetragona* (*H. Hernández 956*). 20. Three-week-old seedling of *Z. portoricensis* subsp. *portoricensis* (*H. Hernández 948*). Collections at MEXU and MO. Scale bars = 1 cm.

PATTERNS OR MORPHOLOGICAL DIFFERENTIATION

There are several morphological features common to all *Zapoteca* species. Among the most important are: brochidodromous venation patterns in leaflets; persistent, leafy stipules (excluding *Z. aculeata*); homomorphic, spherical, capitate inflorescences; cup-shaped stigmas; 16-grained polyads with prominent lens-shaped thickenings (excluding *Z. nervosa*); and dry, linear, flattened pods with thickened margins and showing a particular mode of dehiscence.

The distribution of morphological features among the species of *Zapoteca* reflects four evolutionary lines, which correspond to the four subgenera proposed in the systematic treatment.

Subgenus *Nervosa* comprises *Z. nervosa*, which appears to be morphologically the most isolated species in the genus. Superficially, this species appears out of place within *Zapoteca*; however, the morphology and the type of dehiscence of its pods and the overall features of its inflorescences justify its placement within this genus.

Zapoteca nervosa exhibits several characters unique in the genus, the most important of which are: stems with fissured bark; large, coriaceous, grayish leaflets with a peculiar eucamptodromous brochidodromous venation; and 16-grained polyads

TABLE 5. Species of *Zapoteca* in which seedlings were studied. H = author's collections.

Taxon	Collection Data	Distribution
Z. alinae	*Torres 3947* (MO, MEXU)	Mexico, Oaxaca

Z. tetragona	*Johnson 1582* (MO)	Mexico, Veracruz

without lens-shaped structures. In this connection, it is reasonable to hypothesize that *Z. nervosa* represents an evolutionary line that separated from the main stock early in the evolution of the genus, and its peculiar morphological features would be explained by divergent evolution. The lack of areolate, lens-shaped thickenings in the polyads of *Z. nervosa*, a character also absent in the remaining genera of the Ingeae, appear to represent a primitive condition within *Zapoteca* and suggests that this species is phylogenetically basal in this genus. Additional information on this critical species is needed in order to learn more about its phylogenetic relationships.

Subgenus *Zapoteca* is the most widespread and diversified subgenus in *Zapoteca*. Yet a number of morphological features common to all the species make this subgenus easily recognizable. All the species have pinnae with several to many pairs of thin, membranous leaflets, which show characteristic usually inconspicuous and simplified venation patterns. The highest diversity of hair types (three types) of the genus is found in subg. *Zapoteca*; the species of the remaining subgenera are characterized by having only the unicellular conical type (Table 4). Further, the valves in the pods in subg. *Zapoteca*, along with *Z. nervosa*, are consistently thick-membranous, whereas those of subg. *Aculeata* and *Amazonica* are coriaceous.

The pattern of leaflet venation in *Z. tehuana* differs from those of the other species in subg. *Zapoteca* and shows strong similarity with those of *Z. aculeata* (subg. *Aculeata*). This may indicate a phylogenetic link between the two subgenera.

Subgenus *Aculeata* contains only *Zapoteca aculeata*, which is characterized primarily by spinescent stipules (a characteristic that has clearly been derived within the genus), by an apparent arborescent habit, and by pinnae having fewer pairs of chartaceous-coriaceous leaflets than those of subg. *Zapoteca*. The coriaceous pods of *Z. aculeata* resemble those of subg. *Amazonica*.

Subgenus *Amazonica* is made up of *Z. amazonica* and *Z. microcephala*, which are characterized by having the most obvious combination of apomorphic features in *Zapoteca*. Their leaves are reduced to two or three large, coriaceous leaflets in each pinna. This is the result of an evolutionary trend toward reduction in the number of leaflets associated with increased leaflet size. This trend is also seen in other genera of Mimosoideae (e.g., *Calliandra*, *Mimosa*). Moreover, the leaflets in these species have a number of common architectural features reflecting an increased level of organization, which is also interpreted as an advanced condition. A progressive trend toward suppression of leaves subtending the inflorescence in *Zapoteca* has resulted in the highly specialized, elongate pseudopanicles of these species. Among other clearly apomorphic features of subg. *Amazonica* are the elongate seeds of *Z. amazonica*, which lack the characteristic pleurogram and are the largest in the genus.

Biogeography

Zapoteca ranges from the southwestern United States (southern Arizona and southwestern Texas) and northern Mexico, from about latitude 32°30′N, southward through most of Mexico, Central America, and much of South America (Venezuela, Colombia, Ecuador, Peru, Bolivia, Guyana, Brazil, Paraguay) to northern Argentina (ca. latitude 27°30′S). *Zapoteca* also occurs on most of the West Indies and in the Revillagigedo Islands (i.e., Isla Socorro and Isla Clarión).

Zapoteca species occur in a variety of environments, ranging from open, arid or semiarid, scrubby vegetation types (e.g., *Z. media*, *Z. alinae*, *Z. formosa* subsp. *mollicula*, and *Z. formosa* subsp. *schottii*) to the wet evergreen forests of Amazonian Peru (*Z. amazonica*). Most populations of *Z. portoricensis* subsp. *flavida* and *Z. tetragona* are found in relatively wet, lowland habitats, generally on disturbed sites. The greatest degree of diversification has occurred in areas covered by seasonal, tropical deciduous forests (sensu Breedlove, 1981). In addition to the species found in clearly arid regions, most populations of eight species of *Zapoteca* (*Z. nervosa*, *Z. lambertiana*, *Z. filipes*, *Z. mollis*, *Z. caracasana*, *Z. andina*, *Z. formosa*, and *Z. tehuana*) occur in tropical deciduous forests. In addition, *Z. portoricensis* subsp. *portoricensis* and subsp. *pubicarpa* primarily occur in middle-elevation oak, pine–oak, or subtropical montane moist forests.

The occurrence of three of the four subgenera of *Zapoteca* in South America (*Zapoteca*, *Aculeata*, and *Amazonica*), compared with only one in Mexico and Central America, is probably a consequence of the more ancient existence of *Zapoteca* in South America. Although only subg. *Zapoteca* is represented in Mexico and Central America, extensive diversification has taken place at the specific and subspecific levels, especially in Mexico. For instance, there are seven subspecific taxa in Mexico (i.e., *Z. portoricensis* subsp. *portoricensis*, *Z. portoricensis* subsp. *pubicarpa*, *Z.*

portoricensis subsp. *flavida*, *Z. formosa* subsp. *formosa*, *Z. formosa* subsp. *rosei*, *Z. formosa* subsp. *mollicula*, *Z. formosa* subsp. *schottii*), four of them restricted to this country. In contrast, only four subspecies of subg. *Zapoteca* occur in all of South America (*Z. portoricensis* subsp. *flavida*, *Z. caracasana* subsp. *caracasana*, *Z. caracasana* subsp. *weberbaueri*, and *Z. formosa* subsp. *formosa*), and only one of these, *Z. caracasana* subsp. *weberbaueri*, is endemic.

Viewed from a global perspective, there are no clear centers of species diversity in *Zapoteca*. The total number of species and the number of endemic species are roughly correlated with the size of each region (i.e., Mexico, 7 species/4 endemics; Central America, 6/2; West Indies, 4 1; and South America, 10/6. However, a more detailed analysis of the areas of species concentration and the distribution of endemic taxa revealed several regions with high diversity (Fig. 21).

Southern Mexico (Oaxaca and Chiapas, including southern Puebla) has the largest concentration of species and subspecies of *Zapoteca*. This relatively small region, characterized by its remarkable climatic and topographic diversity, contains seven species, and if subspecies are taken into account, the figure rises to eleven taxa (*Z. media*, *Z. alinae*, *Z. lambertiana*, *Z. portoricensis* subsp. *portoricensis*, *Z. portoricensis* subsp. *pubicarpa*, *Z. portoricensis* subsp. *flavida*, *Z. tetragona*, *Z. formosa* subsp. *formosa*, *Z. formosa* subsp. *rosei*, *Z. formosa* subsp. *mollicula*, and *Z. tehuana*). Four of these are endemics (*Z. alinae*, *Z. portoricensis* subsp. *pubicarpa*, *Z. formosa* subsp. *mollicula*, and *Z. tehuana*), especially to dry areas of Oaxaca and the arid valleys of the Pueblan–Oaxacan border region. The number of species and subspecies of *Zapoteca* suddenly decreases from this center in all directions (Fig. 21). On the Pacific slope of Mexico, from Guerrero northwards, there are four taxa (*Z. tetragona*, *Z. formosa* subsp. *formosa*, *Z. formosa* subsp. *rosei*, and *Z. formosa* subsp. *schottii*), decreasing to one in the northern portion. *Zapoteca media* and *Z. formosa* subsp. *formosa* are the only taxa that occur in the Central Plateau. Along the entire Atlantic slope, from Tabasco to Tamaulipas, together with the Yucatán Peninsula, there are only five taxa (*Z. lambertiana*, *Z. portoricensis* subsp. *portoricensis*, *Z. portoricensis* subsp. *flavida*, *Z. tetragona*, and *Z. formosa* subsp. *formosa*). *Zapoteca lambertiana* is the only one of these that is essentially endemic to this region.

In Central America, there are a total of eight taxa (*Zapoteca portoricensis* subsp. *portoricensis*, *Z. portoricensis* subsp. *flavida*, *Z. mollis*, *Z. caracasana*, *Z. tetragona*, *Z. costaricensis*, *Z. formosa* subsp. *formosa*, and *Z. formosa* subsp. *salvadorensis*). Diversity is quite uniform among the different countries (Fig. 21). *Zapoteca mollis* and *Z. costaricensis* are essentially endemic to Costa Rica, although a disjunct population of the former is known from Panama. *Zapoteca formosa* subsp. *salvadorensis* is restricted to southern Guatemala and El Salvador.

Six taxa of *Zapoteca* occur in the West Indies (*Z. nervosa*, *Z. portoricensis* subsp. *portoricensis*, *Z. portoricensis* subsp. *flavida*, *Z. caracasana* subsp. *caracasana*, *Z. formosa* subsp. *formosa*, and *Z. formosa* subsp. *gracilis*). Generally only a single species occurs on a particular island; however, in Hispaniola the four species, including the endemic and morphologically distinct *Z. nervosa*, occur together. Howard (1973) pointed out that Hispaniola and Cuba are the most floristically diverse islands in the West Indies and that they show great habitat diversity and highest percentage of endemism (Hispaniola with 33% of endemic genera). *Zapoteca formosa* subsp. *gracilis* is the second endemic entity in the West Indies. It is primarily restricted to coastal areas in Cuba, the Bahamas, Cayman Islands, and northwestern Haiti.

Eleven taxa of *Zapoteca* occur in South America. The greatest diversity occurs in the tropical Andean countries, Venezuela, Colombia, Ecuador, Peru, and Bolivia, where populations are primarily found in the foothills of the Andes, in the inter-Andean valleys, and less commonly in the Amazon Basin. As illustrated in Figure 21, the number of taxa in each of these countries ranges from four to six, with Colombia and Ecuador most diverse. Perhaps the most remarkable biogeographical feature of this whole area is the occurrence of five endemic taxa, which, excluding *Z. caracasana* subsp. *weberbaueri* and *Z. andina*, comprise the most highly advanced species in *Zapoteca*, each with a large number of derived morphological characters (i.e., *Z. aculeata*, Ecuadorean Andes; *Z. microcephala*, Median Valley of the Magdalena River; and *Z. amazonica*, Amazonian Peru). Outside this area, diversity is much lower, with one or two taxa occurring within Guyana, Brazil, Paraguay, and northern Argentina (Fig. 21). Within this large region, however, there are two extra-Andean endemic species: *Z. filipes*, restricted to the Brazilian states of Goiás and Minas Gerais, and *Z. scutellifera*, found in the states of Amazonas, Pará and Rondônia, Brazil, and in the departments of El Beni and Santa Cruz, Bolivia.

Zapoteca species are predominantly segregated geographically and/or ecologically, although a

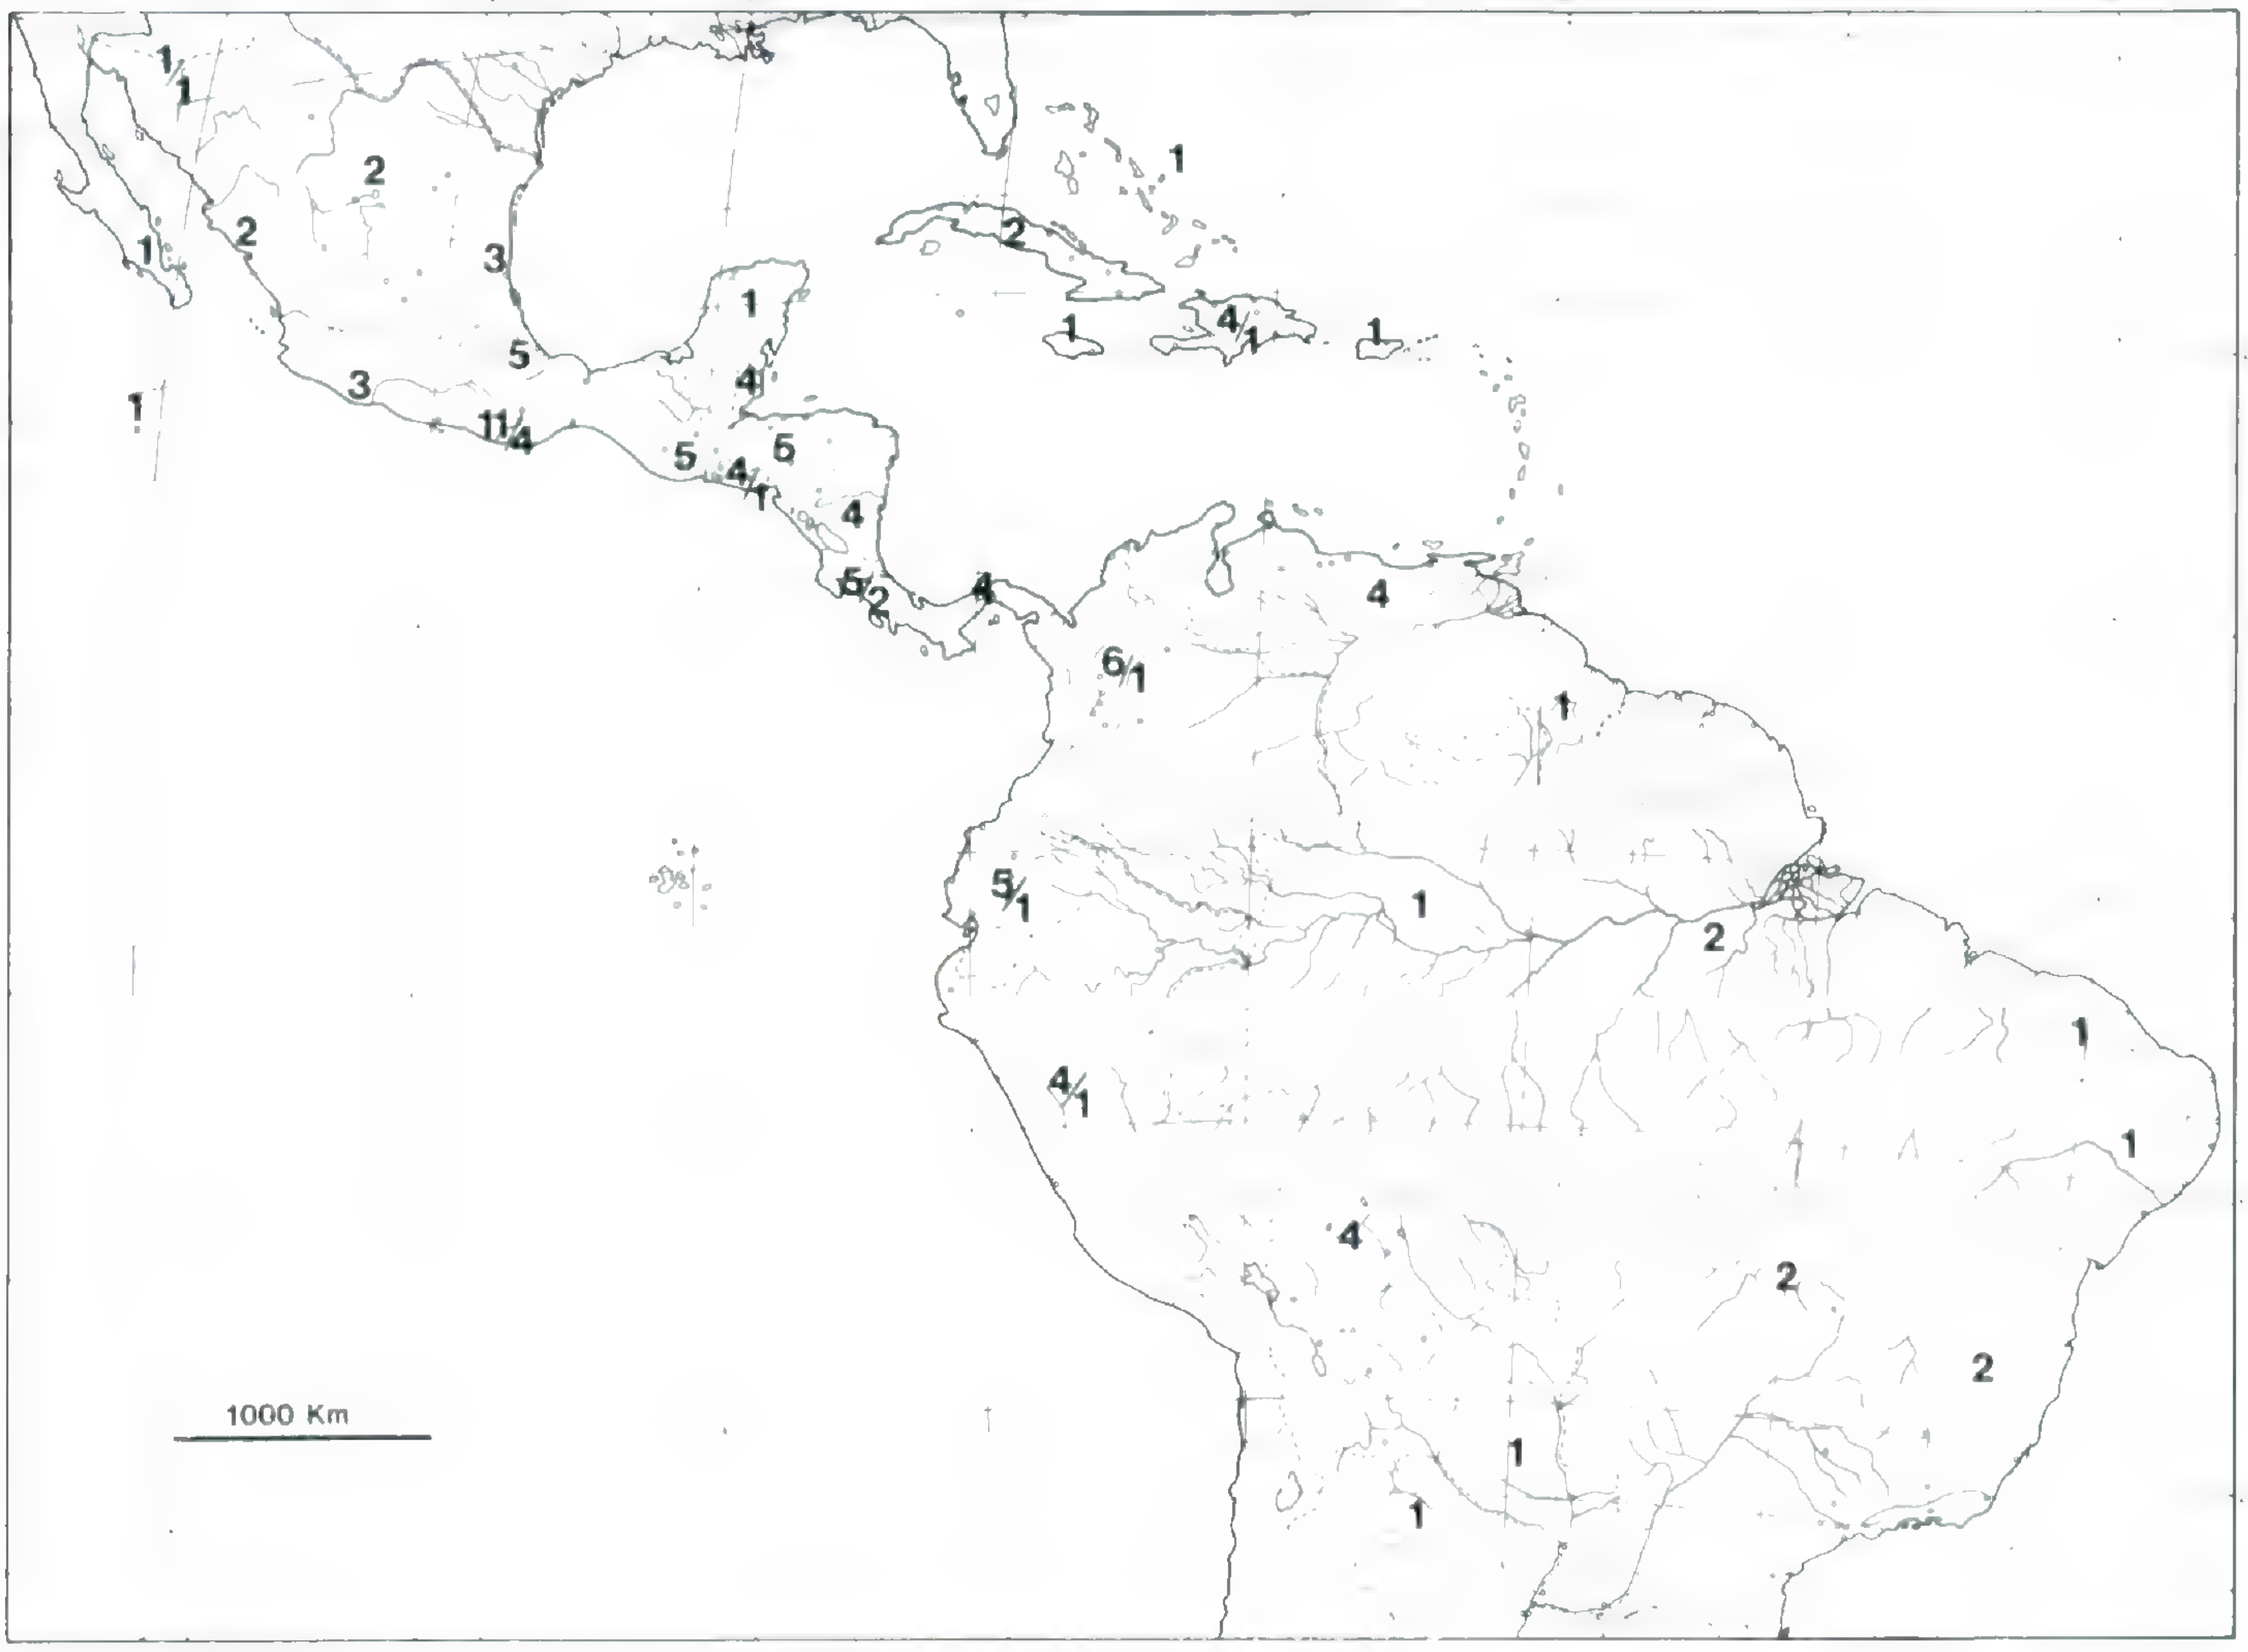

FIGURE 21. Number of *Zapoteca* species and subspecies per country. Mexican regions and Brazilian states are treated as separate units. Total number of taxa/endemic taxa.

number of cases of gross geographical overlap are known. However, only a few records of true sympatry exist: in the District of Tlacolula, Oaxaca, plants of *Z. alinae* (*H. Hernández & Ramírez 942*) have been found intermixed with plants of *Z. formosa* subsp. *rosei* (*H. Hernández & Ramírez 943*); in this same area of Oaxaca, *Z. formosa* subsp. *formosa* has occasionally been found growing alongside *Z. formosa* subsp. *rosei* (*H. Hernández & Torres 216*, *217* and *Magallanes 111*, *113*). Also, in the tropical deciduous forest of El Chorreadero, Chiapas, *Z. lambertiana* (*Breedlove 39694*, *H. Hernández & Ramírez 891*) and *Z. portoricensis* subsp. *portoricensis* (*Breedlove 11889*) have been collected; however, it is unclear whether these are narrowly sympatric.

There are some presumed hybrids. For example, in southern Guatemala and in southern Mexico, a number of collections provide evidence for extensive hybridization between *Z. portoricensis* subsp. *portoricensis* and *Z. tetragona*; in southern Puebla and northern Oaxaca, some plants with characters intermediate between *Z. media* and *Z. formosa* likewise suggest hybridization. In Guerrero populations of *Z. formosa* subsp. *formosa* and *Z. formosa* subsp. *rosei* come into close proximity, and there are a number of collections of probable hybrid origin.

The predominance of allopatric distributions and the apparent rarity of hybrids in *Zapoteca* suggest that hybridization has played an insignificant role in the evolution of the genus. The few cases of strict sympatry may represent secondary contact of previously differentiated populations. It could be hypothesized that speciation in *Zapoteca* has primarily resulted from genetic differentiation of geographically isolated populations.

There are wide disjunctions in the distribution of *Z. formosa* subsp. *formosa* in South America, from northern Colombia and Venezuela to Bolivia, southeastern Brazil, and Paraguay (Fig. 44). As elaborated below, its distribution was probably continuous across the Amazon Basin during the cool-dry phases of the Pleistocene, when a drier and presumably more suitable environment for this subspecies was widespread (Ab'Sáber, 1982; Absy, 1982; Bigarella & Andrade-Lima, 1982; van der Hammen, 1982; Prance, 1982). *Zapoteca scu-*

tellifera is closely related and is known from a few disjunct populations in the Amazon Basin (Fig. 44). Specialized characters in *Z. scutellifera* (e.g., scutelliform extrafloral nectaries, scandent habit) and its presumed edaphic specialization suggest that it was probably derived from *Z. formosa* subsp. *formosa*. *Zapoteca scutellifera* could have been derived from populations of *Z. formosa* subsp. *formosa* that became isolated after the return to the present-day, warm-wet climatic conditions.

This pattern, along with the patchy distributions of dry-forest species like *Z. lambertiana* and *Z. mollis*, supports Gentry's (1979, 1982) theory of reverse refuges. This theory assumes that the present discontinuities in the distribution of the dry forests (dry forest refuges) coupled with the existence of geographically restricted, morphologically differentiated dry-area populations, result from a shift towards more mesic conditions after the climatic deterioration in the Quaternary.

A second example of possible allopatric speciation in *Zapoteca* involves the two members of the highly specialized subg. *Amazonica*: *Z. microcephala* and *Z. amazonica*. *Zapoteca microcephala* is restricted to the Middle Magdalena River Valley, whereas *Z. amazonica* occurs in Amazonian Peru (Fig. 47). These two species, which are obviously closely related, probably differentiated as a consequence of a vicariance event caused by the uplift of the northern Andes, which reached their present elevation at the beginning of the Pleistocene some three million years ago (van der Hammen, 1982).

Additional evidence suggesting an allopatric model of speciation for *Zapoteca* is the relatively common occurrence of closely related taxa displaying contiguous or nearly contiguous distributions. This distribution pattern is shown by closely related species, such as *Z. tetragona* and *Z. andina* (Figs. 40, 42), and by virtually all the subspecies in the genus (Figs. 36, 39, 41).

Reproductive Biology

During the past few years a considerable body of data has accumulated on the diverse reproductive mechanisms of the Mimosoideae (Simpson et al., 1977; Kenrick & Knox, 1982; Koptur, 1983, 1984; Knox & Kenrick, 1983; Hopkins, 1984; Bernhardt, 1983). Entomophily was probably the original mode of pollination in the subfamily, as indicated by the presence of apparently insect, probably hymenopteran, pollinated mimosoid inflorescences in the Middle Eocene Claiborne Formation, Tennessee (Crepet & Dilcher, 1977), and in the Oligocene of the Texas Gulf Coast (Daghlian et al., 1980), and also by the wide distribution of this pollination system in the subfamily. It has been suggested (Raven & Polhill, 1981; Polhill et al., 1981) that Mimosoideae were already differentiated from the other subfamilies by the start of the Eocene (54 m.y. B.P.). Entomophily is widespread in tribe Mimoseae (e.g., *Desmanthus*, *Leucaena*, *Mimosa*, *Prosopis*), which is generally considered to be the basal tribe of the Mimosoideae. Furthermore, most species of *Acacia* (Acacieae) are insect-pollinated (Bernhardt, 1983; pers. obs.); however, bird pollination has been derived secondarily in some Australian species of this genus (Ford & Forde, 1976; Bernhardt, 1983; Kenrick et al., 1983). In contrast, *Parkia* (Parkieae) is primarily bat-pollinated (Baker & Harris, 1957; Hopkins, 1984), although a few species are pollinated by insects (see discussion in Hopkins, 1984).

High-energy pollination systems such as those involving hawkmoths, birds, and bats are concentrated among the genera of the more advanced tribe Ingeae (Cruden et al., 1976; Arroyo, 1981; Koptur, 1983; Hernández, 1986a; unpublished obs.). In the Ingeae, the transition from low-energy insect pollination to high-energy systems, which demand greater allocation to nectar and pollen, is associated with inflorescence modifications. For instance, connation of the staminal filaments to form a tube and increase in number and length of the filaments made it possible for the flowers to hold larger quantities of nectar necessary to satisfy the energy requirements of larger, homothermic pollinators. Similarly, changes in periodicities of nectar and aroma production, nectar quality, and timing of anthesis have enabled the plants to adjust to the physiological and behavioral characteristics of particular pollinators.

Mimosoideae have a number of additional reproductive traits that make them extremely interesting from an ecological and evolutionary point of view. Guinet (1969, 1981) discussed in detail that the most conspicuous feature of mimosoid pollen is the occurrence of permanent units of dispersal in the form of tetrads, octads, and polyads throughout the subfamily. Such units of pollination presumably provide the plants with a selective advantage in reproduction. As has been demonstrated for *Acacia* species (Kenrick & Knox, 1982; Knox & Kenrick, 1983), a single pollen unit is able to fertilize all the ovules in the ovary. Another widespread feature of the mimosoid inflorescences that is important in the breeding systems of the species is the occurrence of female sterile flowers. Viewed in an evolutionary perspective, these reproductive phenomena have great potential as characters on

which to base phylogenetic interpretations. Published reports concerning the reproductive biology of the species here assigned to *Zapoteca* are virtually nonexistent, and the present chapter is intended to provide an account, based on my own observations, of some of the reproductive features of these plants.

METHODS

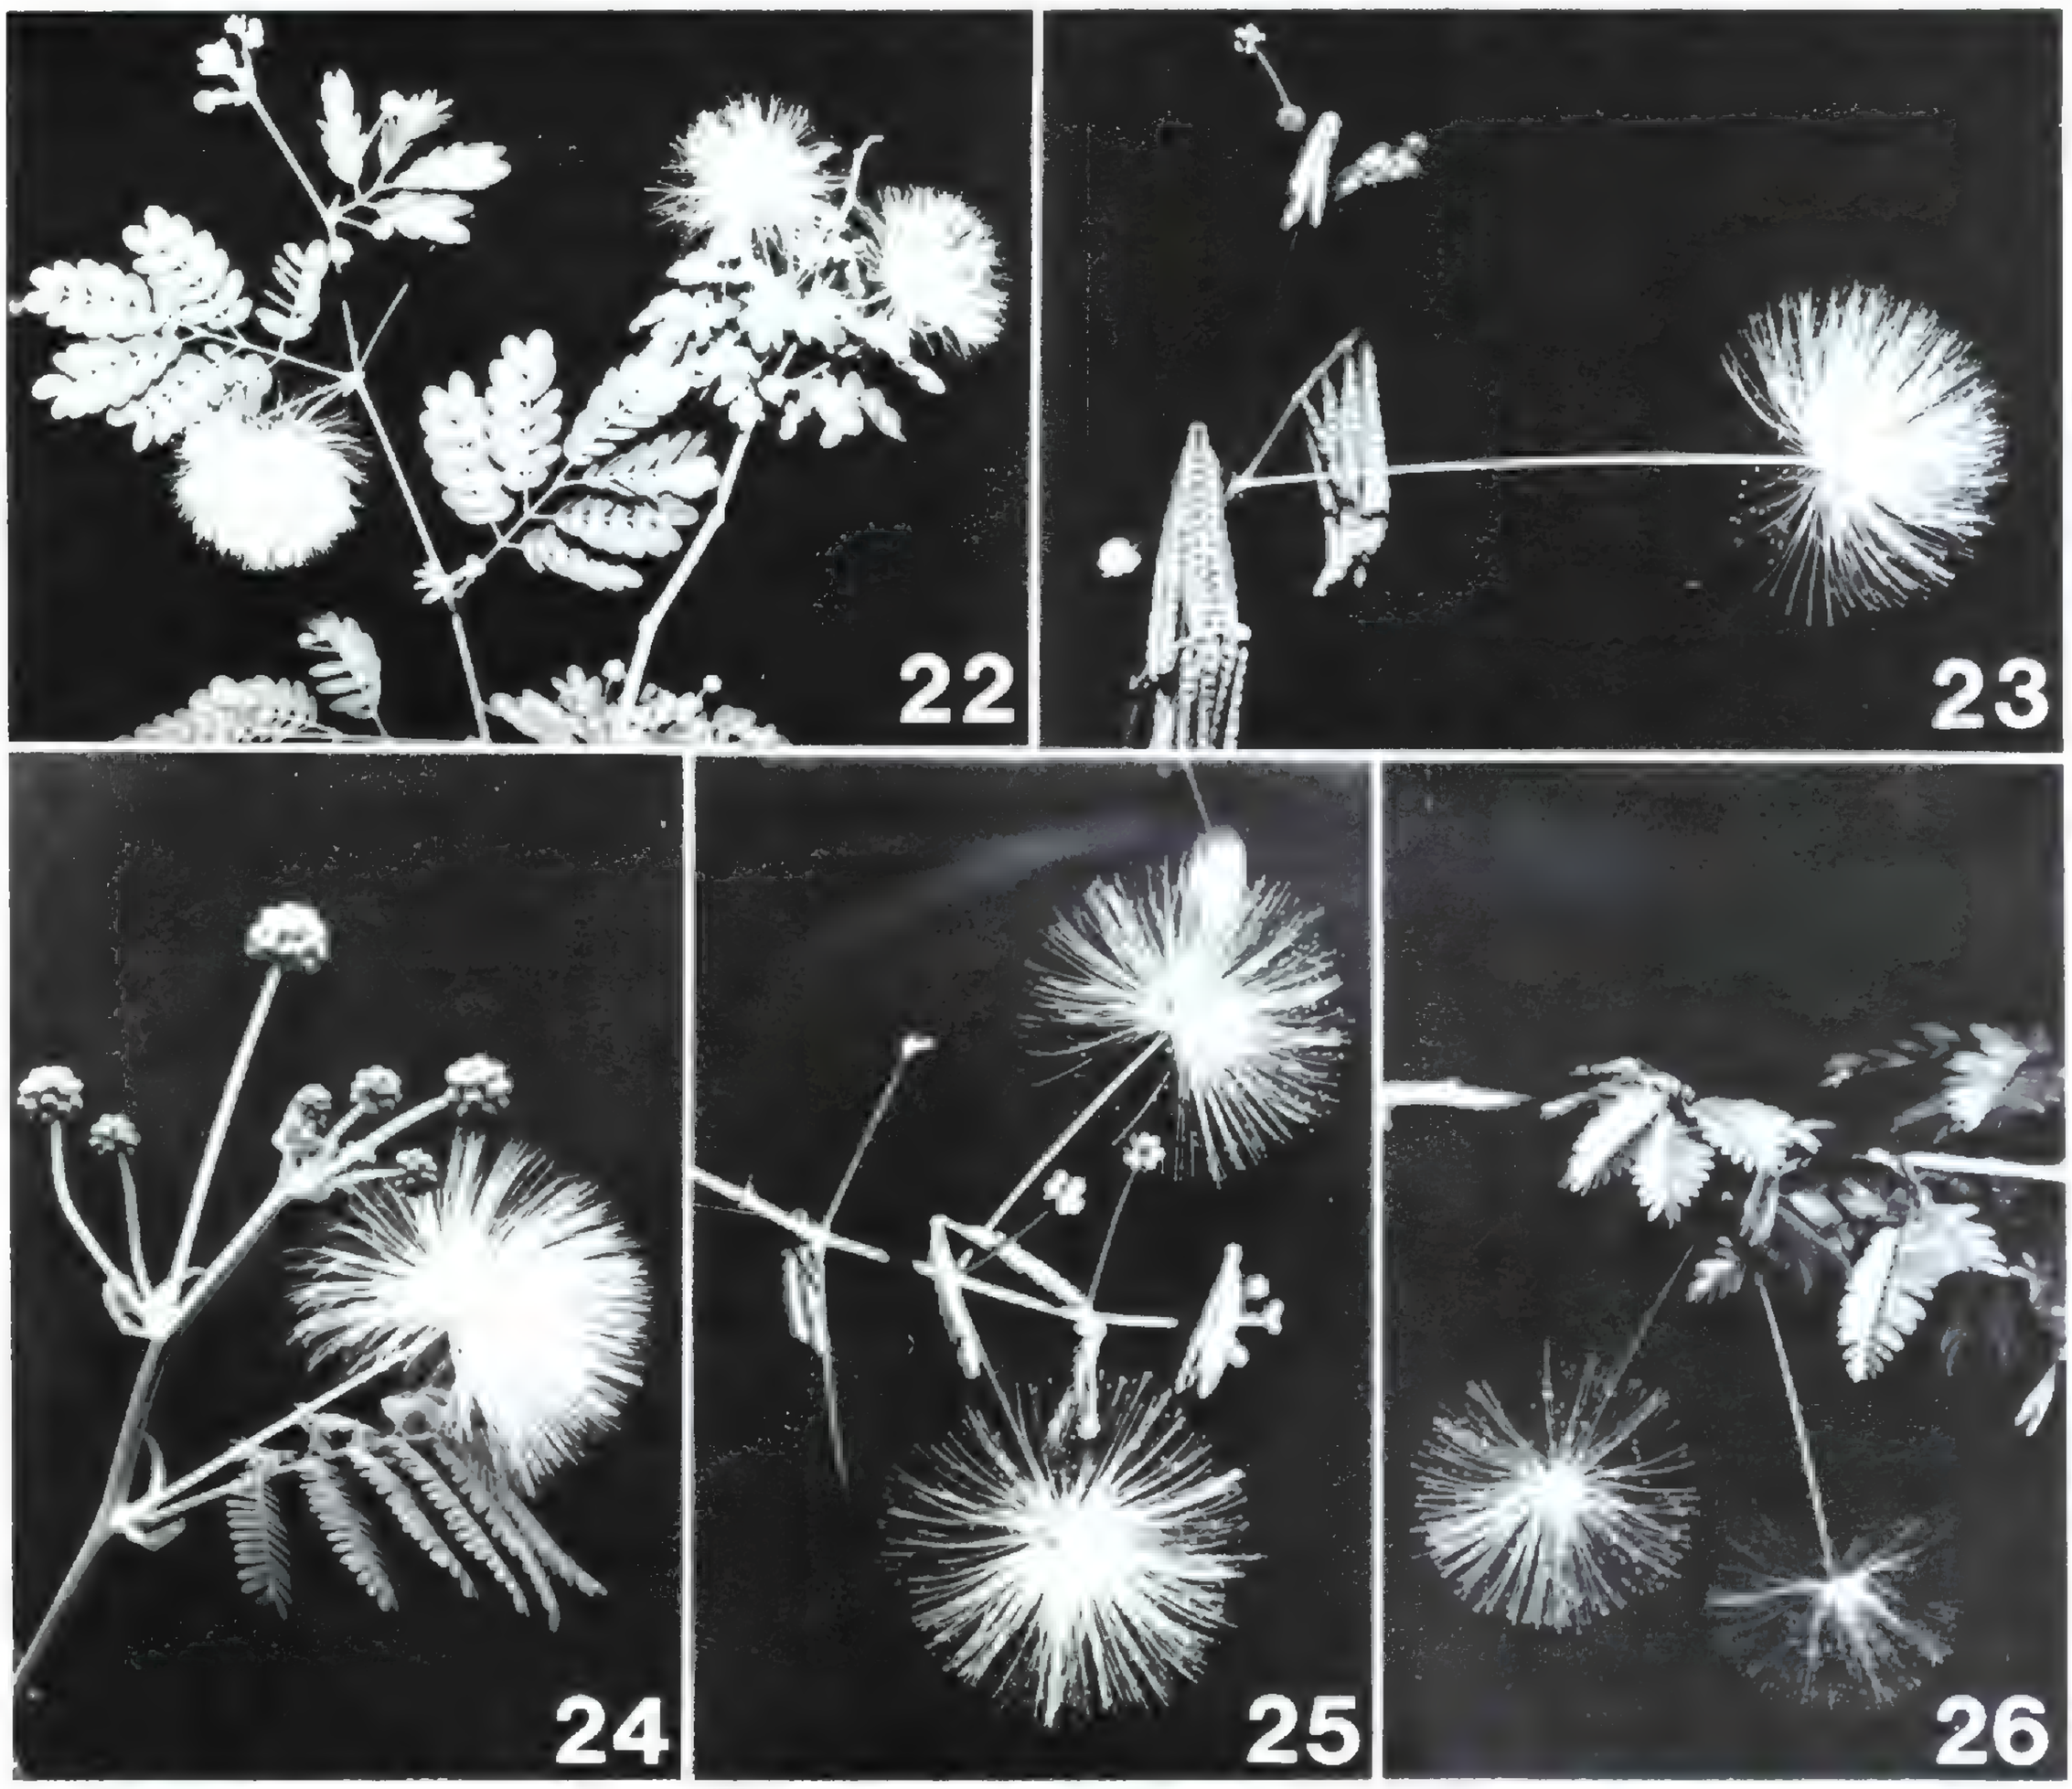
Nectar volumes were measured with calibrated micropipets, and sugar concentrations were determined using a temperature-compensated Erma hand refractometer. In a few cases, when the flowers were very small, a syringe was used to extract the nectar from the staminal tubes. All measurements were made in the greenhouse early in the morning in order to estimate the total amount of nectar produced per flower. Between four and ten individuals per population were examined. It is quite possible that the results in Table 6 might be lower volumes than would be found in the wild, since it has been shown that nectar volumes and sugar concentrations may be significantly lower in plants growing in greenhouse pots compared with wild plants (Cruden & Hermann, 1983). However, they allow species comparisons.

Field observations on flower visitors were carried out continuously during the first three to five hours of anthesis. Since all *Zapoteca* species flower at night, the behavior of flower visitors was observed with the aid of a head lamp. In most cases, visitors were successfully collected with insect nets. Insect voucher specimens are deposited in the Entomological Collection at the Instituto de Biología, UNAM.

The number of ovules per gynoecium was determined by squashing fixed ovaries in a drop of Alexander's stain (Alexander, 1969); the ovaries were examined with a compound light microscope within 15–20 minutes after staining. Sex expression was characterized for each population by dissecting fixed flowers and counting the proportion of hermaphrodite and female-sterile flowers in each inflorescence. Self-compatibility was assessed on plants growing in the greenhouse using the techniques outlined by Bawa (1974). Pollinations were accomplished using a fine brush within four hours of the beginning of anthesis, once the anthers were dehiscent. Anther dehiscence was determined by touching the anthers with a clean microscope slide; a large number of polyads on the slide revealed open thecae. Given the small size of the flowers, the inflorescence was taken as a unit in the pollination treatments. In every population, a determined number of inflorescences were artificially cross- and self-pollinated, and several additional inflorescences were left untreated (open) to test for autogamy. Due to the difficulty involved in emasculating the delicate flowers of *Zapoteca*, the possibility of apomixis was not tested. For the cross-pollinations, mixtures of polyads from several individuals were used whenever possible. For the self-pollinated inflorescences, the pollen donor was taken from the same inflorescence or from other inflorescences in the same individual; therefore, a great number of these flowers were geitonogamously pollinated. Treated inflorescences were marked with hanging labels. As the greenhouse was insect-free, inflorescence manipulation was minimized by avoiding the need to bag inflorescences. Sample size varied from two to nine individuals per population. After each treatment, brushes and hands were sterilized with ethanol. Since pod abortion occurs in *Zapoteca* species at several stages of pod development, the resulting pods were counted only if they matured fully. Seed set was estimated in every population by calculating the average number of fully developed seeds in mature pods.

FLOWERING PHENOLOGY

Although it is difficult to characterize the phenological behavior of a given species throughout its range, I shall attempt to draw some generalizations about the flowering patterns in *Zapoteca*. This discussion is based primarily on species restricted to Mexico and Central America. In wide-ranging species such as *Z. tetragona*, flowering times vary from one region to another. This species, which usually grows in secondary vegetation derived from lowland tropical wet forests, flowers mostly during the dry season; nevertheless, in the Mexican state of Morelos, where a more seasonal climate exists, the populations flower primarily during the rainy season. *Zapoteca portoricensis* subsp. *flavida*, which grows in wet habitats, also flowers during the dry season. By contrast, the species growing in drier habitats (thorn forests, tropical deciduous forests, and tropical semideciduous forests) tend to flower predominantly during the second half of the rainy season (e.g., *Z. formosa*, *Z. lambertiana*, *Z. media*, *Z. alinae*). The species from drier areas have shorter, more synchronized flowering periods than species living in wetter habitats (e.g., *Z. amazonica* and *Z. tetragona*), which continue to produce flowers for longer periods. Finally, *Z. portoricensis* subsp. *portoricensis*, which generally grows in montane mesophyllous forests (terminology following Rzedowski, 1978), also flowers in the wet season.



FIGURES 22–26. Inflorescences of *Zapoteca* species at anthesis; all photographs were taken at night. 22. *Z. formosa* subsp. *formosa* (right) and *Z. formosa* subsp. *rosei* (left) (*H. Hernández 216*, *217*, respectively).—23. *Z. portoricensis* subsp. *portoricensis* (*H. Hernández 948*).—24. *Z. tetragona* (*H. Hernández 956*).—25. *Z. media* (*H. Hernández 951*). 26. *Z. tehuana* (*H. Hernández 950*). All collections at MEXU and MO.

A possible explanation for this differential flowering pattern is that in wet areas excessive rains may have destructive effects on the delicate inflorescences of *Zapoteca* and may reduce the activity of potential pollinators (Janzen, 1967). I observed the devastating effects of rain on inflorescences of several *Zapoteca* species in wet and dry forests. These effects are clearly reduced in areas of less precipitation.

As far as I have observed, species of *Zapoteca* display two distinct flowering strategies. Most species (e.g., *Z. formosa*, *Z. media*, *Z. portoricensis*, *Z. tetragona*) have a very generalized flowering behavior. Here regular numbers of inflorescences open every night over several months. By contrast, *Z. alinae* exhibits a more specialized strategy. Individuals of this species intermittently produce relatively large numbers of inflorescences on scattered nights throughout its flowering period, from July to September. This specialization is similar to the "multiple-bang" strategy described by Gentry (1974) for tropical Bignoniaceae. It differs, however, in that the flowering is not synchronized among the different individuals that make up a given population of *Z. alinae*. One possible adaptive value of this strategy is that these flowering bursts produce conspicuous visual and olfactory stimuli, thus increasing the chances of pollinator attraction.

THE INFLORESCENCE AS THE UNIT OF POLLINATOR ATTRACTION

Species of *Zapoteca* always have their flowers arranged in compact, homomorphic, capitate inflorescences, which act as units of attraction (Figs. 22–26). In each flower, the numerous elongate

TABLE 6. Volume and sugar density of nectar in selected species of *Zapoteca*. All collections in MO. H = author's collections.

Taxon	Collection Data	Volume (μl) $\bar{x}$ (±S.D.)	Sugar density (%) $\bar{x}$ (±S.D.)
Z. alinae	Mexico, Oxaca, *H-949*	< 1	17.27
Z. formosa	Mexico, Jalisco, *H-230*	< 1	13.9
Z. lambertiana	Mexico, Chiapas, *H-891*	< 1

Z. portoricensis	Mexico, Veracruz, *H-948*	1.04(0.8)	18.43(3.4)
Z. tetragona	Mexico, Veracruz, *H-956*	3.05(2.0)	19.83(2.5)
Z. tetragona	Mexico, Veracruz, *H-960*	5.12(2.0)	20.32(3.2)

filaments, which give the inflorescences their attractive powder puff aspect, are fused basally, forming a tube in which nectar accumulates.

Anthesis and the process of flower presentation. Field and greenhouse observations have shown that species of *Zapoteca* display predictable flowering mechanisms. All members of the genus exhibit nocturnal anthesis and a remarkable synchrony in floral behavior during flower presentation. Usually the filaments of all the flowers in a head become erect in a springlike fashion late in the evening (ca. 17:00–18:00 hours), during the last two hours of daylight. Subsequently, when the filaments are completely erect (ca. 18:00 19:00 hours), the anthers dehisce. At about the same time, nectar secretion begins, accompanied by production of a sweet aroma. Each head remains functional for only one night and the filaments wilt within approximately the first two hours of daylight.

Attractants: filament color and aroma. With few exceptions, the color of the staminal filaments is constant in a given species of *Zapoteca* and thus is of taxonomic value. The filaments may be white (e.g., *Z. alinae*, *Z. portoricensis*, *Z. tetragona*), red-purple (*Z. lambertiana*), or a combination of white in the basal half and pink or red-purple in the distal half (e.g., *Z. amazonica*, *Z. caracasana*, *Z. media*). The widespread *Z. formosa* shows some geographical variation in filament color, and the recognition of subspecies within this species is based in part on this feature. This character is nearly always stable at the population level in *Z. formosa*; however, in a population observed in eastern Oaxaca a mixture of plants with white (*H. Hernández & Torres 216*) and white/pink filaments (*H. Hernández & Torres 217*) turned up. Similarly, individual plants of *Z. tehuana* with either white or white/pink filaments were observed in a greenhouse population (*H. Hernández 950*). The flowers of all species of *Zapoteca* produce a delicate, sweet fragrance, which presumably functions as does the color of the stamens in attracting pollinators (Brantjes, 1978).

Rewards: nectar production. The amount of nectar produced by individual flowers varies among the species of *Zapoteca*, perhaps as a function of the size of the nectaries and the physical capacity of the staminal tube. As shown in Table 6, all the species analyzed except *Z. tetragona* produce quantities of nectar below or slightly above one microliter (μl) per flower. In the two populations of *Z. tetragona* (the species with essentially the most massive flowers in the genus), the nectar volumes were substantially higher (Table 6). The nectar of *Zapoteca* species has rather low sugar concentrations, ranging from 13.9 to 20.3%. The nectar volumes and sugar concentrations in the flowers of *Zapoteca* species reported here agree with those reported by Opler (1983) and Baker & Baker (1983) for settling moth-pollinated flowers.

FLOWER VISITORS

Inflorescences of *Zapoteca* species are well adapted for pollination by moths. Field observations conducted in ten different populations representing five species of *Zapoteca* clearly showed that the flowers are consistently visited and pollinated by a variety of settling moths, mostly of families Noctuidae, Pyralidae, and Geometridae (Table 7). The moths were usually observed to visit the inflorescences after some nectar had accumulated in the staminal tube and after floral fragance was detected by observers. Moths usually landed in the upper part of the inflorescence, where the underside of their bodies contacted the anthers and the stigmatic surfaces (Fig. 27). Moths generally moved from one part of the inflorescence to another in search of nectar, and the length of time they remained on an inflorescence was often up to 20 30 minutes. Aside from the species in Table 7, a substantial

number of species of smaller moths were excluded because they were considered to be ineffective pollinators.

Many species of moths were observed to exploit the nectar of *Z. tetragona* (population J) illegitimately. They extracted nectar by standing on the peduncles without touching the anthers and stigmas. However, five species of moths were observed to visit the flowers of this species legitimately; among these, *Palpita flegia* (Fig. 27) and *Diaphania jairusalis* may be considered the primary pollinators on the basis of their abundance (Table 7). The color of the wings of these two species is strikingly similar to that of the white filaments of *Z. tetragona*. In contrast, the nectar robbers, along with the few other occasional pollinators, have wings with a variety of color patterns.

Although inflorescences of *Zapoteca* species display the typical syndrome of characteristics associated with hawkmoth pollination (Faegri & van der Pijl, 1979), hawkmoths were rarely observed as visitors. During the course of my observations, only two hawkmoths were observed, one visiting the flowers of *Z. formosa* (population C) and one on *Z. lambertiana* (population J). A possible explanation for this is that the individual flowers produce rather small amounts of nectar, making the visits energetically unprofitable to hawkmoths. According to Opler (1983) and Haber & Frankie (in press), hawkmoth-pollinated flowers usually produce much greater amounts of nectar (maximum available nectar $\bar{x}$ = 130.5 μl; Opler, 1983) compared with the relatively smaller amounts found in the flowers of *Zapoteca* (Table 6).

Two unidentified species of crab spiders (Araneida: Thomisidae) were observed preying on moths visiting the inflorescences of *Z. formosa* subsp. *rosei* and *Z. portoricensis* subsp. *portoricensis*. These light-colored spiders would be inconspicuous on the inflorescences of *Zapoteca* species, where their cryptic coloration permits them to prey on flower visitors. Given that the spiders occurred in very low numbers, their negative impact on the reproductive potential of the plants is probably unimportant. Such an association between crab spiders and flowers has been reported by other authors (Wickler, 1968; Kevan, 1972; Gertsch, 1979, and others).

FIGURE 27. *Palpita flegia* visiting the flowers of *Zapoteca tetragona* in a population near Catemaco, Veracruz (*H. Hernández 799*, MEXU, MO).

POLLINATION RELATIONSHIPS

All species of *Zapoteca* have very delicate, cup-shaped stigmas, and as indicated elsewhere (Hernández, 1986a), the concave area of receptivity is so narrow that only a single 16-grained polyad can be held (see fig. 11 in Hernández, 1986a). Considering that the likelihood of a pollen unit reaching the stigma is directly proportional to the receptive area of the stigma (Cruden & Miller-Ward, 1981), one might anticipate that the chances of successful pollination in species of *Zapoteca* are rather low. As pointed out earlier, however, the settling moths that were recorded visiting species of *Zapoteca* normally remain on the inflorescences for considerable periods of time. The chances of successful pollination are also affected by the time the body of a particular pollinator makes contact with the stigma; therefore, the relatively long visits by settling moths compared with hawkmoths might be understood as a compensating factor to the intrinsic low chances of a polyad reaching the stigma in *Zapoteca*.

The average number of ovules per ovary in *Zapoteca* species is highly correlated with the number of pollen grains in the polyads. As indicated in Table 8, the number of ovules ranges from 11 to 15 and never exceeds the number of grains in the polyad (16). Therefore, the ratio of grains per polyad to the number of ovules is close to one,

ranging from 1.04 in *Z. formosa* to 1.45 in *Z. alinae*. An almost identical situation has been reported by Kenrick & Knox (1982) and Knox & Kenrick (1983) for species of *Acacia*. In this genus, however, the range of variation in the ratio of number of grains to number of ovules is somewhat broader than in *Zapoteca*, but the species of *Acacia* with 16-grained polyads also have ratios approaching one (Kenrick & Knox, 1982). In *Calliandra* (sensu Hernández, 1986a) ratios also vary around one; however, in several species of the highly advanced ser. *Racemosae*, the number of ovules greatly exceeds the eight grains found in the polyads (Nevling & Elias, 1971; Cruden, 1977; Hernández, 1984, and unpublished results). This reduction in the ratio of number of grains to number of ovules is probably associated with the highly modified fungiform, discoid, or capitate stigmas found in *Calliandra*, which have a greater area of receptivity than the representatives of the other genera mentioned (Hernández, 1986a).

BREEDING SYSTEMS

Sex expression. In species of *Zapoteca*, sex expression and genetic self-incompatibility systems are the primary components of the breeding system that affect pollination and fertilization. Analysis of the inflorescences of several species has shown that morphologically expressed andromonoecy resulting from abortion of the gynoecium is widespread in the genus (Table 9). Functionally male flowers with an aborted gynoecium are irregularly distributed among populations. Generally, individual plants have inflorescences with varying proportions of hermaphroditic and functionally male flowers; however, individuals with inflorescences composed entirely of hermpahroditic flowers are not uncommon.

Z. tetragona	*Neill 5388*	13.4 ± 0.71 (32)	1.2

The ratios of hermaphroditic to female-sterile (functionally male) flowers change during the course of the flowering season in individual populations. Therefore, the figures provided in Table 9, which correspond to a single stage of the flowering cycle in each population for which data are enumerated, do not reflect the actual proportions of the two flower types.

Table 9 indicates a great amount of intra- and interspecific variation in sex expression among the species of *Zapoteca*. The ratios of hermaphroditic to female-sterile flowers varied from 0.4 to 77.5 in the studied populations. Thus far, I have been unable to establish any correlation between the nature of sex expression and factors such as altitude, frequency of pollinator visitation, and incompatibility systems. Nevertheless, a planned, detailed analysis of temporal variation in the ratios of hermaphroditic to female-sterile flowers in natural populations would probably contribute significantly to understanding this reproductive phenomenon.

Incompatibility systems. The results of the incompatibility experiments show that of the five species studied, only *Z. tetragona* is clearly genetically self-incompatible, as indicated by the inability of the flowers to set pod following the self- and open-pollinated treatments in the two populations (Table 10). In contrast, plants of the two populations of *Z. formosa* that were studied proved to be genetically self-compatible, and those from one additional population (*H. Hernández 959*) were partially autogamous, judging from the fact that a relatively high proportion of the untreated inflorescences (20%) set pods (Table 10).

Incompatibility studies on the remaining species (*Z. media*, *Z. alinae*, *Z. portoricensis*) were inconclusive but suggested that these species are genetically self-compatible, at least in part. In both *Z. media* and *Z. alinae*, pod set was significantly higher in untreated (open) inflorescences compared with the self-pollinated inflorescences (Table 10), although this may have been partly the result of mechanical damage to floral parts during the hand pollinations. In *Z. portoricensis*, the difference in pod set between the untreated and the self-pollinated inflorescences was less pronounced; however, the few pods that were derived from the hand self-

TABLE 9. Sex expression in flowers of *Zapoteca* species. Collections in MO. H = author's collections.

pollinated inflorescences developed no mature seeds. In contrast, the pods set in untreated inflorescences produced a relatively low average number of seeds per pod (2.8), which indicates some degree of genetic self-compatibility in *Z. portoricensis*. Presuming that there was no accidental transfer of polyads among the untreated plants, the individuals of all three species tested were at least in part genetically self-compatible.

CONCLUDING REMARKS

Zapoteca species are relatively consistent in several important features of reproductive biology. All the observed species exhibit nocturnal anthesis. The small flowers are organized in compact, capitate inflorescences, and there is remarkable synchrony among the flowers of a given capitulum in all the stages of flower presentation and in the patterns of aroma and nectar production. This suggests that ecologically the spherical capitula act as units of attraction. The particular combination of morphological and behavioral features in the inflorescences of species of *Zapoteca* is well adapted for pollination by settling moths. Moreover, the remarkable morphological correlation between the stigmas and the polyads in *Zapoteca*, along with the specific behavior of its pollinators, reflects a highly organized reproductive system. Reduction in the number of ovules in each ovary increases the reproductive efficiency of these species, giving a single polyad the potential of fertilizing all the ovules in an ovary. In other words, the high correlation between the number of ovules in an ovary and the number of pollen grains in a polyad is a reflection of the high probability of the ovules being fertilized by the pollen grains contained in a single polyad.

According to Arroyo (1981), about half of the genera of Mimosoideae are andromonoecious; this condition occurs especially in taxa with capitate inflorescences. The results presented in Table 9 indicate that andromonoecy is widespread in *Zapoteca*, and the presence of a vestigial gynoecium in functionally male flowers strongly suggests that andromonoecy is derived from hermaphroditism in

this genus. Several models have been developed to explain the selective basis for the evolution of andromonoecy (e.g., Heithaus et al., 1974; Ruiz & Arroyo, 1978; Primack & Lloyd, 1980; Dulberger et al., 1981; Bertin, 1982). The following discussion will be centered on the possible factors playing a selective role in the evolution and maintenance of female sterility in *Zapoteca*.

In species of *Zapoteca*, as in the majority of plant species (Stephenson, 1981), the number of flowers produced by individual plants is significantly larger than the number of pods reaching maturity. In natural populations, the vast majority of the capitula abscise after anthesis. Even in the remaining capitula, only a fraction of the fertile ovaries develop into pods. For instance, in a population of *Z. tetragona* near Catemaco, Veracruz (*H. Hernández 800*), it was estimated that each capitulum produced an average of 2.04 (± 1.3; N = 425) mature pods, comparatively few in relation to the average number of hermaphroditic flowers per head (17.8 ± 2.7; N = 100) in the same population. Thus, most of the flowers produced in *Zapoteca* serve only as attractive elements in the inflorescence and as pollen donors (Stephenson, 1981, and references therein).

Rather than being limited by pollinator activity, the inflorescences of the *Zapoteca* species are probably affected by energetic, and certainly by physical–architectural constraints, which set the upper limit for maximum pod production. In this connection, Stephenson (1981) reviewed the available evidence and suggested that "an upper limit to the number of pods that set is usually determined by resources rather than the number of morphologically female flowers, and . . . natural levels of pollination exceed pod set in many species." In this context, the adaptive nature of female sterility can be understood: given the lower pod set in *Zapoteca* populations, a reduction in the number of functional gynoecia in an inflorescence would not reduce pod set. Vestigial gynoecia must be energetically less expensive to produce than the larger, functional ones. Thus, andromonoecy should be understood as a system that makes more efficient use of reproductive energy without compromising pollinator attraction (Ruiz & Arroyo, 1978; Primack & Lloyd, 1980; Arroyo, 1981; Bertin, 1982) and as a means to increase the pollen ovule/ratios and, consequently, the chances of pollination.

Cytogenetics

According to Goldblatt (1981), the genera of the Ingeae consistently have basic chromosome numbers of $x = 13$, with the exception of the highly specialized *Calliandra*, in which $n = 11$ and $n = 8$ have been reported (see review in Hernández, 1986a). As discussed earlier, differential patterns in chromosome numbers and in morphological characteristics provided the justification for the segregation of *Zapoteca* from *Calliandra* sensu Bentham.

Methods

Somatic chromosome counts were obtained from actively growing root tips taken from germinating seeds or mature plants in the Experimental Greenhouse at the Missouri Botanical Garden. The methods employed were those of Goldblatt & Gentry (1979). Root tips were pretreated in 0.003 M hydroxyquinoline for about seven hours at refrigerator temperatures, then fixed in 3:1 absolute ethanol:glacial acetic acid for one minute. The roots were hydrolyzed in 10% HCl for six minutes, then squashed and heated in formic-lacto-propionic orcein.

Results

Chromosome numbers in *Zapoteca* were reported in Hernández (1986a). Counts for two additional taxa are included here (Table 11). All cytologically investigated species of *Zapoteca* have $n = 13$ (Figs. 28, 29), which is consistent with the basic numbers reported for the remaining genera of Ingeae (Goldblatt, 1981). Chromosome numbers are now known for seven of the 17 species recognized in this monograph, all of which are members of subg. *Zapoteca*. The species of the remaining subgenera remain unknown cytologically.

Systematic Treatment

Taxonomic history of *Zapoteca*

Analysis of several critical characters of the neotropical species of *Calliandra*, a large genus currently undergoing revision (Forero, 1984; Hernández, 1984), showed that *Calliandra* sensu Bentham apparently is polyphyletic. Consequently, the species of Bentham's *Calliandra* ser. *Laetevirentes* were recognized as generically distinct (Hernández, 1986a). For this natural group I proposed the name *Zapoteca*.

Mimosa portoricensis Jacq. (= *Zapoteca portoricensis*) and *M. caracasana* Jacq. (= *Z. caracasana*) were the first species to be published of what is now *Zapoteca*. They were described in 1791 on the basis of material collected by the Austrian bo-

tanical expeditions to the West Indies and Venezuela during the second half of the eighteenth century. These species, as well as a few that have been described in *Acacia*, were treated by Bentham as *Calliandra* ser. *Laetevirentes*. Bentham (1875) recognized 12 species in ser. *Laetevirentes*, five of which he described in previous papers (Bentham, 1840, 1844). Seven of the 12 species included by Bentham in ser. *Laetevirentes* are maintained in the present treatment.

The species in Bentham's ser. *Laetevirentes* were treated by Britton & Rose (1928) as *Anneslia* group *Portoricenses* and group *Formosae*. They recognized 25 species within these groups, of which 11 were published as new. Ten of these 25 species are maintained in the present treatment, including two of the new species. Three additional species, all of them clearly recognizable as *Zapoteca*, were arbitrarily included by Britton & Rose under *Anneslia* group *Molliculae*. Britton & Rose's treatment is characterized by excessively narrow definitions of taxa, and their subdivisions are artificial. Britton & Rose studied only a fraction of the over 4,000 herbarium specimens that were available for the present study. *Calliandra* was conserved over *Anneslia* (Bunting, 1967; Hernández, 1986b) and, as a consequence, a number of names recognized by Britton & Rose required new combinations under *Calliandra* in recent regional floras. Since Britton & Rose's treatment, only five new species of *Zapoteca* have been published.

Zapoteca H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. TYPE: *Zapoteca tetragona* (Willd.) H. Hern.

Ramose, erect, scandent, prostrate or subprostrate, glabrous or hairy, unarmed, shrubs, rarely small trees, rarely with spinescent stipules, the young branches terete or 4-angled. Phyllotaxy dis-

FIGURES 28, 29. Mitotic chromosomes of *Zapoteca*. 28. *Z. tehuana*, 2*n* = 26 (prometaphase) (*H. Hernández 950*).—29. *Z. tetragona*, 2*n* = 26 (metaphase) (*H. Hernández 675*). Collections at MEXU and MO. Scale bars = 5 μm.

tichous. Leaves bipinnate; petiole rarely with nectariferous glands, usually with a conspicuous adaxial channel; leaflets 1 to numerous pairs per pinna, opposite, sessile, usually membranous, rarely chartaceous or coriaceous, usually glaucous beneath, glabrous or hairy. Stipules usually conspicuous, leafy, rarely spinescent, persistent. Inflorescences capitate, pedunculate, densely flowered, axillary or organized in simple or compound pseudopanicles, with the peduncles solitary or fasciculate at distant nodes, homomorphic, heterogamic or homogamic. Flowers bracteate, sessile, actinomorphic, (4–)5(–6)-merous; calyx cup-shaped, dentate or denticulate, glabrous or hairy; corolla campanulate or infundibuliform, membranous, with the petals valvate in bud, usually revolute at anthesis; nectariferous disk present in all flowers; stamens ca. 30 60; filaments long-exserted, ca. 19–43 mm long, white, pink, red-purple, or a combination of two colors, the staminal tube included; anthers dithecal, dorsifixed, eglandular, each anther containing 8 polyads; polyads 16-grained, discoid, heteromorphic, usually with eccentric lens-shaped thickenings on the central cells; ovary 1, sessile or shortly stipitate, with ca. 10–15 ovules; style filiform, ca. 15–56 mm long in fertile pistils; stigma cup-shaped. Pods usually pendent, dry, membranous to coriaceous, linear, straight, rarely slightly curved, planocompressed, with the margins thickened, usually with constrictions in interseminal areas, the valves dehiscing elastically from apex to base. Seeds in 1 series, hard, ovoid to rhomboid, rarely ellipsoid, nonarillate, nonalate, usually with irregular or regular 90% pleurogram. Seedlings phaneroepigeal; cotyledons ephemeral, foliaceous, sessile, elliptic to elliptic-ovate; first and second eophylls opposite, the third and fourth alternate; leaflets thin, membranous. $x = 13$.

Distribution. Usually abundant in open sites derived from tropical deciduous forest, or in arid or semiarid, scrubby vegetation and wet evergreen forests, from southwestern United States and northern Mexico, from about latitude 32°30′N, southward through most of Mexico, Central America, West Indies, and part of South America, to northern Argentina at about latitude 27°30′S. Collections come from altitudes of 0 2,850 m.

Zapoteca consists of four subgenera, 17 species, and 11 subspecies. The following systematic treatment includes all the known taxa in the genus. The sequence of the taxa reflects approximate relationships.

Key to the Subgenera and Species of *Zapoteca*

1a. Pinnae 1-, rarely 2-jugate; leaflets usually larger, (1.5–) 2.2–22 cm long, chartaceous to coriaceous, 1 7 pairs per pinna, usually glabrous or ciliate; leaflet venation patterns strongly conspicuous on both surfaces.
  2a. Leaves with cup-shaped glands at the insertions of the pinnae and sometimes between the distal pairs of leaflets; leaflets grayish, olive-green or brown; polyads without lens-shaped thickenings; pods thickly membranous; Hispaniola ..... I. Subgenus *Nervosa* (1. *Z. nervosa*)
  2b. Leaves eglandular; leaflets usually green or olive-green; polyads with lens-shaped thickenings; pods coriaceous; Colombia, Ecuador, and Peru.
    3a. Stipules spinescent; leaflets 3–7 pairs per pinna, ovate-lanceolate, 1.5–6.3 cm long; capitula axillary; Ecuador ..... III. Subgenus *Aculeata* (15. *Z. aculeata*)
    3b. Stipules leafy; leaflets 1 1½ pairs per pinna, falcately lanceolate or falcately ovate-lanceolate, 7 22 cm long; capitula in simple or compound, elongate pseudopanicles; Colombia and Peru ..... IV. Subgenus *Amazonica*
      4a. Leaflets 1½ pairs per pinna, ciliate; stipules to 2 mm long; pseudopanicles simple; filaments white; erect shrubs; Colombia ..... 16. *Z. microcephala*
      4b. Leaflets 1 pair per pinna, glabrous or glabrate; stipules to 22 mm long; pseudopanicles compound; filaments white in the basal half and red-purple distally; scandent shrubs; Amazonian Peru ..... 17. *Z. amazonica*

1b. Pinnae 1 8-jugate; leaflets usually smaller, 0.4 4(5.9) cm long, membranous, rarely thinly chartaceous, 3 67 pairs per pinna, glabrous to densely pubescent; leaflet venation mostly inconspicuous (except *Z. tehuana*); *Z. filipes* and *Z. scutellifera* with somewhat conspicuous veins abaxially ..... II. Subgenus *Zapoteca*
  5a. Leaflets oblong-obovate to very widely obovate (except *Z. formosa* subsp. *gracilis* and occasionally subsp. *rosei* with elliptic to elliptic-oblong leaflets), usually 3–17 pairs per pinna.
    6a. Leaves without glands; stipules lanceolate to ovate-lanceolate, or linear-triangular, to 13 mm long; filaments white, red-purple, white in the basal half and pink distally, or white basally and red-purple distally; essentially erect shrubs; southern United States and northern Mexico to northern Argentina and West Indies ..... 12. *Z. formosa*
    6b. Leaves with scutelliform glands at the petioles, at the insertions of the pinnae, and sometimes between the distal pairs of leaflets; stipules linear-triangular, to 4 mm long; filaments white basally and pink distally; scandent shrubs; Brazil and Bolivia ..... 13. *Z. scutellifera*
  5b. Leaflets narrowly oblong to elliptic or lanceolate, oblong-ovate or oblong-lanceolate (except *Z. costaricensis* with the distal leaflets oblong-obovate), usually 5–67 pairs per pinna.

7a. Leaflets 2–2.7 cm long; stipules ovate to widely ovate, rounded to cordate at the base; Costa Rica ..... 11. *Z. costaricensis*

7b. Leaflets 0.4–2 cm long; stipules triangular to shallowly triangular, triangular-lanceolate, rarely ovate; Mexico to northern Argentina.

8a. Branchlets conspicuously 4-angled, at least in the younger parts.

9a. Filaments white; stipules triangular-linear to triangular-lanceolate, adpressed, without basal auricles, to 2.5 cm long; seeds with regular pleurograms; Mexico to Ecuador ..... 9. *Z. tetragona*

9b. Filaments white basally and red-purple distally; stipules triangular, descending or depressed, with 2 basal auricles, to 0.6 cm long; seeds with irregular pleurograms; Ecuador, Peru, and Bolivia ..... 10. *Z. andina*

8b. Branchlets terete or angled, but never as above (except some populations of *Z. portoricensis* subsp. *portoricensis*).

10a. Leaves with conspicuous, cylindrical glands on the petiole, at the points of insertion of the pinnae, and usually between the leaflets; Brazil ..... 5. *Z. filipes*

10b. Leaves without glands (except *Z. lambertiana* very rarely with minute glands between the proximal pairs of pinnae); Mexico to Brazil and Peru.

11a. Leaflets with the 1°, 2°, and 3° veins conspicuous showing the brochidodromous venation pattern, mostly thinly chartaceous; stipules to 2 mm long; southeastern Oaxaca ..... 14. *Z. tehuana*

11b. Leaflets with the venation patterns mostly inconspicuous, essentially membranous; stipules usually larger than above, to 14(–17) mm long; Mexico to Brazil and Peru.

12a. Pinnae predominantly 1–2(–3)-jugate.

13a. Filaments white basally and red-purple distally; leaves glabrous, pubescent or pilose; stems usually well branched near the base; southern Texas and northern Mexico to Puebla and Oaxaca ..... 2. *Z. media*

13b. Filaments white; leaves glabrous or nearly so; stems usually branched far above the base; Oaxaca ..... 3. *Z. alinae*

12b. Pinnae predominantly 3–7-jugate, rarely 1–2-jugate.

14a. Pods membranous, with the surface usually undulate, glabrous; filaments red-purple; northeastern to southeastern Mexico ..... 4. *Z. lambertiana*

14b. Pods usually more rigid than above (thick membranous), with the surface relatively flat, glabrous, puberulent, densely villous, canescent or pubescent; filaments white, or white basally and red-purple distally; Mexico to Peru.

15a. Filaments white basally and red-purple distally; leaflets 0.4–1.1 × 0.1–0.3 cm; capitula commonly arranged in pseudopanicles, sometimes axillary; subprostrate or prostrate shrubs ..... 8. *Z. caracasana*

15b. Filaments white; leaflets 0.4–2 × 0.1–0.6 cm; capitula commonly axillary, sometimes arranged in pseudopanicles; erect or scandent shrubs.

16a. Pods glabrous or occasionally puberulent; Mexico to South America, and West Indies ..... 6. *Z. portoricensis*

16b. Pods densely villous with long tawny hairs; Costa Rica and Panama ..... 7. *Z. mollis*

I. Zapoteca subg. **Nervosa** H. Hern., subg. nov. TYPE: *Zapoteca nervosa* (Urban) H. Hern.

Caules dense lignosi cortice fissurato. Foliorum pinnae unijugae, nectaria glabra vel sub-glabra; foliola 3–4-juga in pinna utraque, mediocria coriacea, ordinatione venarum manifeste conspicua; stipulae foliosae. Capitula axillaria. Pollinia sine tumoribus lenticularibus. Legumina crasso-membranacea glabra.

Stems densely wooded; the bark fissured. Pinnae 1-jugate, with nectaries, glabrous or nearly so; leaflets 3–4 pairs per pinna, moderately large, coriaceous, with a very conspicuous venation pattern; stipules leafy. Capitula axillary. Polyads without lens-shaped thickenings. Pods thickly membranous, glabrous.

This subgenus comprises a single species, *Z. nervosa*, which has a combination of characters unlike that of any other known species of the genus.

1. Zapoteca nervosa (Urban) H. Hern., comb. nov. *Pithecellobium nervosum* Urban, Symb. Ant. 2: 257. 1900. *Calliandra nervosa* (Urban) Urban & E. Ekman, Ark. Bot. 22A(8): 27. 1928. *Jupunba* (?) *nervosa* (Urban) Britton & Rose, N. Amer. Fl. 23: 27. 1928. TYPE:

Detail of leaflet venation at leaflet apex. —D. Petiolar gland. —E. Flower. (From *Ekman 8959* (US) and *Ekman 8914* (MO); stem and flowers from *Mejia et al. 35509* (MO).)

Haiti: ad Corail, 1,200 m, Dec. 1894, *Picarda 1362* (lectotype, here designated, NY (fragment)). Aside from the fragment at NY, which consists of several leaflets clearly identifiable as this species, there appear to be no additional extant duplicates of Picarda's collection in any of the herbaria where his collections are presumably deposited (B, BR, L, and S). Figure 30.

Shrubs to 3 m high, with slender stems ca. 2 cm diam., the bark fissured; branchlets terete, grayish-brown, smooth, glabrous. Pinnae consistently 1-jugate; petioles terete, with a conspicuous

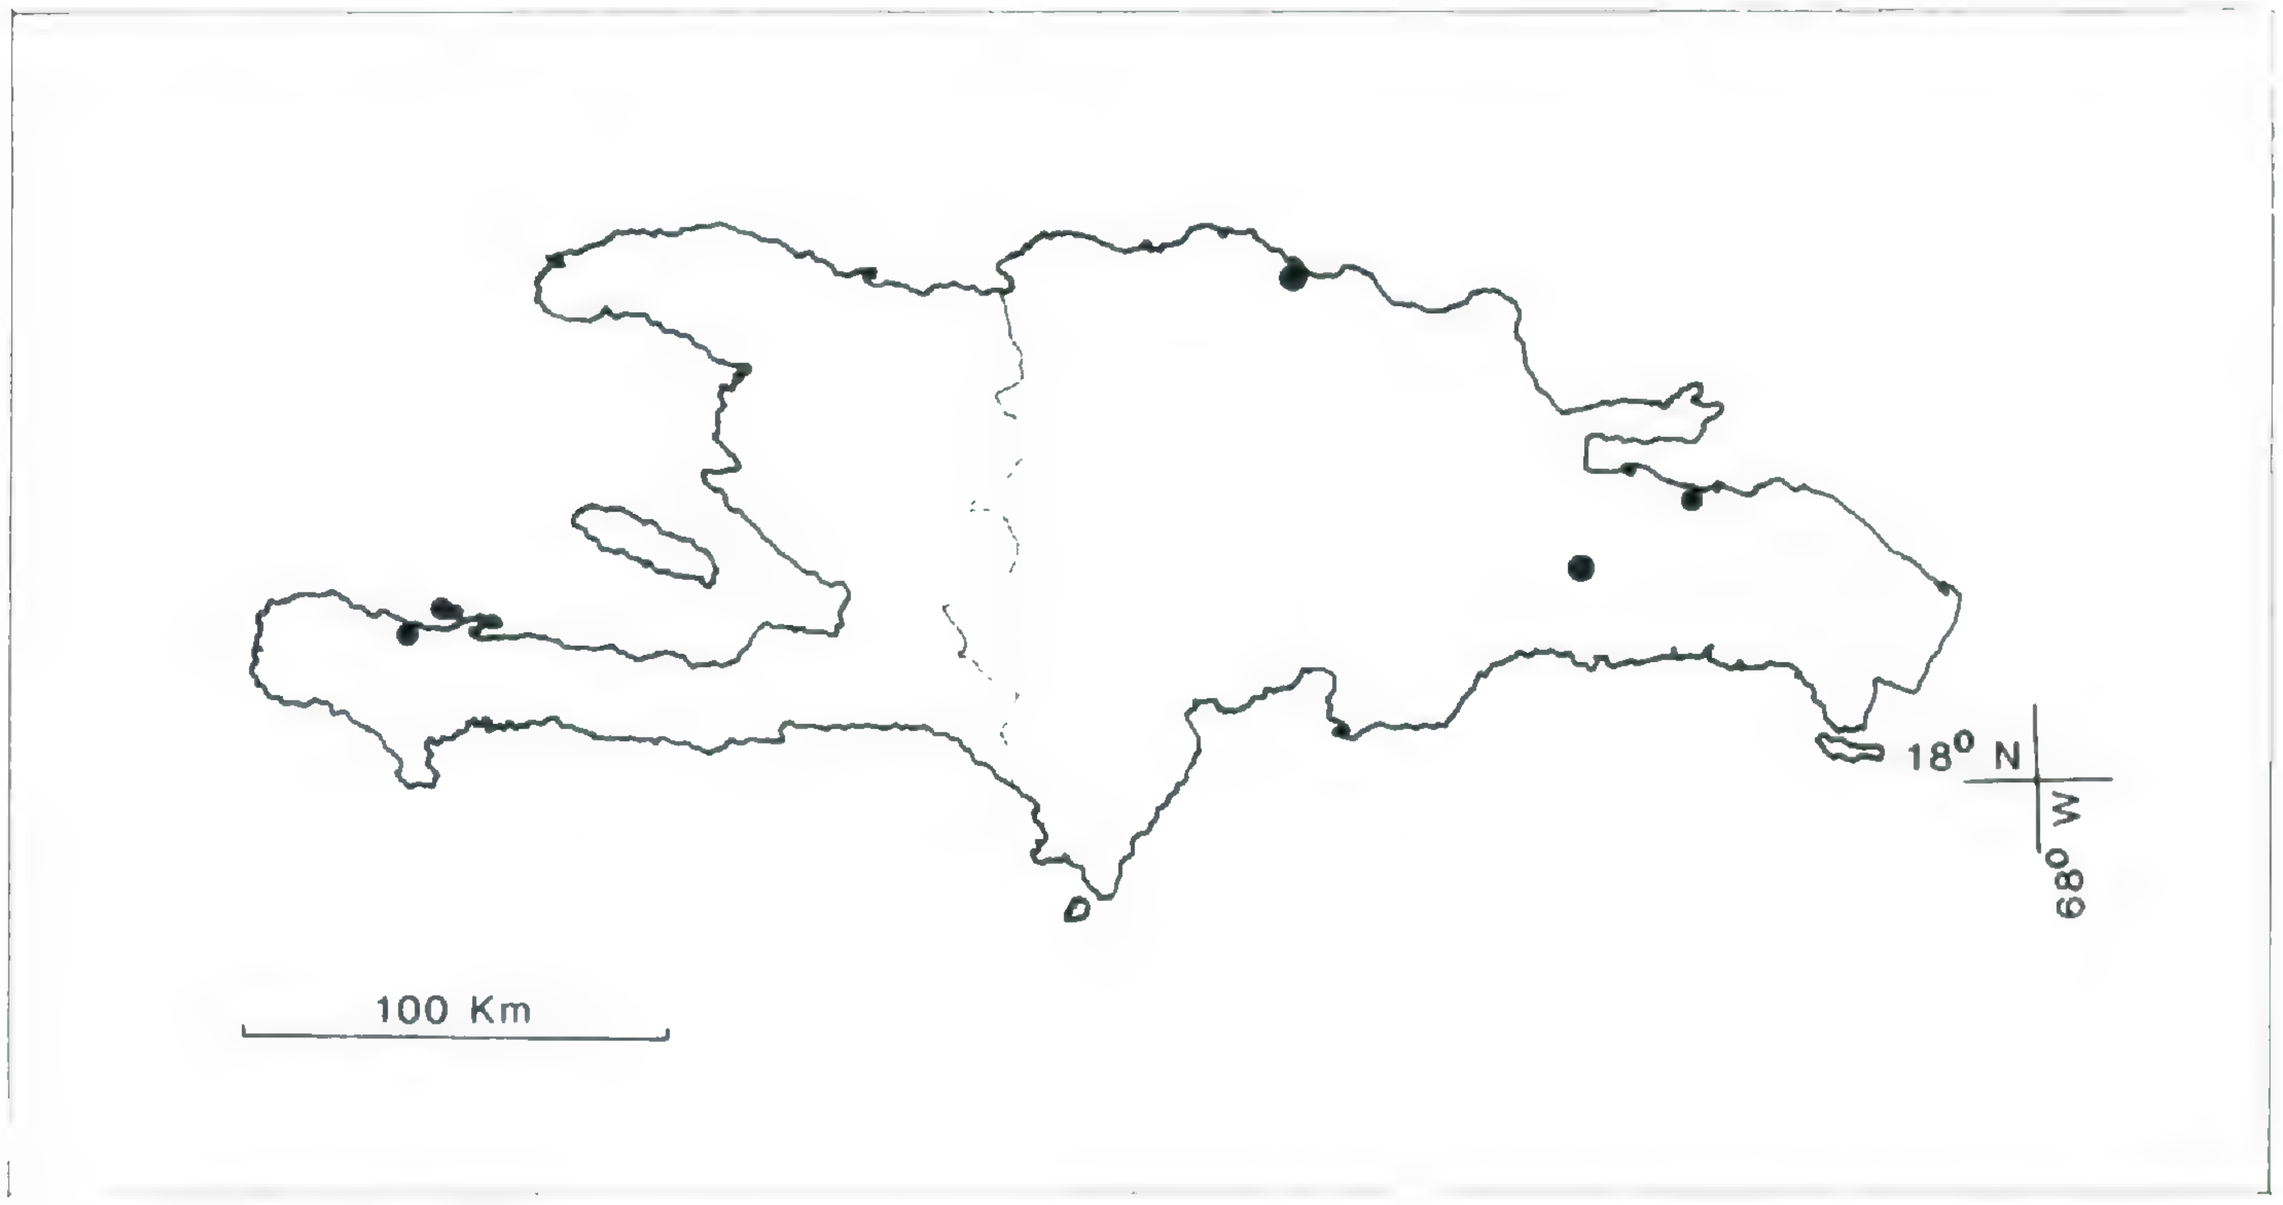

FIGURE 31. Distribution of *Zapoteca nervosa*, Hispaniola.

channel in the adaxial surface, 5–13 mm long, glabrous; rachillae 2.2–7.2 cm long, glabrous, sometimes sparsely villous in the extremes between the leaflets; extrafloral nectaries located at the insertion of the pinnae and occasionally between the distal pairs of leaflets, elevated, cup-shaped, ca. 1 mm diam. or less; leaflets 3–4 pairs per pinna, with the proximal anterior one reduced in size, ovate to lanceolate, sometimes rhombic, the base oblique, the apex obtuse to rounded, sometimes acute, rarely truncate, usually mucronulate, the distal leaflets 2.7–6.8 × 0.9–3.8 cm, the proximal ones smaller, all coriaceous, usually grayish adaxially and olive-green to brown abaxially, glabrous, occasionally floccose abaxially at the base, ciliate when developing; primary, secondary, and higher-order veins very conspicuous on both surfaces; stipules reduced to small scales, deltate, 1 mm long or less, glabrous, rarely villous. Capitula always axillary; peduncles solitary or fasciculate, filiform, (1.6–)3.7–5.5 cm long at anthesis, glabrous, occasionally sparsely pubescent. Calyx denticulate to subtruncate, 1 mm long, glabrous or sparsely pilose, the teeth very shallowly triangular, ciliate; corolla infundibuliform, 4–5 mm long, glabrous, the lobes ovate-lanceolate; filaments purple, the staminal tube ca. 2 mm long; ovary ca. 1.5 mm long, glabrous, the stipe ca. 1 mm long. Pods ca. 8.5–13.5 cm long, rounded at apex, rostellate, thickly membranous, glabrous.

Distribution (Fig. 31). Endemic to Hispaniola, where it has been collected at several scattered localities, mainly on karst limestone, including Ile Grande Cayemite, Haiti; 0–250 m.

Common name. Pti-gaiac (Haiti).

Additional specimens examined. HISPANIOLA ISLAND. HAITI: Grande Cayemite, Anse à Macon, *Ekman 8914* (MO); Grande Cayemite, Anse du Nord, *Ekman 8959* (F, GH, LL, NY, US); Grande Cayemite, *Everman 284* (A, F, GH, MO, NY, US). DOMINICAN REPUBLIC: Civ. Santo Domingo, Cordillera Central, Prov. de Samaná, Los Haitises, Boca del Infierno, *Ekman 15423* (A, GH, US); Los Haitises, near the mouth of Barracote River, S of Samaná Bay, *Liogier 14510* (NY, US); Pilancón, Bayaguana, *Liogier & Liogier 18868* (F, NY); El Choco, Cabarete, Puerto Plata, *Liogier & Liogier 26501* (MO, NY); Prov. Seibo, Parque Nacional Los Haitises, *Mejía et al. 35509* (MO).

This species, the only member of subg. *Nervosa*, is highly isolated morphologically and geographically from the rest of the genus. Its general features and the manner of dehiscence of the pods are identical to those of subg. *Zapoteca*. These characters, as well as the overall characteristics of its inflorescences and flowers, justify its inclusion within *Zapoteca*. It is readily recognized by having fissured bark, extrafloral nectaries, conspicuous eucamptodromous/brochidodromous leaflet venation patterns, large, coriaceous, grayish leaflets, and denticulate to subtruncate calyces, all of which are unique in the genus except the extrafloral nectaries. The stems of *Z. nervosa*, which are characterized by having dense hardwood, differ from those of subg. *Zapoteca*, in which the wood usually is comparatively softer and lighter. Of particular

interest, however, is the absence of the prominent lens-shaped structures in the central cells of the 16-celled polyads (Guinet, pers. comm.), which, as pointed out above, are important diagnostically in the genus. This plesiomorphic character state in *Z. nervosa*, in association with its distinctive morphology, suggests that this species has been separated from the main *Zapoteca* stock since early in the evolution of the genus.

Caules plerumque molliter lignosi, cortice fere laevi. Pinnae (1)2 8-jugae, petiolo plerumque sine nectariis, glabris vel dense pubescentibus, foliolis (2)3–67-jugis in utraque pinna, saepe parvis interdum majusculis, membranaceis raro tenui-chartaceis, ordinatione venarum inconspicua; stipulae foliosae. Capitula axillaria vel in pseudopaniculis simplicibus vel compositis disposita. Pollinia tumoribus lenticularibus praedita. Legumina crasso-membranacea, glabra vel dense pubescentia. Semina pleurogramate praedita.

Stems usually with soft wood; bark essentially smooth. Leaves glabrous to densely hairy, the pinnae (1–)2–8-jugate, the leaf-stalk usually without nectaries, leaflets (2–)3–67 pairs per pinna, usually small, occasionally moderately large, membranous, rarely thinly chartaceous; venation usually inconspicuous; stipules leafy. Capitula axillary or organized in simple or compound pseudopanicles. Polyads with lens-shaped thickenings. Pods thick-membranous, glabrous to densely pubescent. Seeds with pleurogram.

This subgenus is the most diversified evolutionary line within *Zapoteca*, comprising 13 species and 11 subspecies. It ranges from the southern United States and northern Mexico to northern Argentina.

2. Zapoteca media (M. Martens & Galeotti) H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. *Acacia media* M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 10: 316. 1843. *Anneslia media* (M. Martens & Galeotti) Britton & Rose, N. Amer. Fl. 23: 66. 1928. *Calliandra media* (M. Martens & Galeotti) Standley, Publ. Field Columbian Mus., Bot. Ser. 4: 309. 1929. TYPE: Mexico. Hidalgo: Hacienda de Guadalupe près Mextitlán, 5,000 ft., June–Oct. 1840, *Galeotti 3362* pro parte (lectotype, BR; Hernández, Ann. Missouri Bot. Gard. 73: 757. 1986). There are four specimens labeled *Galeotti 3362*, but they are not duplicates of the specimen at BR and consequently are not treated as isolectotypes. The specimen at K is from "ravines de Regla," whereas the ones at G and P are from "ravines de Real del Monte"; a fragment at F lacks locality information. As McVaugh (1978) pointed out, evidence indicates that Galeotti's Mexican collections were sorted systematically and then arbitrarily numbered after they arrived in Europe. In this way, three collections made on different dates were brought together under number *3362* after they were interpreted to represent the same species.

Calliandra angelica Benth., London J. Bot. 3: 100. 1844; Benth., Trans. Linn. Soc. London 30: 544. 1875. *Feuilleea angelica* (Benth.) Kuntze, Revis. Gen. Pl. 187. 1891. TYPE: Mexico. Hidalgo: ravines de Regla, *Galeotti 3362* pro parte [lectotype here designated, K. The sheet at K, where Bentham worked, is the only sheet I have located of *Galeotti 3362* with the locality information specified by Bentham. As noted above, other sheets with this number (at BR, G, and P) have different locality data].
Calliandra coulteri S. Watson, Proc. Amer. Acad. Arts 17: 352. 1882. *Anneslia coulteri* (S. Watson) Britton & Rose, N. Amer. Fl. 23: 66. 1928. TYPE: Mexico. Coahuila: Soledad, 25 mi. southwest of Monclova, Sep. 1880, *Palmer 2129* [lectotype here designated, GH; isolectotypes K, US (fragment)].
Calliandra oaxacana Rose, Contr. U.S. Natl. Herb. 5: 193. 1899. *Anneslia oaxacana* (Rose) Britton & Rose, N. Amer. Fl. 23: 66. 1928. TYPE: Mexico. Oaxaca: granitic ledges, Tomellín Canyon, 4,000 ft., 10 July 1897, *Pringle 6734* (lectotype here designated, US no. 316706; isolectotypes, A, BM, F, GH, K, LE, MEXU, MO, NY, S, UC, US).

Shrubs 0.2–1.5(–3) m tall, the stems slender, usually branching at the base; branchlets terete, costate under magnification, glabrous to densely pubescent or pilose. Pinnae 1–2(–3)-jugate; petioles eglandular, terete, with a conspicuous channel in the adaxial surface, 0.7 4 cm long, glabrous to sparsely pubescent; rachis of 2-jugate pinnae (1) 2–12 mm long; rachilla 1 4.5(–7) cm long; leaflets

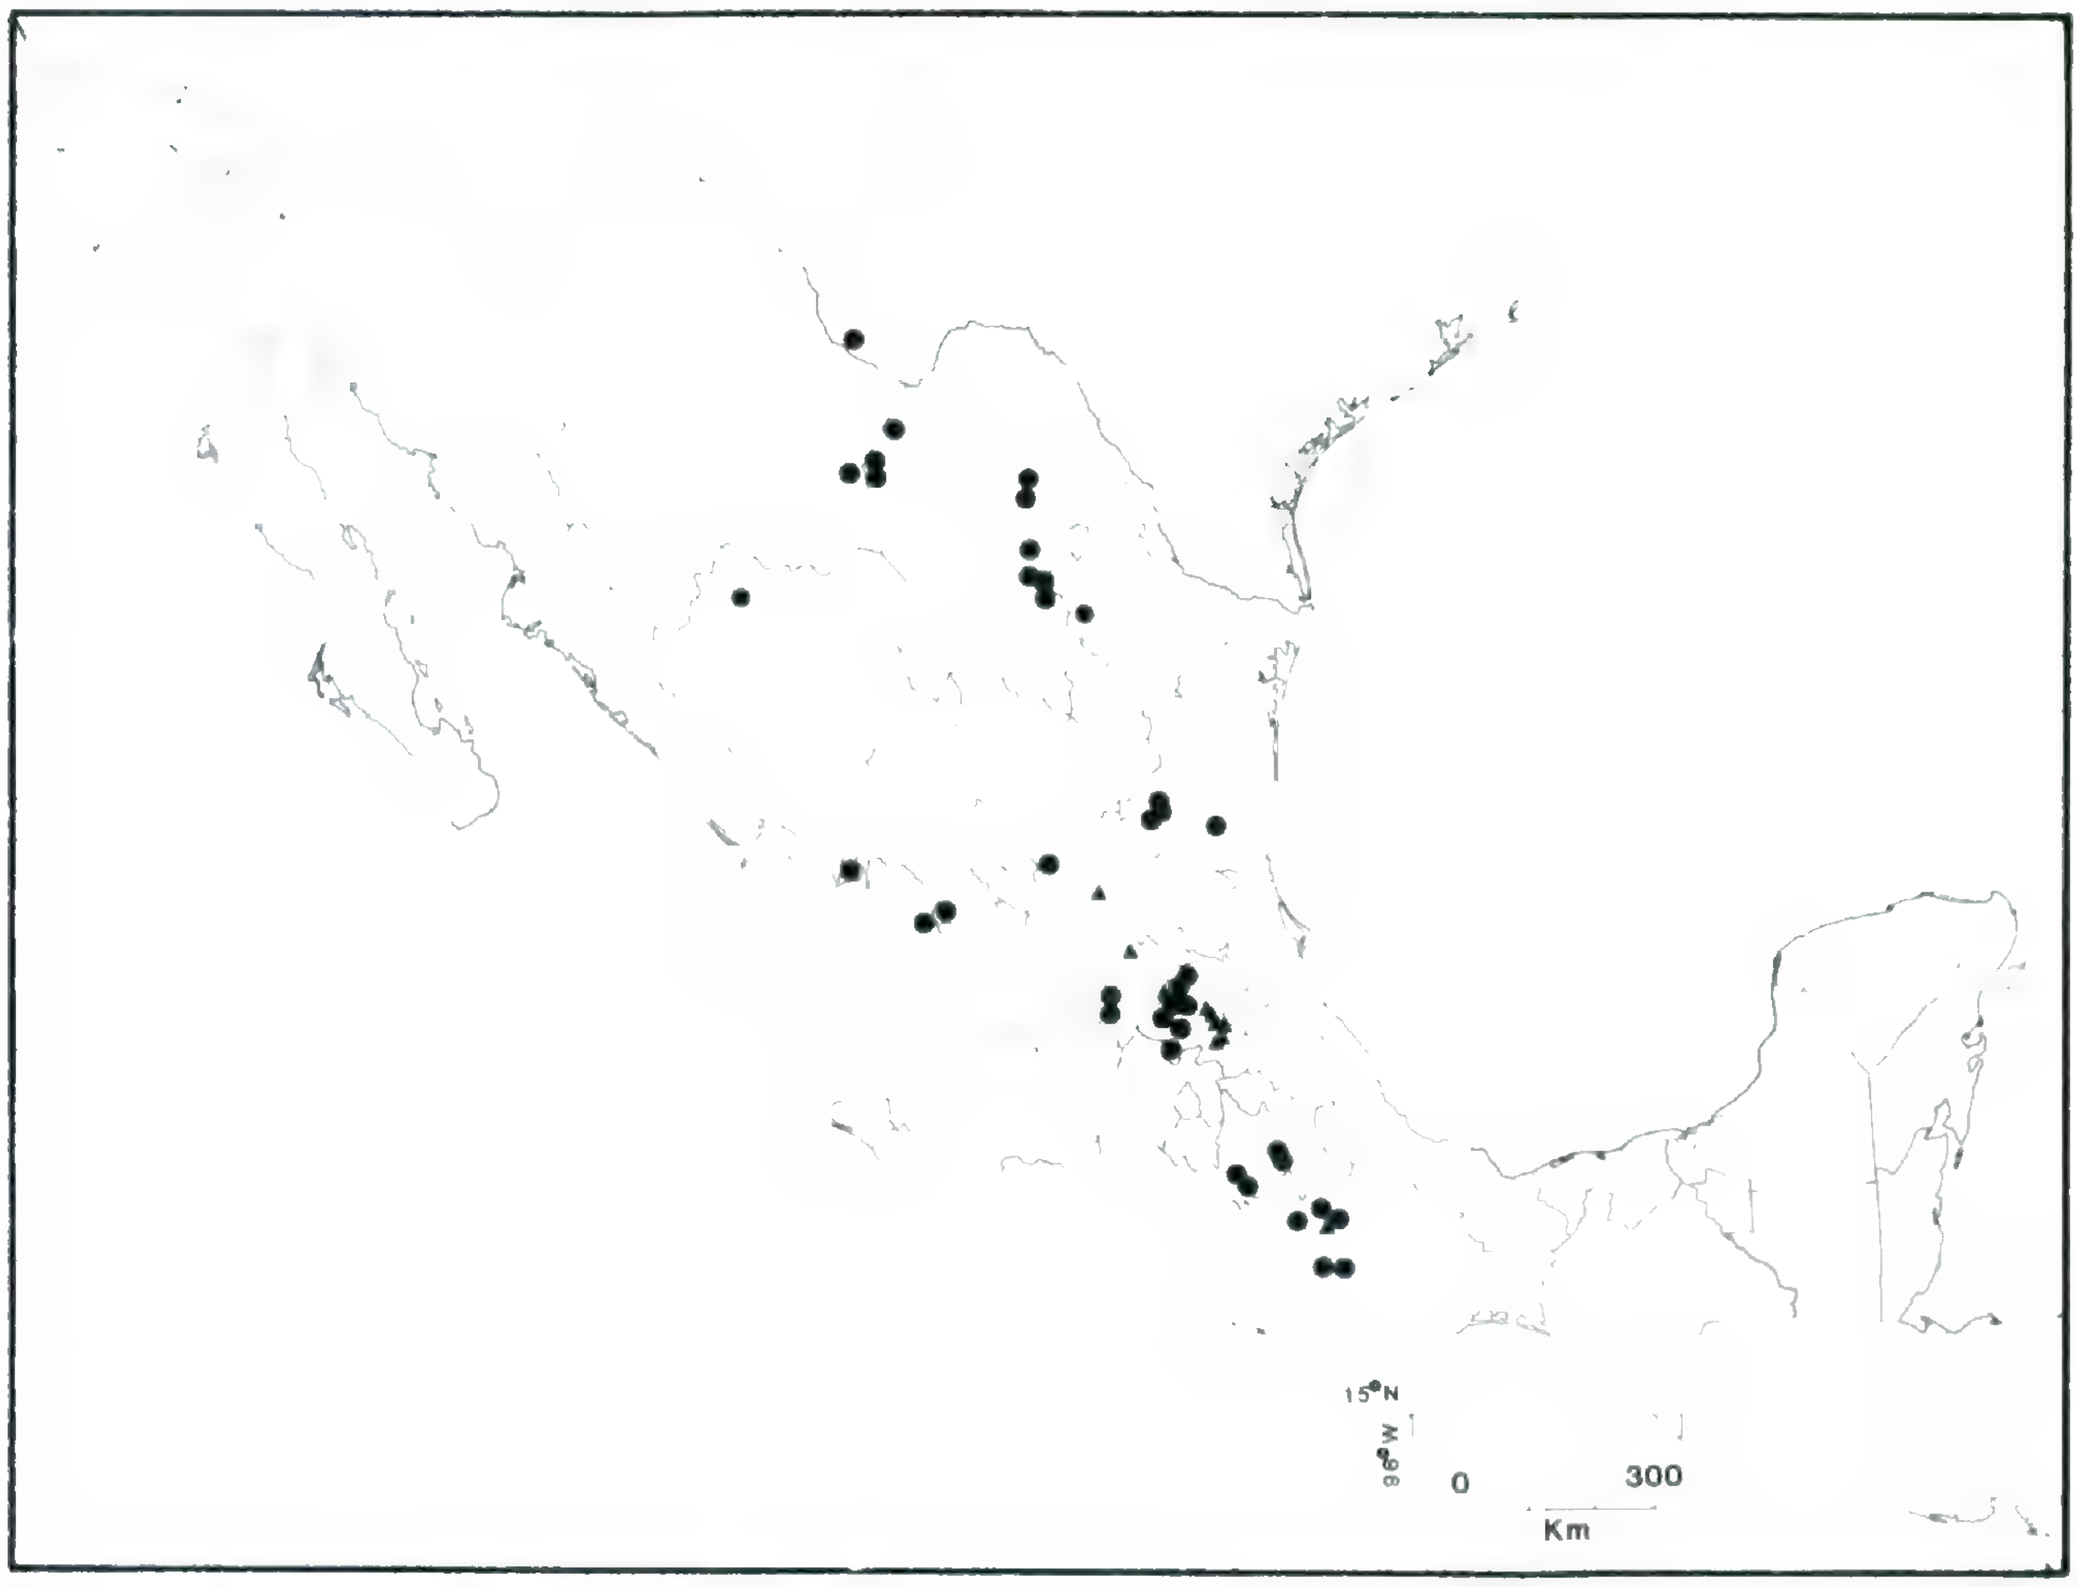

FIGURE 32. Distribution of *Zapoteca media*. Populations with essentially glabrous leaflets = dots; populations with pilose or pubescent leaflets = triangles.

(5–)7–17(–22) pairs per pinna, oblong to elliptic, oblique at the base, except the proximal pairs cuneate at base, acute to rounded at the apex, sometimes rostellate, 4–13 × 1 5.5 mm, membranous, glabrous to pubescent or pilose on both surfaces; leaflet venation usually inconspicuous; stipules leafy, lanceolate to ovate-lanceolate, rarely widely deltate, striate, (1–)2–7 mm long, glabrous to pubescent or pilose. Capitula axillary, rarely in short, terminal pseudopanicles; peduncles solitary or, more commonly, fasciculate at distant nodes, (1–)1.6–7(–10.5) cm long at anthesis, glabrous, sometimes pilose. Calyx ca. 1.5 2 mm long, glabrous or finely ciliate, rarely sparsely pilose, the teeth narrowly oblong, acute at apex; corolla campanulate, ca. 3–3.5 mm long, glabrous, the lobes narrowly elliptic, acute at apex; filaments ca. 20 mm long, white in the basal half, red-purple in the distal half, staminal tube ca. 1–1.5 mm long; ovaries ca. 1 mm long when fertile, occasionally 2 per flower, glabrous, shortly stipitate. Pods to 10 × 0.6 cm when mature, apex rounded to acute or truncate, rostellate, thickly membranous, glabrous, reticulate-veined. Seeds widely rhomboid to widely ovoid, flattened, ca. 4 × 3 mm; pleurogram irregular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 32). This species occurs primarily on dry rocky calcareous slopes and along the margins of seasonal streams in thorn and tropical dry forests, and in arid scrublands. It ranges from the Chinati Mountains (Presidio County) of Texas south over the Mexican Plateau and the arid slopes of the Sierra Madre Oriental and, to a lesser extent, the Sierra Madre Occidental, where it has been collected at scattered localities. Its southern limit is in the districts of Teposcolula, Nochixtlán, and Cuicatlán of Oaxaca, about 17°30′N. Collections come from elevations of 1,000–2,150 m.

Common name. Cabellito de angel (Hidalgo).

CULTIVATED: U.S.A., Missouri, St. Louis, Missouri Botanical Garden, *H. Hernández 951* (MEXU, MO).

This morphologically plastic species is widespread in dry and semiarid regions of central and northern Mexico. It can be readily distinguished from its close relative *Z. alinae* primarily by having larger, white/purple-red filaments, usually shorter stature, and copious branching. In addition, the leaflets of *Z. media* are usually broader than those of *Z. alinae*. The relationship between these two species is discussed further under *Z. alinae*.

As shown in Figure 32, most of the known populations consist of plants with leaves glabrous or ciliate and very sparsely pilose on the rachis and rachilla. Plants with pubescent or pilose leaflets have been collected primarily in restricted areas in the southern part of its range (Oaxaca, Puebla, Hidalgo, Guanajuato, San Luis Potosí, and Tamaulipas). Most of the collections with hairy leaflets are concentrated west of Hidalgo (Fig. 32), where Galeotti collected the type. With the exception of a population from the Barranca de Tolimán, Mpio. Zimapán, Hidalgo, where plants with hairy and with glabrous leaflets have been collected (*H. Hernández & Torres 157*, *Moore 1383*), populations of plants with hairy leaflets seem to be geographically segregated from the glabrous ones.

The distributions of *Z. media* and *Z. formosa* approach one another closely in some areas of northern Oaxaca and southern Puebla, but individuals from these species are not known to grow together. There is evidence of hybridization, which results in morphological intergradation between the two. Plants collected in the area of Acatlán de Osorio and Tehuitzingo, Puebla (*H. Hernández & Torres 192*, *Miranda 2921*, *2918*, *Sousa et al. 9804*), and Cuicatlán and Nochixtlán, Oaxaca (*Conzatti 1929*, *Miranda 1717*) have characteristics (e.g., hairy leaflets, fewer pairs of leaflets per pinna, and broader leaflets) that differ from those typical of *Z. media* and tend to approximate those of *Z. formosa* subsp. *mollicula* or subsp. *rosei*.

3. Zapoteca alinae H. Hern., sp. nov. TYPE: Mexico. Oaxaca: Distrito Tlacolula, 6 km NE de Mitla por camino a Albarradas, 1,690 m, veg. matorral xerófito muy alterado, 1 Aug.

1983, *H. Hernández & R. Torres 206* (holotype, MEXU; isotype, MO). Additional isotypes to be distributed. Figure 33.

Frutices recti caulibus valde gracilibus omnino glabris vel fere glabris. Pinnae 1-jugae, interdum 2- vel 3-jugae; foliola 16 19-juga in pinna utraque augusto-oblonga vel lanceolata, venatione inconspicua. Capitula axillaria raro in pseudopaniculis brevibus simplicibusque disposita. Flores filamentis albis praediti. Legumina crassa, membranacea glabra. Numerus chromosomatum somaticus $2n = 26$.

Shrubs to 4 m high; stems very slender, to ca. 1.5 cm diam. at the base, the bark smooth; branchlets terete, costate under magnification, dark, more or less lustrous, glabrous. Pinnae 1(3)-jugate; petiole eglandular, terete, 0.9–3.7 cm long, glabrous; rachis 3–10 mm long in leaves with 2 or more pairs of pinnae, glabrous; rachillae 1.7–4 cm long

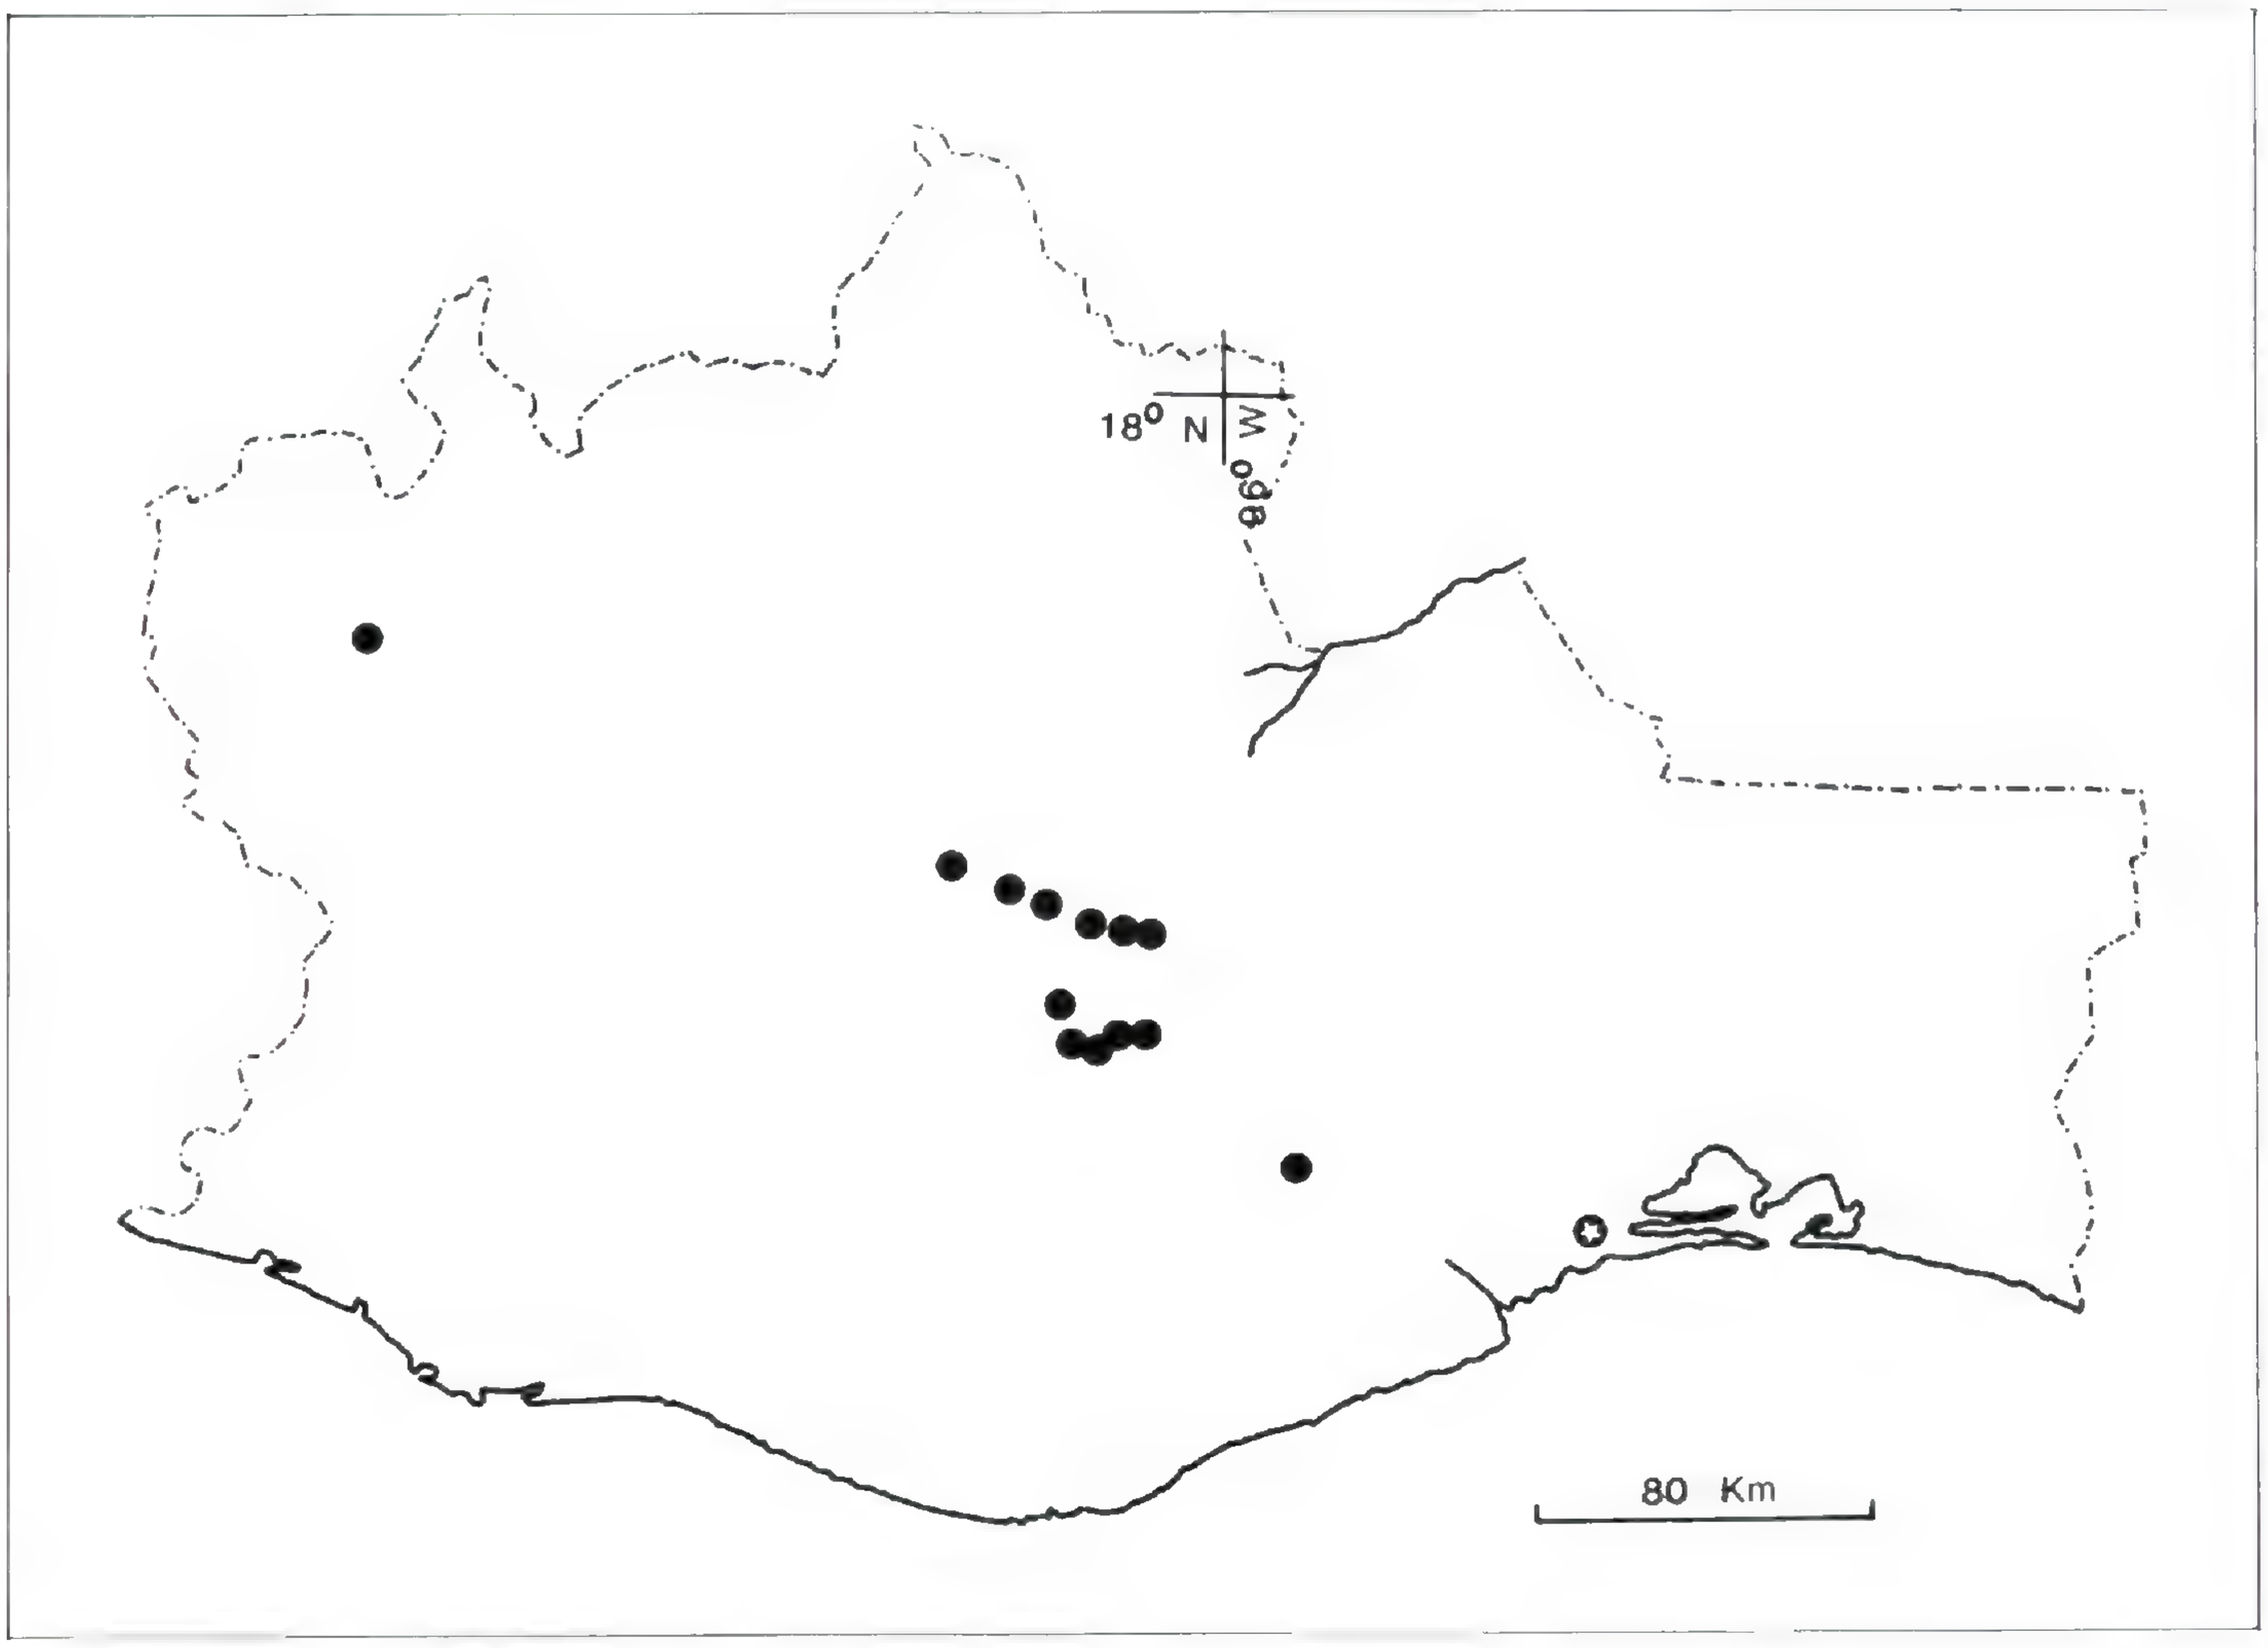

FIGURE 34. Map of Oaxaca, Mexico, showing the distribution of *Zapoteca alinae* (dots) and *Z. tehuana* (dot with star).

in well-developed leaves; leaflets 16–19 pairs per pinna, narrowly oblong to lanceolate, at base strongly oblique, at apex rounded or acute, usually mucronulate, 4 12 × 1–2.5 mm, membranous, glabrous, sometimes ciliolate; leaflet venation inconspicuous; stipules leafy, narrowly triangular to lanceolate, 2–3 mm long, glabrous. Capitula axillary, rarely also in simple pseudopanicles 1.5–4 cm long; peduncles solitary or fasciculate, filiform, 2.5–6.5 cm long at anthesis. Flowers ca. 15 25 per capitulum; the calyx ca. 2 mm long, the teeth ovate-lanceolate, acute at apex, mucronulate, glabrous; corolla campanulate, ca. 4 mm long, the lobes ovate to narrowly ovate, acute at apex, glabrous; filaments 15 20 mm long, white, the staminal tube ca. 1 mm long; ovaries ca. 1.2 mm long, on occasion 2 in a single flower, glabrous; style ca. 16 mm long. Pods to 10 × 0.8 cm when mature, at apex rounded, rostellate, thick-membranous, glabrous. Seeds widely rhomboid to widely ovoid, flattened, grayish or darker, ca. 5 × 4 mm; pleurogram irregular, usually demarcated by a dark line. Somatic chromosome number $2n = 26$.

Distribution (Fig. 34). Essentially endemic to central Oaxaca, in the districts of Tlacolula, Yautepec, Centro, Miahuatlán, and Teposcolula. *Zapoteca alinae* grows mainly on steep, rocky slopes in tropical deciduous and thorn forests and in secondary vegetation derived from these vegetation types; it has also been collected along seasonal streams. Collections come from elevations of 1,050 1,800 m.

Common name. Barba de chivo.

Additional specimens examined. MEXICO. OAXACA: Dist. del Centro, Cerro del Tule, *Conzatti 5474* (NY); 5 km SW Miahuatlán, *García 1607* (MEXU); Dist. Tlacolula, a 7 km NE de Mitla por carr. a Tamazulapan, *H. Hernández & Torres 271* (MEXU, MO); Dist. Tlacolula, 11 km E-NE de Totolapan por carr. a Tehuantepec, *H. Hernández & Torres 280* (MEXU, MO); Dist. Tlacolula, 33 km de San José de Gracia sobre carr. Tehuantepec Oaxaca, entre San José de Gracia y San Juan Guegoyache, *H. Hernández & Ramírez 939* (MEXU, MO); Dist. Tlacolula, 7 km NW de Totolapan por carr. a Oaxaca, *H. Tlacolula, 3 km NE San Bartolo Albarradas, 19 km E-NE Mitla, *Sousa et al. 7846* (MEXU, MO); Dist. Tlacolula, 11 km E-NE Totolapan, *Sousa & Téllez 8565* (CAS, ENCB, MEXU, MICH); Dist. Yautepec, 1 km S El Laurel,

carr. Est. Microndas, *Sousa & Téllez 8611* (MEXU, MO); Dist. Teposcolula, Las Pilas, a 4 km al E de Tamazulapan, *Sousa et al. 8991* (MEXU, MO); Dist. Tlacolula, 16 km N Totolapan, *Sousa et al. 9424* (ENCB, MEXU); Dist. Tlacolula, 6 km N de Mitla, carr. a Totontepec, *Torres et al. 3947* (MEXU, MO); Dist. Yautepec, Torre de Microondas, San Cristóbal, al W de Portillo Nejapa, *Torres & Martínez 7449* (MEXU).

This endemic species, which is relatively consistent morphologically, is closely allied to *Z. media* by its 1- to 3-jugate pinnae, small, numerous leaflets, and habitat preferences. It can be readily distinguished from that species by the usually more slender stems, branchlets, and peduncles, narrower and consistently glabrous leaflets, and primarily by its flowers with shorter, white filaments. *Zapoteca alinae* is allopatric with *Z. media*. Its distribution overlaps at the east of its range (*H. Hernández & Torres 942*) near Totolapan, Dist. Tlacolula, with that of *Z. formosa* subsp. *rosei* (*H. Hernández & Torres 943*), but no evidence of hybridization was observed there.

4. Zapoteca lambertiana (G. Don) H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. *Acacia lambertiana* G. Don, Edward's Bot. Reg. 9: t. 721. 1823. *Calliandra lambertiana* (G. Don) Benth., London J. Bot. 3: 100. 1844. Benth., Trans. Linn. Soc. London 30: 543. 1875. *Feuilleea lambertiana* (G. Don) Kuntze, Revis. Gen. Pl. 188. 1891. *Anneslia lambertiana* (G. Don) Britton & Rose, N. Amer. Fl. 23: 66. 1928. TYPE: Mexico: locality unknown, cultivated by George Don from material sent to him by Mr. Lambert from Boyton, where plants of this species had been raised from seeds collected in Mexico (lectotype, K; Hernández, Ann. Missouri Bot. Gard. 73: 757. 1986).

Erect shrubs to 4 m tall; stems slender; branchlets terete, costate under magnification, glabrous to villous or pilose. Pinnae (1–)2–4-jugate, rachis usually eglandular, rarely with small (ca. 0.3 mm diam.), cup-shaped, slightly elevated glands between the basal pairs of pinnae, the proximal pairs of pinnae rarely alternate; petiole terete, with a conspicuous adaxial channel, (1.2–)1.5–4.6 cm long, glabrous, rarely villous or pilose; rachis of 2-jugate pinnae (0.2–)0.4–1.8 cm, much longer when 3- or 4-jugate, glabrous to villous; rachillae 2.4–6.4(–7.5) cm long; leaflets (6–)7–17(–22) pairs per pinna, narrowly oblong to oblong or oblong-ovate, occasionally lanceolate, at base oblique, at apex acute, the median ones 8–14(16) × 2.5 4(–5) mm, the proximal ones smaller, membranous, all glabrous to villous or puberulent on both surfaces, occasionally hairy only abaxially, sometimes ciliate; leaflet venation visible superficially; stipules leafy, triangular-lanceolate to ovate, acute at apex, striate, 2–8 mm long, glabrous to sparsely villous. Capitula axillary, or more commonly arranged in compound or most commonly simple pseudopanicles 3.5–9.5 cm long; peduncles fasciculate at distant nodes, (0.5)1.5–6.5 cm long at anthesis, glabrous. Calyx ca. 2 mm long, glabrous, sometimes ciliolate, the teeth narrowly oblong or triangular, acute at apex; corolla campanulate, 3–4 mm long, glabrous, the lobes narrowly elliptic, acute at apex; filaments ca. 2.5 cm long, red-purple, the staminal tube 1–1.5 mm long; ovary sessile, glabrous. Pods to 9 × 1 cm when mature, rounded, retuse or acute at apex, rostellate, membranous, glabrous. Seeds quadrate-rhomboid to very widely ovoid, 3.5–4 × 3–3.5 mm, dark brown, the areola lighter; pleurogram irregular.

Distribution (Fig. 35). *Zapoteca lambertiana* has been collected primarily in tropical dry forests and less commonly in tropical thorn, tropical subdeciduous, or tropical evergreen forests, where it usually is associated with secondary vegetation. It is distributed discontinuously from northeastern to southeastern Mexico, where a series of disjunctions occur. Most collections have been made in the following regions: 1) Sierra de Tamaulipas, Tamaulipas; 2) Region of Villa Juárez and Huasteca, San Luis Potosí; 3) Coastal Plain of the Gulf of Mexico, east and northeast of Xalapa, Veracruz; 4) Region of Los Tuxtlas, Veracruz; and 5) Slopes of the Central Depression of Chiapas. Collections come from altitudes of 190 900 m.

Common names. Barba de chivo (Tamaulipas), t'sak xiixit (Huasteca).

Additional specimens examined. MEXICO. CHIAPAS: Mpio. Cintalapa, Rizo de Oro, *Breedlove 36732* (DS, MEXU, MICH, NY); Mpio. Chicoasén, above Chicoasén, *Breedlove 37255* (DS, MEXU, TEX); Mpio. Zapoteca lambertiana can be readily distinguished from other species of subg. *Zapoteca* primarily by its much thinner pods with undulate surfaces and thinner margins, and specifically from *Z. portoricensis* by its red-purple filaments. Extrafloral nectaries between the pinnae in a single specimen (*Dressler 2006*, GH) and presumed similarities in the texture of the pods suggest a possible close relationship between this species and *Z. filipes*. Leaf indument is very variable in *Z. lambertiana*; it varies at both intra- and interpopulation levels and does not seem to follow a geographical pattern.

There is no morphological differentiation among the disjunct populations that occur over the extensive geographical range of *Z. lambertiana*. It is likely that such discontinuities are of recent origin. Perhaps they resulted from tropical dry

forest fragmentations that occurred in the tropics subsequent to the Pleistocene glaciation, after the present wetter conditions originated disjunctions in the formerly extensive and continuous areas covered by tropical dry forests.

5. Zapoteca filipes (Benth.) H. Hern., comb. nov. *Calliandra filipes* Benth., J. Bot. (Hooker) 2: 139. 1840; Benth., Lond. J. Bot. 3: 99. 1844; Benth., Trans. Linn. Soc. London 30: 542. 1875; Benth. in C. Martius, Fl. Bras. 15(2): 412. 1876; J. F. Macbr., Field Mus. Nat. Hist., Ser. Bot. 13: 71. 1943; L. Cárdenas, Revista Fac. Agron. (Maracay) 7: 131. 1974. *Feuilleea dimidiata* Kuntze, Revis. Gen. Pl. 185. 1891. (This was published as a nomen novum because the name *F. filipes* was preoccupied by a species based on *Inga felipes*.) TYPE: Brazil: *Pohl 1458* (lectotype, K, here designated; isolectotype, K).

Erect shrubs to 2 m tall; branchlets terete, costate under magnification, sparsely villous, becoming glabrous. Pinnae 4–5-jugate; petioles terete to subtetragonal, with a conspicuous adaxial channel, 2–3.5 cm long, glabrous to sparsely villous; rachis 2.5–4.5(–7.5) cm long; rachillae 2.5–5.5(–7) cm long; with glands near the base of the petiole, at the insertions of the pinnae, and usually at the insertions of the leaflets, these cylindrical, concave at apex, to ca. 1 cm long but usually smaller; leaflets (9–)11–16 pairs per pinna, mostly falcately oblong-lanceolate, oblique at the base, at apex rounded to acute, mucronulate, 8–14 × 2.5–5 mm, membranous, glabrous or at most sparsely ciliate; primary and secondary leaflet veins conspicuous, especially abaxially; stipules leafy, lanceolate, parallel-veined, usually 3–5 mm long, glabrous. Capitula axillary; peduncles fasciculate, (3.5–)4.5–8 cm long at anthesis, glabrous. Flowers basically pentamerous but the number of flower parts variable; calyx ca. 2 mm long, glabrous, the teeth irregular, triangular or narrowly oblong, acute at apex; corolla campanulate, ca. 4 mm long, glabrous, the lobes lanceolate; filaments white in the basal half and red-purple in the distal half, the staminal tube ca. 2 mm long; ovary 1.5–2 mm long, sessile, glabrous. Pods ca. 7.5 × 0.7 cm when mature, at apex truncate, rostellate, membranous, glabrous.

Distribution. This species has been collected at a few localities in the Brazilian states of Goiás and Minas Gerais, where it is commonly associated with cerrado vegetation at 950 m elevation. It was incorrectly reported by Macbride (1943) from Peru and by Cárdenas (1974) from Venezuela.

Additional specimens examined. BRAZIL. MINAS GERAIS: Sierra do Espinhaço, ca. 5 km NE Francisco Sá, road to Salinas, *Irwin et al. 23205* (K); BR-4 entre km 810 811, *Pabst & Pereira 9414* (NY). GOIÁS: Salgado, *Pohl 3492* (F, NY).

Zapoteca filipes is probably closely related to *Z. lambertiana* as judged by the vegetative characteristics of these species, especially by the common possession of membranous pods. Extrafloral nectaries, universal in *Z. filipes*, are occasional in *Z. lambertiana*. *Zapoteca filipes* can be readily distinguished from the remaining species of subg. *Zapoteca* by the cylindrical glands on the petiole, rachis, and rachillae.

6. Zapoteca portoricensis (Jacq.) H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. *Mimosa portoricensis* Jacq., Collectanea 4: 143. 1791; Jacq., Icon. Pl. Rar. 3: 20, t. 633. 1793. *Acacia portoricensis* (Jacq.) Willd., Spec. 4: 1069. 1806; DC., Prodr. 2: 467. 1825; Schldl. & Cham., Linnaea 5: 595. 1830; G. Don, Gen. Hist. 2: 419. 1832; Schldl., Linnaea 12: 566. 1838. *Calliandra portoricensis* (Jacq.) Benth., London J. Bot. 3: 99. 1844; Benth., London J. Bot. 5: 102. 1846; Griseb., Fl. Brit. W. Ind. 224. 1860; Benth., Trans. Linn. Soc. London 30: 543. 1875; Benth. in C. Martius, Fl. Bras. 15: 411. 1876; Standley, Publ. Field Mus. Nat. Hist., Bot. Ser. 18: 492. 1937; Standley & Calderón, Fl. Salvadoreña 125. 1941; J. F. Macbr., Field Mus. Nat. Hist., Bot. Ser. 13: 72. 1943, pro parte; Standley & Steyerm., Fieldiana, Bot. 24: 25. 1946; L. Cárdenas, Revista Fac. Agron. (Maracay) 7: 131. 1974. *Feuilleea portoricensis* (Jacq.) Kuntze, Revis. Gen. Pl. 184. 1891. *Anneslia portoricensis* (Jacq.) J. D. Smith, Enum. Pl. Guat. 2: 18. 1891. TYPE: Puerto Rico: *Bredemayer 16* (neotype, B-W, here designated, seen on microfiche). Although there is no direct evidence, it is likely that the Bredemayer specimen collected in Puerto Rico, and here designated as the neotype was used by Jacquin as a basis for his description of *Mimosa portoricensis*. Bredemayer participated in two of the Austrian botanical expeditions to the West Indies in 1783–1785 and 1785–1788, which provided materials for Jacquin to use in his *Collectanea* and other works. In connection with this, D'Arcy (1970) pointed out that "it is likely that Jacquin based many of his descriptions of new species on plants brought in by the official Austrian bo-

tanical expeditions and grown in Austrian gardens."

Erect or scandent shrubs usually to 3(7) m tall; stems slender, sometimes to 12 cm diam. at base; branchlets terete, occasionally 4-angled or nearly so, glabrous to very densely villous with white or tawny hairs, usually becoming glabrate. Pinnae (1)3 6(–8)-jugate; petioles eglandular, usually angulate or 4-angled, (1–)2–5 cm long, villous to densely villous, rarely glabrous; rachis 0.9 5.5(–10) cm long; rachilla (2)3–9.5(11) cm long; leaflets (8–)15 67 pairs per pinna, narrowly oblong to lanceolate or oblong to oblong-obovate, occasionally subfalcate, oblique at base, acute to rounded at apex, usually mucronulate, the median leaflets 4–20 × 1 6 mm, membranous, either glabrous, villous, puberulent, or sericeous on both surfaces, usually ciliate; leaflet venation inconspicuous; stipules leafy, adpressed, triangular to triangular-lanceolate, occasionally linear-triangular, sometimes slightly curved, to 11(17) mm long, glabrous to densely villous. Capitula usually axillary, occasionally arranged in pseudopanicles to 20 cm long; peduncles fasciculate, (1.3–)3–12(–15) cm long at anthesis. Flowers pentamerous, rarely tetramerous; calyx cup-shaped, 1 3(3.5) mm long, glabrous to ciliate or densely villous around the teeth, these usually triangular to deltate, sometimes lanceolate to linear-lanceolate or narrowly oblong, acute; corolla campanulate, 3 8(10) mm long, glabrous, occasionally villous apically, the lobes lanceolate; filaments ca. 2.5 cm long, white, the staminal tube ca. 2 mm long; ovary ca. 1.5 mm long when fertile, glabrous, sessile. Pods linear, rarely slightly curved, the apex rounded to truncate, rostellate, to 16.5 cm long when mature, thickly membranous, glabrous or puberulent. Seeds widely rhomboid to very widely ovoid, 5–7 × 3–5 mm, brown, dark brown, or black, the areola sometimes mottled; pleurogram irregular, sometimes regular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 36). Frequent in open sites such as forest clearings, forest edges, roadsides, river banks, and wet thickets; in general in secondary habitats derived from a variety of vegetation types. Collections come from elevations of 0–2,100 m. Standley (1930) incorrectly included this species in the *Flora of Yucatán*.

Zapoteca portoricensis as circumscribed here, consists of three rather variable subspecies: *portoricensis*, *pubicarpa*, and *flavida*. Each has a few distinguishing, variable characters (Table 12), although they intergrade and overlap. Consequently, these subspecies are defined on the basis of combinations of characters. Viewed in a local context, each subspecies might be accorded specific rank; however, a synthetic analysis of all available material reflects the absence of strong morphological discontinuities distinguishing them.

The three subspecies of *Z. portoricensis* have distinct habitat preferences: subsp. *portoricensis* occurs primarily in relatively wet, mid- to high-altitude habitats; subsp. *flavida* is found in wet, lowland areas; and subsp. *pubicarpa* occurs in dry, mid-altitude areas. However, in the West Indies, subsp. *portoricensis* usually occurs in much drier, low, sometimes coastal, habitats.

KEY TO THE SUBSPECIES OF *ZAPOTECA PORTORICENSIS*

1a. Shrubs scandent; leaflets 7 20 × 2 6 mm; corolla 3–4 mm long; mature pods to 16.5 cm long ..... 6c. subsp. *flavida*

1b. Shrubs erect; leaflets 4–12(–15) × 1–3 mm; corolla 4–8(–10) mm long; mature pods to 12 (14.5) cm long.

2a. Pods glabrous, rarely hairy; peduncles (1.8)3.5–12(–15) cm long at anthesis; calyx glabrous to ciliate, the teeth rarely sparsely villous; corolla 4–8 mm long ..... 6a. subsp. *portoricensis*

2b. Pods puberulent; peduncles 1.3–3.5(6) cm long at anthesis; calyx teeth consistently villous; corolla 7–8(–10) mm long ..... 6b. subsp. *pubicarpa*

6a. Zapoteca portoricensis (Jacq.) H. Hern. subsp. **portoricensis.**

Lysiloma marchiana Griseb., Fl. Brit. W.I. 223. 1860. TYPE: Jamaica, *March s.n.* (holotype, GOET (not seen); isotypes, GH, NY).

Calliandra nicaraguensis Taub. & Loes. ex Loes., Bot. Jahrb. Syst. 23: 124. 1897. *Anneslia nicaraguensis* (Taub. & Loes. ex Loes.) Britton & Rose, N. Amer. Fl. 23: 63. 1928. TYPE: Nicaragua. Matagalpa: Cañada Yasica, 1,000 m, 4 Aug. 1843, *Rothschuh 204* (lectotype, US no. 1266103 (fragment and photo), here designated; isolectotype, NY (fragment)). The holotype, which was at B, was destroyed in 1943 (P. Hiepko, pers. comm., 1986); photos of this specimen are at F, MEXU, MO, NY, TEX, US.

Calliandra portoricensis var. *major* Sprague, Bot. Mag. 133: t. 8129. 1907. TYPE: Cult. in Hort. Bot. Reg. Kew, Aug. 1906 (lectotype here designated, K), this specimen was presumably collected by Sprague.

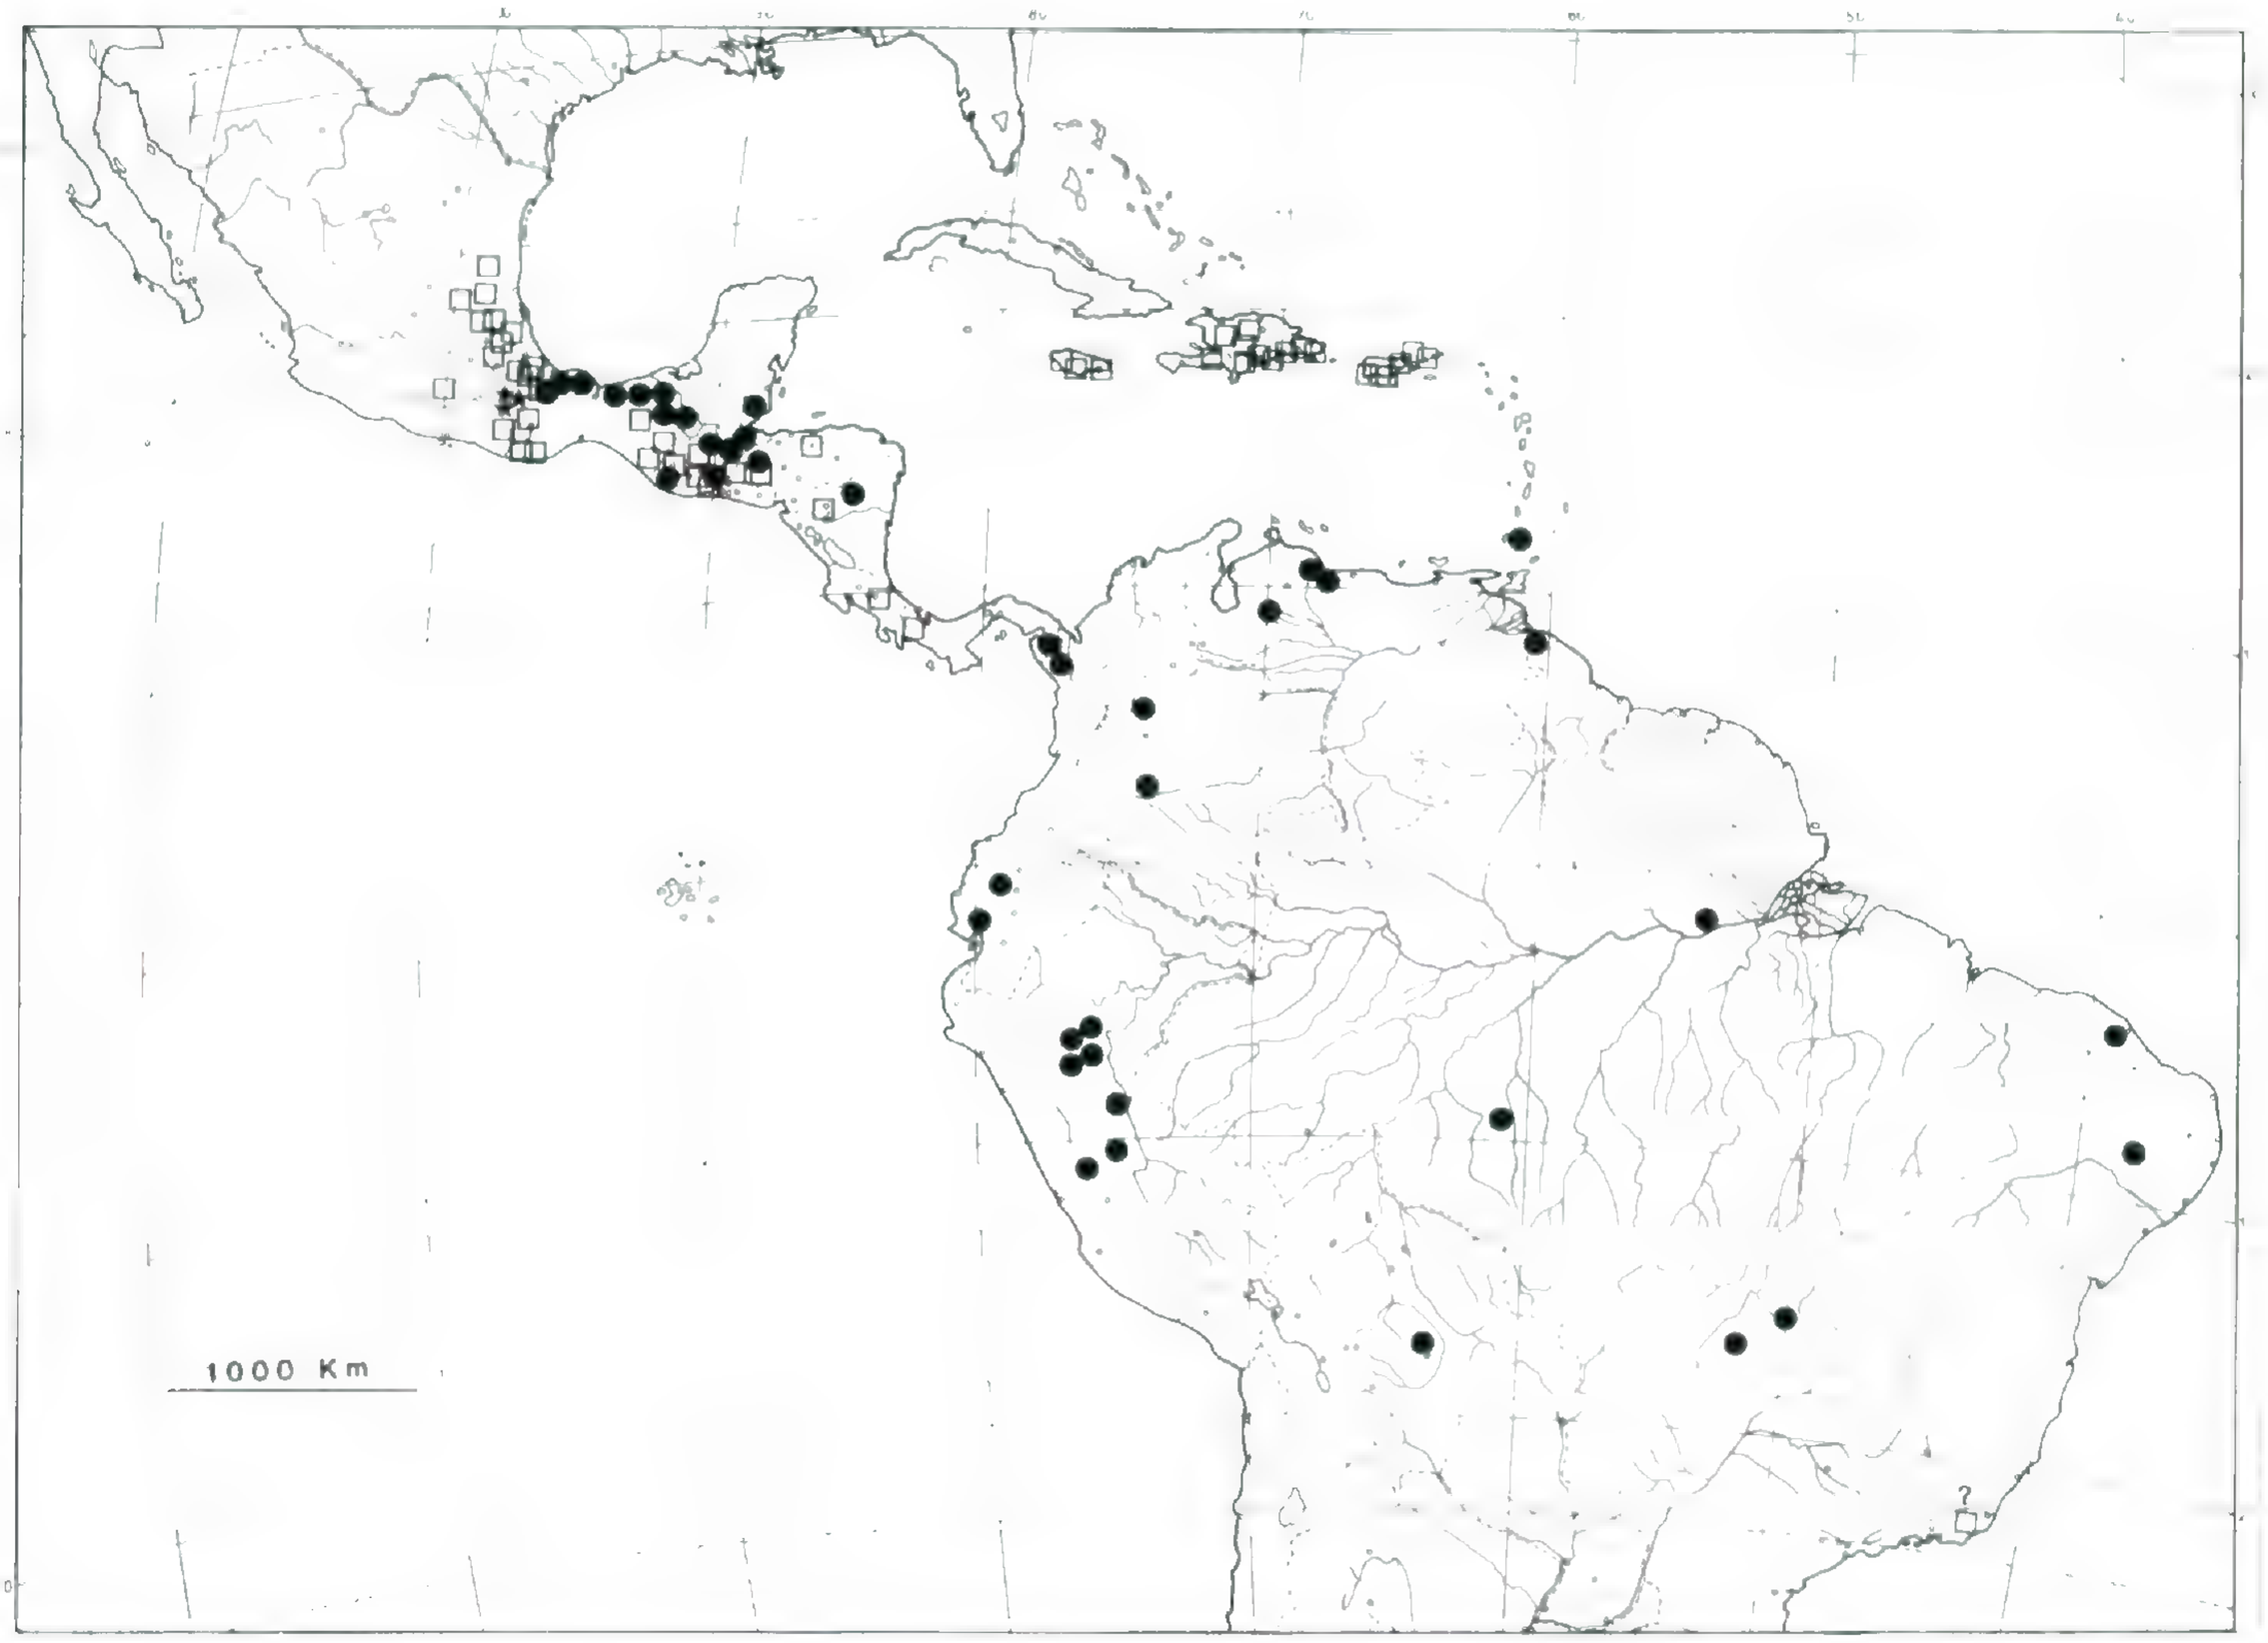

FIGURE 36. Distribution of *Zapoteca portoricensis* subsp. *portoricensis* (open squares), *Z. portoricensis* subsp. *pubicarpa* (stars), and *Z. portoricensis* subsp. *flavida* (dots).

Sprague mentioned in his discussion that "the Kew plants were purchased in 1906 from a nursery-man in Hyères as 'Inga alba' and flowered in the Temperate House in June and July of that year."

Anneslia spraguei Britton & Rose, N. Amer. Fl. 23: 66. 1928. *Calliandra spraguei* (Britton & Rose) Lundell, Lloydia 2: 89. 1939. TYPE: Mexico. Veracruz: Xalapa, *Schiede 690* (lectotype here designated, NY; isolectotypes, BM, CAS, CGE, G, GH, K, LE, MEXU, MO, UC, US—fragment). The specimens at NY and K are the only ones labeled as collections made by "*Schiede 690*," whereas the specimens at LE and MO are labeled "*Schiede and Deppe 690.*" The specimens from BM and G are labeled "*Schiede*

TABLE 12. Comparison of the subspecies of *Zapoteca portoricensis*.

	Subspecies *portoricensis*	Subspecies *pubicarpa*	Subspecies *flavida*
Habit	erect shrubs	erect shrubs	scandent
Pairs of pinnae	(1)2 7(8)	2 4	(2)3–5(7)
Leaflet			
Shape	narrowly oblong to lanceolate	narrowly oblong to lanceolate	oblong to oblong-lanceolate
l × w	5–15 × 1 3 mm	4–7 × 1–2 mm	7 20 × 2 6 mm
Pairs pinna	(12–)16–67	15 30	(8)18 36
Stipule length	10(17) mm	11 mm	11(13) mm
Peduncle length	(1.8)3.5 12(–15) cm	1.3–3.5(6) cm	3 7.5 cm
Calyx			
Length	1 3 mm	2–3(–3.5) mm	1 2 mm
Indument	glabrous to ciliate	villous to densely villous	glabrous
Corolla length	4–8 mm	7–8(10) mm	3 4 mm

Length	12(–14.5) cm	6–7 cm	16.5 cm
Indument	glabrous	puberulent	glabrous

and Deppe" (*s.n.*), and the one at UC is labeled "*Schiede*" (*s.n.*). The specimens at CAS, CGE, GH, and MEXU do not have any reference to collector, although records from the last herbarium make reference to this specimen as collected by Schiede. With the exception of three (BM, MEXU, and UC), all the collections are hand annotated as "*Acacia portoricensis* Willd.," and judging from the handwriting, the other data provided, and the aspect of the plants, all these specimens almost certainly are duplicates of the same *Schiede 690* collection. The specimens at G, GH, and NY have a mark, presumably made *a posteriori*, with the name "Schlech."; nevertheless, it is well known that Schlechtendal never traveled outside Western Europe, although a number of collections from Mexico have mistakenly been attributed to him. According to R. Barneby (pers. comm.), Schlechtendal distributed Schiede's plants.

Calliandra nogalensis Lundell, Lloydia 2: 88. 1939. TYPE: México. Veracruz: Nogales, *E. Matuda 1153*, 2 May 1937 (holotype, MICH; isotypes, F, MEXU, NY).

Calliandra siltepensis Lundell, Phytologia 2: 1. 1941. TYPE: Mexico. Chiapas: Barranca Honda, Siltepec, Oct.–Nov. 1940, *E. Matuda 4040* (holotype, MICH; isotypes, A, F, MEXU, NY).

Erect shrubs, 2–3(6) m tall; stems slender, sometimes to 12 cm diam. at the base; branchlets terete, sometimes 4-angled, glabrous to densely villous with tawny hairs, often glabrate. Pinnae (1)3–7(–8)-jugate; leaflets (12–)16 67 pairs per pinna, narrowly oblong to lanceolate, rarely oblanceolate, oblique at the base, acute to rounded at the apex, usually mucronulate, 5 15 × 1–3 mm, glabrous to villous, puberulent, or sericeous on both surfaces, usually ciliate; stipules triangular to narrowly triangular, sometimes slightly curved, 10 (–17) mm long, glabrous to villous. Capitula axillary; peduncles (1.8 -)3.5–12(15) cm long at anthesis, glabrous to densely villous. Calyx 1–3 mm long, the teeth usually triangular, sometimes lanceolate to linear-lanceolate, usually glabrous or ciliate, sometimes with a few hairs in the area of the teeth; corolla 4–8 mm long, glabrous. Pods to 12(–14.5) × 1(–1.2) cm, straight or slightly curved, glabrous. Seeds widely rhomboid to ovoid, 5–7 × 3–5 mm, brown to black, the areola sometimes mottled; pleurogram usually irregular, sometimes regular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 36). This widespread subspecies has been collected in several relatively localized areas: 1) Atlantic slopes of the Sierra Madre Oriental, in the states of Hidalgo, Puebla, and San Luis Potosí, and the eastern portion of the Transverse Volcanic Belt in Veracruz; 2) Sierra Madre del Sur, including parts of the Mixteca Region in Oaxaca; 3) Sierra Madre of Chiapas, and the Chiapas and Guatemala Highlands; and 4) West Indies, in Jamaica, Hispaniola, and Puerto Rico (including some of the Virgin Islands). Disjunctions occur in the Sierra de Tamaulipas, Tamaulipas; Temascaltepec, State of México; and in Honduras, Nicaragua, Costa Rica, and Panamá. There is a collection from Nova Friburgo, Rio de Janeiro, Brazil (*Curran 655*), which was probably obtained from cultivated plants. This subspecies has usually been collected in mountain areas of moderate to relatively high altitude (800–2,100 m), in plant communities such as oak, pine, pine–oak, temperate deciduous, wet montane cloud, and montane rain forests, especially in secondary habitats. Nevertheless, in some areas such as the Huasteca in the states of Hidalgo and San Luis Potosí, Mexico, populations usually occur at lower elevations, reaching as low as 165 m. Similarly, plants from the West Indies usually inhabit low elevation areas, down to sea level, with a much drier climate.

Common names. Barba de chivo (Nicaragua), carboncillo blanco (Costa Rica), granolino (Dominican Republic), guacamaya montés (El Salvador), guaje cimarrón (Veracruz), guajillo (Veracruz), guajillo blanco (Veracruz), night-flowering acacia (Jamaica), pelo de angel (Puebla, San Luis Potosí), tamarindo de monte (Guatemala), timbrillo (Veracruz), white tamarind (Guatemala, Jamaica).

Additional specimens examined. MEXICO. CHIAPAS: 21 km al este de las Lagunas de Monte Bello, *Cabrera 3690* (MEXU, MO); El Chorreadero, 5.6 mi. east of Chiapa de Corzo, *Breedlove 11889* (CAS, LL, MICH, MO, US); Mpio. of Motozintla de Mendoza, SW side of Cerro Mozotal, *Breedlove 25917* (CAS, MEXU, MICH, MO, NY); Mpio. of Zinacantán, Paraje Granadilla, *Laughlin 1069* (CAS, MICH, US); Ovando, *Matuda 17923* (F, MEXU, NY); Escuintla, El Triunfo, *Matuda 18098* (CAS, MEXU, NY); Siltepec, Cascada, *Matuda 18666* (CAS, MEXU, NY). As shown above, there are several names that have been included among the list of synonyms of *Z. portoricensis* (e.g., Bentham, 1875; Britton & Rose, 1928). However, I have been unable to associate any relevant specimens with these epithets. *Acacia venusta* Willd. (Enum. Hort. Berol. 1052. 1809) has been traditionally included in synonymy under *Z.* (*Calliandra*) *portoricensis*, which is probably incorrect. The only material I have been able to relate to this name is a specimen at the Willdenow Herbarium (Cat. No. 19143), which comes from "Hort. Bot. Berol. W.," as indicated by a handwritten note in the lower right margin. The brief description provided in the original publication of this species is a replica of the specimen label, which probably was handwritten by Willdenow himself, judging by the style of handwriting (Burdet, 1979). This specimen consists of two leaves, with the pinnae widely separate from each other, and rather few pairs of leaflets per pinnae. Because of the lack of flowers or pods, it is not possible to relate this specimen to *Z. portoricensis*.

Zapoteca portoricensis subsp. *portoricensis*, as delimited here, is an extremely variable, broadly defined subspecies, the most variable within the species. It can be distinguished from closely related subsp. *pubicarpa* by its glabrous pods, usually smaller flowers, glabrous to ciliate calyx teeth, and usually longer peduncles (Table 12). It differs from subsp. *flavida* by its erect habit, usually smaller and more numerous leaflets, usually larger flower parts, and smaller pods (Table 12).

Perhaps the most highly variable character in subsp. *portoricensis* is the degree of pubescence of its vegetative structures. Plants range from entirely glabrous or glabrate to having branchlets and leaf parts densely villous with long tawny hairs. This type of variation occurs at both inter- and intrapopulational levels, and, consequently, is of little taxonomic value. There are geographical patterns in the expression of this character. One extreme occurs in Veracruz, and to a lesser extent in Hidalgo and Chiapas, where there is a prevalence of collections with densely villous branchlets and leaves. The other extreme occurs in San Luis Potosí, Tamaulipas, and Central America, where glabrous or sparsely villous leaves and stems predominate. In the West Indian plants, the leaflets are consistently glabrous, but the branchlets may be villous or glabrous.

Other variable characters in *Z. portoricensis* subsp. *portoricensis* are the size and number of pairs of leaflets per pinna. Most plants from the Sierra Mixteca, Sierra Madre del Sur, and Sierra Madre de Chiapas, in the states of Oaxaca and Chiapas, Mexico, are characterized by pinnae with smaller, more numerous (to 67) pairs of leaflets usually densely distributed along the rachilla, giving the pinnae a feathery aspect. Plants with small, numerous pairs of leaflets per pinna are also found in Central America. In Oaxaca, plants with leaves

of this sort also tend to have larger flowers and usually larger stipules. However, these characters have been found in numerous collections from different regions (e.g., Veracruz, Puebla, Hidalgo), where they occur in plants that do not have feathery leaves like the ones in Oaxaca, so that there is no definite geographical pattern and no basis for recognizing additional infraspecific taxa. In contrast, many of the plants from the West Indies have larger and less numerous leaflets, thereby resembling subsp. *flavida*.

The vast majority of collections of *Z. portoricensis* subsp. *portoricensis* have terete branchlets; however, plants with four-angled branchlets, a characteristic diagnostic for *Z. tetragona*, are not uncommon in some regions. Some of these plants may be the result of hybridization between subsp. *portoricensis* and *Z. tetragona*. These two taxa are generally ecologically isolated in Central America and southern Mexico, where their geographical ranges overlap. In these regions, populations of subsp. *portoricensis* are found primarily in montane cloud forest or similar habitats, whereas those of *Z. tetragona* occur in warmer lowland habitats. Populations with four-angled branchlets are most frequent in Guatemala, where these two taxa come into close proximity and in some cases are probably strict sympatric. A number of Guatemalan collections of subsp. *portoricensis* have four-angled branchlets, although sometimes this characteristic is expressed only distally, or is less marked than in typical *Z. tetragona* (e.g., *Molina & Molina 12287*, *Standley 86574*, *87132*, *Steyermark 34256*, *Williams et al. 12100*, and others). Significantly, these plants are derived from areas where *Z. portoricensis* subsp. *portoricensis* and *Z. tetragona* approach each other, as for example, in the areas of San Juan Chamelco–Cobán–San Pedro Corchá, Departamento de Alta Verapaz; Colomba Santa María de Jesús, Departamento de Quetzaltenango; Ipala–Comatán, Departamento de Chiquimula; and Escuintla–San Vicente Pacayas, Departamento de Escuintla. Individuals with four-angled branchlets also occur in some other regions (e.g., Orizaba Cordoba, Veracruz, Chiapas), and even in areas where *Z. tetragona* does not occur, such as Haiti.

West Indian populations often differ from those on the mainland in some characters, possibly the result of the smaller gene pools in insular populations and the selective effects of local climates. In many of the plants collected in the West Indies, the leaflets are comparatively larger, approximating those of *Z. portoricensis* subsp. *flavida*. Jamaican specimens are characterized by smaller (4.5–6 cm long) pods and by usually smaller, black seeds with regular pleurograms, as compared with the mainland populations. In addition, some of the plants from this island have 1–2-jugate pinnae with fewer pairs of leaflets.

Zapoteca portoricensis subsp. *portoricensis* and its close relative *Z. caracasana* subsp. *caracasana* co-occur on Hispaniola, although it is unclear whether they really grow together. Here, as elsewhere in the West Indies, most plants of subsp. *portoricensis* differ from mainland populations in having calyces with the teeth lanceolate to linear lanceolate, a characteristic of *Z. caracasana*. In some cases, the identification of herbarium specimens is troublesome if information concerning habit and filament color is not provided. However, there are several diagnostic characters for each taxon (Table 13, while comparing the two species, applies to the two subspecies discussed here). *Zapoteca caracasana* subsp. *caracasana* differs from *Z. portoricensis* subsp. *portoricensis* in its prostrate/scandent habit, smaller flowers, white/red-purple filaments, and by the frequent occurrence of pseudopaniculate inflorescences with more slender peduncles. The relationships between these two taxa are discussed further under *Z. caracasana*.

6b. Zapoteca portoricensis subsp. **pubicarpa** H. Hern., subsp. nov. TYPE: Mexico. Oaxaca: Dist. Huajuapan de León, a 6 km NW de San Jerónimo Silacayoapilla, casi en la desviación a Ciénega Zahuatlán, veg. alterada de *Bursera* con *Lysiloma*, 1,900 m, 4 Dec. 1978, *Sousa & Zárate 9822* (holotype, MEXU; isotype, CAS).

Pinnae 2–4-juga; foliola 15–30-juga in pinna utraque angusto-oblonga vel lanceolata. Calyx 2–3(–3.5) mm longus, dentibus villosis saepe forte villosis; corolla 7–8(–10) mm longa saepe apice villosa. Legumina puberula.

Erect shrubs, to 3 m tall; branchlets villous to densely villous with white-gray hairs. Pinnae 2–4-jugate; leaflets 15–30 pairs per pinna, narrowly oblong to lanceolate, oblique at base, acute at apex, mucronulate, the median ones 4–7 × 1–2 mm, ciliate, rarely sparsely villous; stipules narrowly triangular, to 11 mm long, usually densely villous. Capitula axillary; peduncles costate, 1.3–3.5(–6) cm long at anthesis, glabrous to densely villous. Calyx 2–3(–3.5) mm long, the teeth triangular, the area of the teeth villous to densely villous; corolla 7–8(–10) mm long, usually villous apically; ovary glabrous. Pods ca. 6–7 cm long, brown, puberulent.

Distribution (Fig. 36). Endemic to a restricted area in southern Puebla and northern Oaxaca, where it has been collected in disturbed places in the transition zone between oak and tropical deciduous forests and in thorn forests. Collections come from 1,850–2,120 m. Plants of this subspecies grow in a generally drier environment than other mainland populations of the species.

Additional specimens examined. MEXICO. PUEBLA: 259 km SE of Mexico City, *Barr et al. 62-709* (MEXU); vicinity of San Luis, Barranca de Tlacuilosto, *Purpus s.n.* (BM, F, GH, MO, NY, UC, US); Cerro de la Yerba, San Luis Tultitlanapa, Sierra Mixteca, *Purpus 2668* (G, UC); 4.4. mi. SW of Acatepec, *Schaffner et al. 74-64b* (US); a 7 km al SW de Acatepec, *Sousa 7740* (MO); Mpio. de Zapotitlán de las Salinas, a 8 km al SW de Acatepec, *Sousa & Rico 10322* (MO); El Coro, 10 km NW de Caltepec, o 6 km SE de Acatepec, *Tenorio 6859* (MEXU); Mpio. Caltepec, Rincón de la Hierba, Mesa Chica al W de Caltepec, *Tenorio & Romero 7604* (MEXU).

Zapoteca portoricensis subsp. *pubicarpa* is closely related to subsp. *portoricensis*, from which it can be distinguished primarily by having puberulent pods, villous calyx teeth, larger flowers, and usually shorter peduncles (see Table 12). The ovaries are glabrous, but pubescence becomes evident soon after the pods start to develop. The characteristics used to define this subspecies are not discontinuous with those of subsp. *portoricensis*. However, the particular combination of morphological characters defining subsp. *pubicarpa* is distinctive and appears to be relatively constant throughout its range. This and its biogeographic consistency justify its recognition as a separate subspecies.

The pubescence of the pods is the main diagnostic character for this subspecies. Nevertheless, hairy pods have been found in two collections of *Z. portoricensis* subsp. *portoricensis* from Nicaragua (*Laguna 333*, *Moreno 8272*). These plants, however, have smaller flowers and longer peduncles than are characteristic of subsp. *pubicarpa*; they clearly fall within the limits of subsp. *portoricensis*. Flower size is variable in subsp. *portoricensis*, with large (calyx = 2–3 mm long, corolla = 6–8 mm long) flowers found in plants throughout the range of this subspecies; such flowers, however, are rarely as large as those of *Z. portoricensis* subsp. *pubicarpa*, and the plants on which they occur never have the hairy pods or short peduncles characteristic of subsp. *pubicarpa*.

6c. Zapoteca portoricensis subsp. **flavida** (Urban) H. Hern., comb. et stat. nov. *Calliandra flavida* Urban, Ark. Bot. 24A: 4. 1931; Britton & Killip, Ann. New York Acad. Sci. 35: 137. 1936. TYPE: Grenada, ad Belvedere, 1,600 ft., Dec. 1889, *Eggers 6226* (lectotype, US 938738, here designated; isolectotype, GH).

Scandent shrubs, 2–3(–7) m tall; stems slender; branchlets terete, usually spreading and descending, glabrous to sparsely villous, sometimes densely villous in the younger parts. Pinnae (2–)3–5(–7)-jugate; leaflets 8–18(–36) pairs per pinna, the median ones oblong to oblong-obovate, sometimes subfalcate, oblique at base, rounded to acute at apex, mucronulate, 7–20 × 2–6 mm, finely villous on both surfaces; stipules triangular-lanceolate, occasionally linear-triangular, to 11(–13) mm long, glabrous, ciliate. Capitula commonly axillary, occasionally in pseudopanicles to 20 cm long; peduncles slender, 3–7.5 cm long at anthesis. Calyx 1–2 mm long, glabrous, the teeth triangular to deltate, rarely narrowly oblong, acute, occasionally irregular; corolla 3–4 mm long. Pods to 16.5 × 1.2 cm at maturity, thickly membranous, usually black at maturity. Seeds ovoid to very widely ovoid, ca. 6 × 4–5 mm, brown to dark brown, the areola usually mottled, pleurogram irregular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 36). *Zapoteca portoricensis* subsp. *flavida* primarily occurs in lowland tropical forests, where it is commonly found along river banks, in inundated areas, and in wet thickets. Its range extends from southeastern Veracruz and northern Oaxaca, Mexico to Venezuela and Peru, where it has been collected in several disjunct populations. Additional collections have been made in Grenada (Lesser Antilles), Guyana, in the states of Pará, Ceará, Pernambuco, Goiás, Mato Grosso, Brazil, and in the department of Santa Cruz, Bolivia. In Mexico and Central America it is primarily a lowland subspecies, extending altitudinally from 0 to 670 m elevation; in Venezuela it reaches 1,100 m. This subspecies has been introduced to Africa, where it has been collected from naturalized populations in Ghana (*Enti 275*, *Vigne 1011*) and from cultivated individuals in Nigeria (*Guile 701*).

Additional specimens examined. MEXICO. CHIAPAS: Mpio. Palenque, a 6 km W del entronque a Palenque, *H. Hernández & Torres 805* (MEXU, MO); Bonampak, *Hoover 283* (GH, MO, US); Mpio. This subspecies can be easily distinguished from subsp. *portoricensis* and *pubicarpa* by its scandent habit, larger, usually less numerous leaflets, and usually larger pods. In addition, subsp. *flavida* primarily grows in habitats associated with lowland tropical forests, whereas the two other subspecies have been collected chiefly in subtropical, mid- to relatively high-altitude habitats. *Zapoteca portoricensis* subsp. *flavida* can be distinguished from *Z. caracasana* by having larger leaflets, flower buds constantly glabrous, deltate-triangular calyx teeth, white filaments, and larger pods. The capitula are arranged in pseudopanicles only occasionally in *Z. portoricensis* subsp. *flavida*; this is a very common condition in *Z. caracasana*.

Zapoteca portoricensis subsp. *flavida* is relatively constant morphologically throughout its wide range; however, a number of collections from South America have a combination of characters that differ from those of the Mexican and Central American plants. Characteristics of a collection from Colombia (*Philipson et al. 1418*) suggest morphological intergradation between *Z. portoricensis* subsp. *flavida* and *Z. caracasana*: narrowly triangular to linear-triangular stipules, leaflets 8 × 2 mm, numerous (to 36) pairs of leaflets per pinna, capitula arranged in elongate pseudopanicles, calyx with linear-lanceolate teeth, and white filaments. An almost identical situation is displayed by most of the Brazilian collections of *Z. portoricensis* subsp. *flavida* (*Andrade-Lima 70-5777, Ducke 1517, 16051, Fróes 30295, Guedes 378, Hatschbach 34270, Pickel 2430, Tavares 754*). Here, several of the vegetative and reproductive characters diagnostic of either *Z. portoricensis* subsp. *flavida* or *Z. caracasana* intergrade in particular populations.

Although it is not known whether *Z. portoricensis* subsp. *flavida* and *Z. caracasana* ever actually grow together in specific habitats, they have been collected in comparable microhabitats (e.g., river banks, shady sites, and thickets), which raises the possibility of hybridization. Populations of *Z. caracasana*, however, occur more commonly in drier habitats than do those of *Z. portoricensis* subsp. *flavida*. The distributions of these two taxa overlap only in the area of the Andes, where there is much local microhabitat differentiation.

Collections from Bolivia have some characters that do not correspond with those commonly found in individuals of *Z. portoricensis* subsp. *flavida*. For instance, the filaments are reported to be white-pink, instead of white, in *Steinbach 822*. The calyx in almost all the Bolivian collections has lanceolate teeth (*Steinbach 5412, Weddell 4237, Williams 267*). In addition, the mature pods are always smaller than typical for this entity (to 10 cm long)

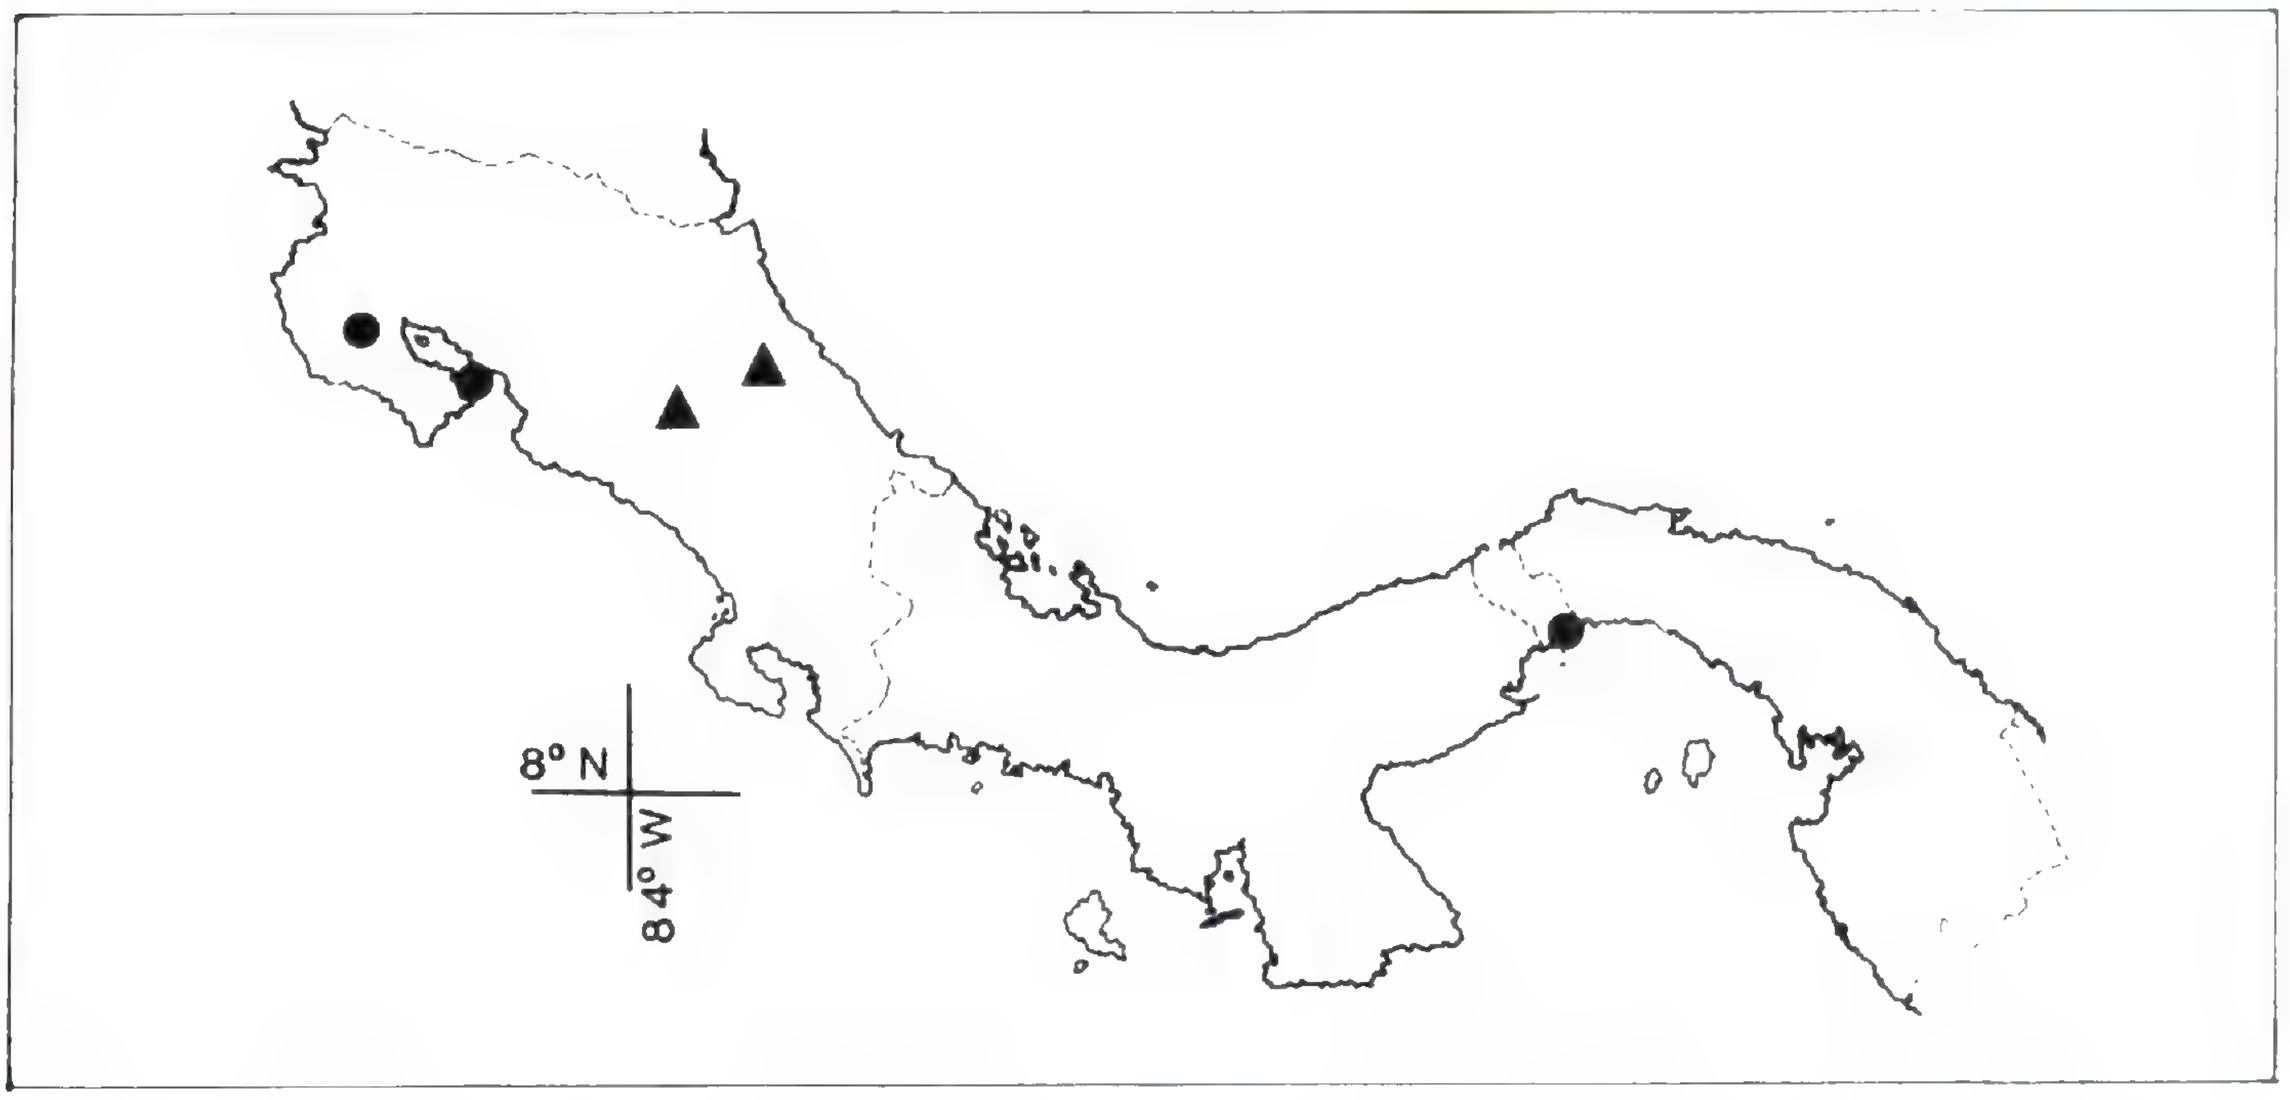

FIGURE 37. Distribution of *Zapoteca mollis* (dots) and *Z. costaricensis* (triangles), Costa Rica and Panama.

and the valves are thicker (e.g., *Pierce s.n.*, *Troll 1738*, *Williams 241*).

7. **Zapoteca mollis** (Standley) H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. *Calliandra mollis* Standley, Contr. U.S. Natl. Herb. 17: 431. 1914; Standley, Publ. Field Mus. Nat. Hist., Bot. Ser. 18: 492. 1937. *Anneslia mollis* (Standley) Britton & Rose, N. Amer. Fl. 23: 65. 1928. TYPE: Costa Rica: buissons à Nicoya, Jan. 1900, *Tonduz 13536* (holotype, US no. 578114; isotypes, BM (2), F, G (3), GH, K (2), LE, NY (3), US (2)).

Erect shrubs to 3 m tall; branchlets terete, costate under magnification, abundantly villous with tawny hairs. Pinnae (3–)4–6-jugate; petioles eglandular, terete, with a conspicuous channel in the adaxial surface, 1.2–4.5 cm long, abundantly villous; rachis 3.5–9.5 cm long, abundantly villous; rachillae 4.5–12.5 cm long in well-developed leaves; leaflets 15–26 pairs per pinna, narrowly oblong, oblique at base, acute to rounded and mucronulate at apex, the median leaflets 7–18 × 2–5 mm, the proximal ones smaller, all membranous, drying a light green in the abaxial surface, densely pilose with white hairs on both surfaces; leaflet venation inconspicuous; stipules leafy, triangular-lanceolate, acute, ca. 6–14 mm long, parallel-veined, pilose, ciliate. Capitula in simple, rarely compound, pseudopanicles 3.5–15 cm long; peduncles usually fasciculate, rarely solitary, 2.5–4 cm long at anthesis, usually densely villous with tawny hairs. Calyx ca. 2–3 mm long, glabrous, the teeth lanceolate, acute, ca. 2 mm long; corolla infundibuliform, ca. 3–4 mm long, glabrous, the lobes ovate-lanceolate, acute; filaments about 2.5 cm long, the basal half white and the distal half ochroleucous, the staminal tube ca. 2 mm long; ovary ca. 2–3 mm long when fertile, glabrous, sometimes with fine translucent hairs, sessile. Pods to 9 × 0.7 cm when mature, with the apex rounded, rarely truncate, rostellate, thickly membranous, densely villous with long tawny hairs. Seeds widely rhomboid, flattened, ca. 4 × 3 mm, dark colored, the areola lighter, pleurogram irregular.

Distribution (Fig. 37). This species has been collected in tropical dry forests near Nicoya (Peninsula of Nicoya), in San Lucas Island (Gulf of Nicoya), and in Río Lagarto, all in Prov. Puntarenas, Costa Rica. Plants from a presumably disjunct population have been collected in Santa Cruz, near Panama City, Panama.

Additional specimens examined. COSTA RICA. PUNTARENAS: Island of San Lucas, Gulf of Nicoya, *Barclay 2756* (BM, MO, US); Isla de San Lucas, Golfo de Nicoya, along Quebrada Hacienda Vieja, 9°57′N, 84°54′W, *Grayum et al. 4164* (MEXU, MO); Isla de San Lucas, Golfo de Nicoya, between Playa Tumbabote and Punta Barrigona, *Grayum 4201* (MEXU, MO); Isla de San Lucas, Golfo de Nicoya, along trail to Punta Cirial, *Grayum 4290* (MEXU, MO); Río Lagarto, entronque a Monteverde y Guacimal, *Téllez 4307* (MEXU). PANAMA: Santa Cruz, *Arroyo 37* (MO).

This species closely resembles *Z. portoricensis* subsp. *flavida* in general characteristics of leaves and inflorescences, but it can be distinguished readily by having an erect habit, which contrasts with the scandent habit of the subspecies, and by being villous or pilose throughout, including the pods,

which are densely covered with long tawny hairs. Further, the filaments are white in *Z. portoricensis* subsp. *flavida*, but white in the basal half and ochroleucous in the distal half in *Z. mollis* (*Grayum 1162, 4290*). (It would be desirable to check more living individuals for this feature.) Contrasted with *Z. portoricensis* subsp. *flavida*, which is commonly found in thickets in wet lowland habitats (e.g., along water courses and near ponds), populations of *Z. mollis* usually occur in relatively dry habitats. With the exceptions of *Z. formosa* subsp. *salvadorensis*, *Z. caracasana* subsp. *weberbaueri*, and *Z. portoricensis* subsp. *pubicarpa*, this is the only species in the genus with hairy pods.

In addition to the few collections of this species from Costa Rica, there is a collection from Santa Cruz, near Panama City (*Arroyo 37*), which indicates a disjunction in its range. This collection, with immature pods, matches the plants collected in Costa Rica well. Recent attempts (1984) to recollect from this population have been unsuccessful, presumably due to widespread destruction of natural habitats in this part of Panama.

8. Zapoteca caracasana (Jacq.) H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. *Mimosa caracasana* Jacq., Collectanea 4: 142. 1791. *Acacia caracasana* (Jacq.) Willd., Spec. 4: 1068. 1806; DC., Prodr. 2: 467. 1825; G. Don, Gen. Hist. 2: 419. 1832. *Calliandra caracasana* (Jacq.) Benth., London J. Bot. 3: 99. 1844; Benth., Trans. Linn. Soc. London 30: 543. 1875; Britton & Killip, Ann. New York Acad. Sci. 35: 137. 1936; J. F. Macbr., Fieldiana, Bot. 13: 69. 1943; Woodson & Schery, Ann. Missouri Bot. Gard. 37: 260. 1950; L. Cárdenas, Revista Fac. Agron. (Maracay) 7: 131. 1974. *Feuilleea caracasana* (Jacq.) Kuntze, Revis. Gen. Pl. 184. 1891. *Anneslia caracasana* (Jacq.) Britton & Rose, N. Amer. Fl. 23: 65. 1928. TYPE: Jacq., Icon. Pl. Rar. 3: 20, t. 632. 1793 (neotype here designated, copies at MO, NY, U). I have designated this excellent illustration as neotype (Fig. 38) because no other element on which the description of *Mimosa caracasana* was based appears to have survived.

Scandent, subprostrate or prostrate shrubs; stems usually branching shortly above soil level, ca. 2 cm diam.; branchlets flexible, elongate, usually to 3(–5) m long, terete, sometimes angulate, costate, glabrous to densely villous. Pinnae (1–)2–7-jugate; leaf primordia usually densely villous or pilose; petioles eglandular, terete, with a conspicuous channel adaxially, 0.9–5 cm long, usually villous or pilose; rachis (0.4–)1–7.5 cm long; rachillae 2–6(–7.5) cm long; leaflets 10–26(–37) pairs per pinna, narrowly oblong, oblique at base, rounded to acute at apex, the median ones (4–)5–10(–11) × (1–)1.5–2.5(–3) mm, the proximal ones smaller, all membranous, glabrous to short-villous, usually ciliate; leaflet venation usually conspicuous abaxially, the primary and secondary veins prominent; stipules leafy, narrowly triangular to linear-triangular, sometimes subauriculate at base, acuminate, parallel veined, to 7(–12) mm long, glabrous to villous, usually ciliate. Capitula axillary or in simple or, less frequently, compound pseudopanicles to 20(–26) cm long; peduncles fasciculate at distant nodes, 1.5–6.5 cm long at anthesis. Flowers pentamerous, sometimes hexamerous; calyx cup-shaped, deeply divided to the base, 1.5–2 mm long, glabrous to densely covered with relatively long wavy hairs in bud, glabrous, villous or ciliate at anthesis, the teeth lanceolate to linear-lanceolate; corolla campanulate, 3–4 mm long, glabrous, the lobes lanceolate; filaments ca. 2.5 cm long, white in the basal half, purple-red in the distal half, the staminal tube ca. 1.5 mm long; ovary ca. 1 mm long when fertile, glabrous or occasionally with a few hyaline hairs, shortly stipitate. Pods straight, sometimes slightly curved, apex usually curvedly rostrate, 10(–11) × 0.7(–0.8) cm, thickly membranous, glabrous, glabrate, or canescent, becoming densely short-pubescent. Seeds ovoid to rhomboid-ovoid, 4–6 × 3–4 mm, mottled or brown; pleurogram irregular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 39). Populations of this species occur primarily in disturbed habitats derived from a wide variety of vegetation types, ranging from dry scrubby vegetation to wet evergreen forests. Its range extends from northern Venezuela (including Isla Margarita) southwest to Colombia, Ecuador, and Peru, where it has been collected in scattered localities. It has also been found in Hispaniola and in a distant disjunct population in Honduras. Perhaps this is the species within *Zapoteca*

→

FIGURE 38. "*Mimosa caracasana*" (= *Zapoteca caracasana* subsp. *caracasana*), from Jacquin's *Icon. Pl. Rar.* 3: 20, t. 632. 1793.

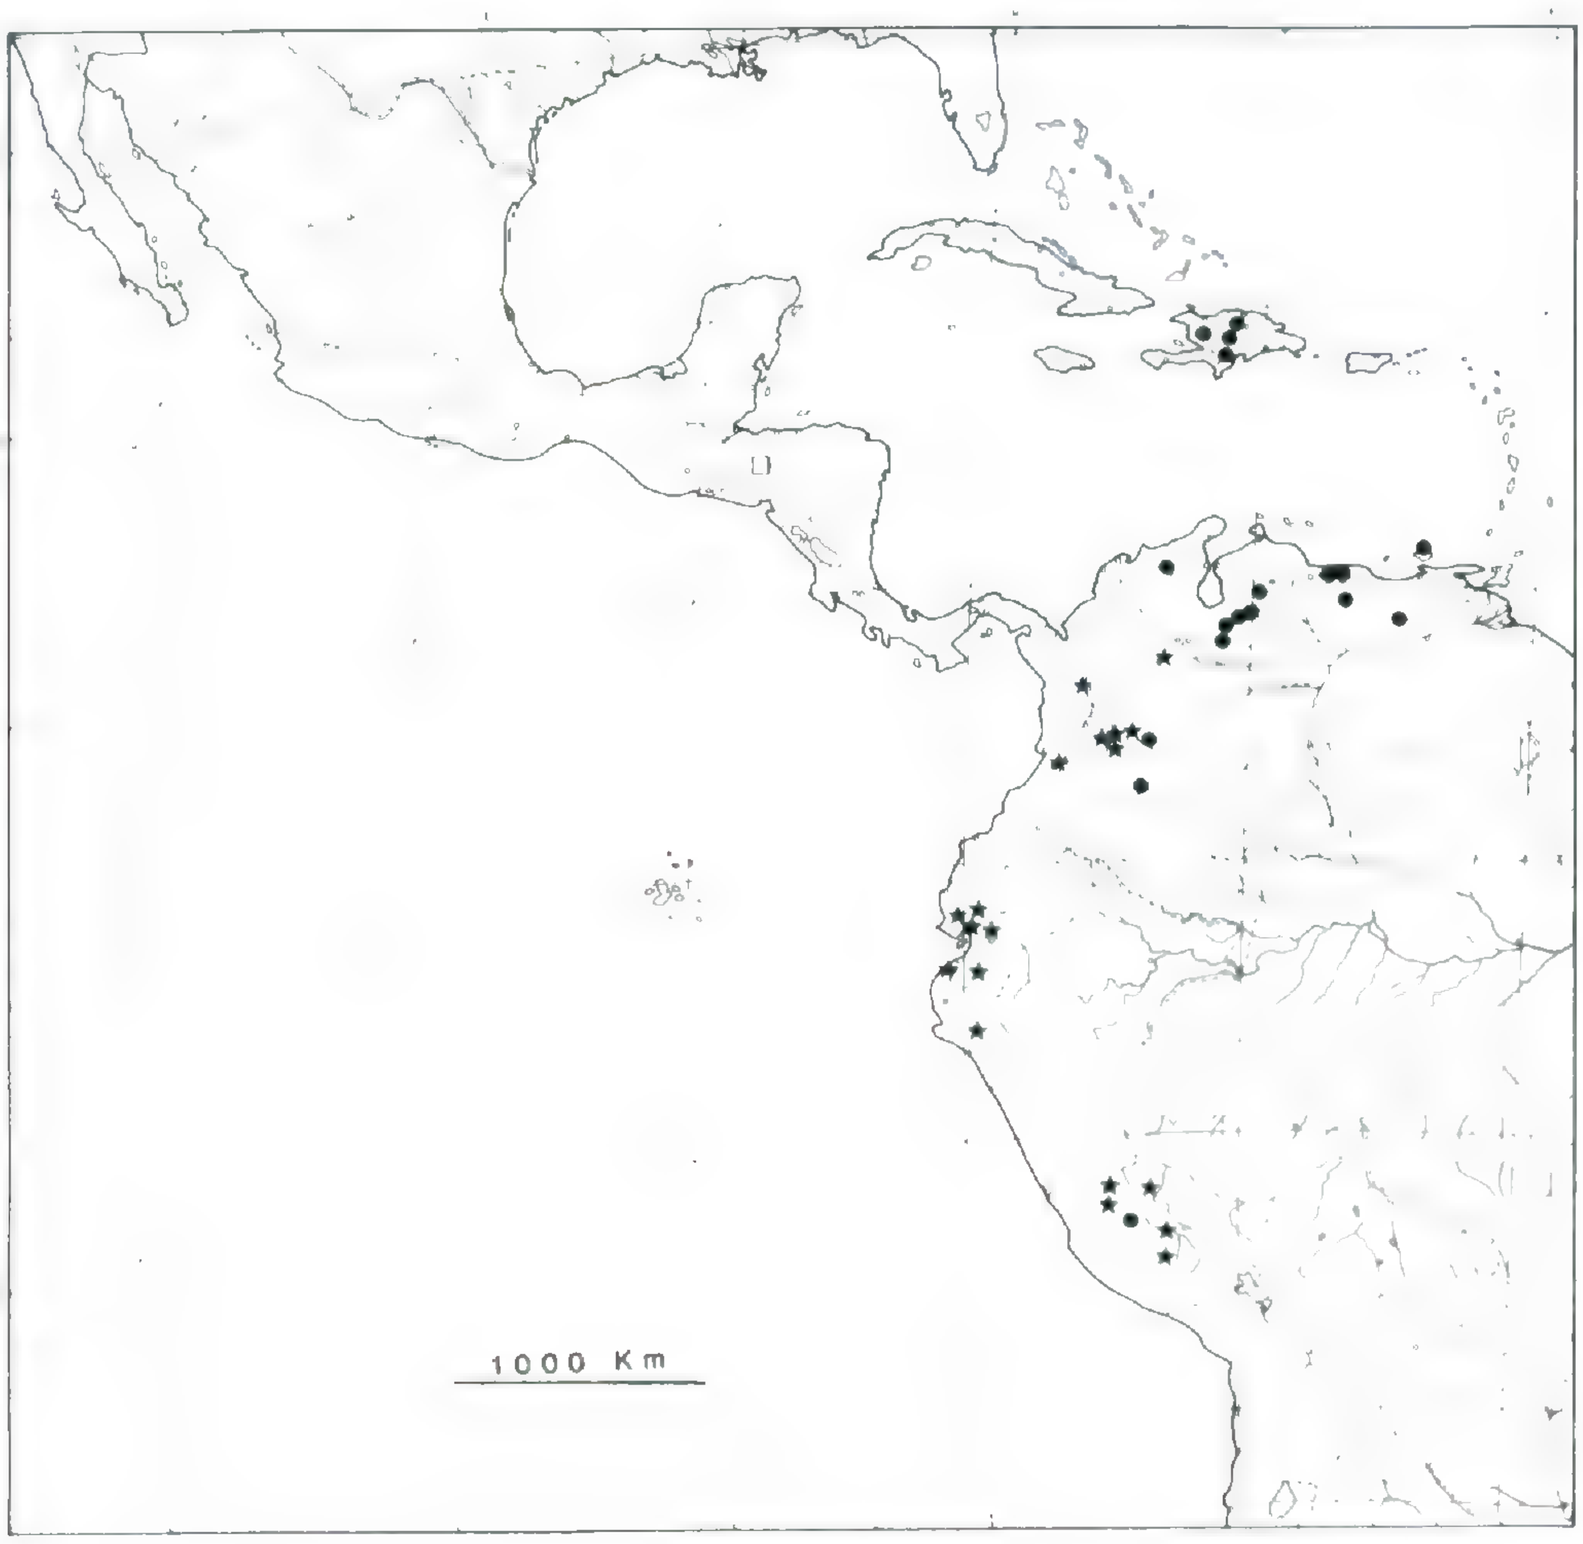

FIGURE 39. Distribution of *Zapoteca caracasana* subsp. *caracasana* (dots), *Z. caracasana* subsp. *weberbaueri* (stars), and *Z. caracasana* of unknown subspecific affinity (open square).

of which populations occupy the widest altitudinal range: 0–2,500 m. Woodson & Schery (1950) incorrectly included this species in the *Flora of Panama*.

Zapoteca caracasana is closely related to *Z. portoricensis*, and these two species have been merged at times. For instance, Bentham (1844) considered *Z.* (*Calliandra*) *caracasana* as a synonym of *C. portoricensis*, although subsequently, in his revision of Mimosoideae (Bentham, 1875), he recognized them as distinct species. Later, Woodson & Schery (1950) treated *Calliandra portoricensis* as a synonym of *C. caracasana*. The most important characters distinguishing these two species are outlined in Table 13. Although identification of herbarium specimens is admittedly difficult in some cases, *Z. caracasana* can be distinguished from *Z. portoricensis* by its presumably constant scandent or prostrate habit, usually smaller leaflets, and capitula with more slender peduncles, which are usually arranged in pseudopaniculate inflorescences, a condition rarely found in *Z. portoricensis*. Observations on cultivated material and information from herbarium specimens suggest that the scandent/prostrate habit of *Z. caracasana* is widespread throughout its range; however, it is uncertain whether it is characteristic of all the populations or if erect plants occasionally occur, as indicated by label information on a few specimens. Within *Z. portoricensis*, the scandent habit occurs only in subsp. *flavida*. There are, however, important differences in growth habit between that entity and *Z. caracasana*: cultivated specimens of of *Z. caracasana* (*H. Hernández 961*) had extremely short primary stems, usually giving rise to drooping, very elongate branchlets ca. 10 cm above the soil level, while those of *Z. portoricensis* subsp. *flavida* develop very long, flexible primary stems, sometimes reaching several meters before giving rise to secondary branches.

The flowers of *Z. caracasana* are generally smaller than those of *Z. portoricensis*, and the calyces are consistently deeply divided to the base, with the teeth lanceolate to linear-lanceolate. In addition, the two species are easily distinguished by their filament colors (Table 13) and by the usually smaller pods in *Z. caracasana*. Pod size, however, is highly variable in *Z. portoricensis*.

Although the degree of pubescence of stems and leaves is extremely variable in *Z. caracasana* and in *Z. portoricensis*, the branchlets of the former

TABLE 13. Comparison of *Zapoteca caracasana* with *Z. portoricensis*.

	Z. caracasana	*Z. portoricensis*
Habit	scandent, prostrate	scandent, erect
Leaflet l × w	4–11 × 1–3 mm	4–20 × 1–6 mm
Capitula	commonly arranged in pseudopanicles, or axillary	usually axillary, rarely in pseudopanicles
Calyx	deeply divided with the teeth lanceolate to linear-lanceolate	teeth triangular or deltate, rarely lanceolate to linear-lanceolate
Corolla length	3–4 mm	3–8(–10) mm
Filament color	white–red-purple	white
Maximum pod length	to 11 cm	to 16.5 cm

are never as densely villous as commonly in the latter. Similarly, the indumentum of the calyx is highly variable in *Z. caracasana*, most of the collections with completely glabrous calyces being concentrated in Ecuador. However, the peculiar vestiture observed in the flower buds of this species has never been observed in *Z. portoricensis*. Further discussion of the relationships between these two species is under *Z. portoriensis*.

Zapoteca caracasana consists of two closely related subspecies: *caracasana* (with glabrous pods) and *weberbaueri* (with canescent or pubescent pods). As in the other taxa of *Zapoteca* with pubescent pods (*Z. mollis*, *Z. portoricensis* subsp. *pubicarpa*, *Z. formosa* subsp. *salvadorensis*), the ovaries of *Z. caracasana* subsp. *weberbaueri* are glabrous, and the hairs of the pods presumably develop after fertilization. However, the ovaries in this subspecies occasionally have a few hairs.

KEY TO THE SUBSPECIES OF *ZAPOTECA CARACASANA*

1a. Pods glabrous or nearly so ..... 8a. subsp. *caracasana*

1b. Pods canescent or pubescent ..... 8b. subsp. *weberbaueri*

8a. Zapoteca caracasana (Jacq.) H. Hern. subsp. **caracasana.**

Branchlets villous to glabrate, usually glabrate, rarely densely villous. Calyx densely covered with usually wavy, long hairs or glabrous in bud, the teeth usually ciliate at anthesis; ovary glabrous. Mature pods to 10(–11) × 0.7(–0.8) cm, glabrous, rarely glabrate. Seeds 5–6 × 4 mm.

Distribution (Fig. 39). Relatively common along roadsides, in cultivated fields and thickets, and in shady sites. In the West Indies it occurs on Hispaniola. On the mainland, it has been collected in northern Venezuela (including Isla Margarita), in a few presumably disjunct localities in the departments of Magdalena and Meta, Colombia, and the Department of Ayacucho, Peru. *Zapoteca caracasana* subsp. *caracasana* appears to be allopatric with *Z. caracasana* subsp. *weberbaueri*, although their ranges come into proximity in Colombia and Peru. Collections come from altitudes of 200–1,300(–2,500) m. This subspecies has also been collected from cultivated individuals at the Botanical Garden of Pará, Brazil (*Huber 2078*). Given the fact that the only collection from Honduras lacks pods, it is not possible to assign it to a subspecies.

Common name. Cujicillo (Dominican Republic).

Additional specimens examined. HAITI: Massif des Cahos, Les Gonaives, *Ekman 9081* (GH, K, MO, NY, S, US). DOMINICAN REPUBLIC. HONDURAS: COPÁN(?): Quebrada N of Copán, *Poole & Watson 1034* (LL).

8b. Zapoteca caracasana subsp. **weberbaueri** (Harms) H. Hern., comb. et stat. nov.

Calliandra weberbaueri Harms, Repert. Spec. Nov. Regni Veg. 17: 88. 1921. TYPE: Peru. Huancavélica: Prov. Tayacaja, Valley of the Mantaro, northeast of Pampas, 1,600 m, Mar. 1913, *Weberbauer 6511* (lectotype, GH, here designated; isolectotypes, F, G (fragm.), S, US).

Branchlets densely villous to usually glabrate. Calyx very densely covered with usually wavy, long hairs, or glabrous in bud, the teeth ciliate or glabrous at anthesis; ovary glabrous, very rarely with a few, translucent hairs. Mature pods to 10 × 0.7 cm, usually canescent when young, densely short-pubescent at maturity. Seeds 4–5 × 3–3.5 mm. Somatic chromosome number $2n = 26$.

Distribution (Fig. 39). This subspecies occurs primarily in relatively dry, scrubby vegetation. It has been collected from scattered localities in Colombia, in the departments of Antioquia, Cauca, Cundinamarca, Santander, Tolima, and Valle; in Ecuador, in the provinces of Chimborazo, Guayas and Loja; and in Peru, in the departments of Apurímac, Cuzco, Huancavélica, Lambayeque, and Tumbes. Collections come from elevations of 0 2,500 m.

Additional specimens examined. COLOMBIA. ANTIOQUIA: vicinity of Medellín, *Toro 787* (NY, US). CUNDINAMARCA: alrededores de Puente de San Antonio de Tena, *Cuatrecasas 8284* (F, US); La Esperanza, *García 4675* (US); Santandercito, *Uribe 467* (US). LAMBAYEQUE: km 28 E of Olmos, between Olmos and Jaen, *Hutchison & Wright 3411* (NY, UC). TUMBES: between Quebrada Seca y Matapalo, *Ferreyra et al. 10685* (MO, US).

This epithet has traditionally been associated with *Z. portoricensis* (Macbride, 1943), perhaps because of the superficial similarities between this species and *Z. caracasana*. The type material of "*Calliandra weberbaueri*," however, has a number of features suggesting its inclusion within *Z. caracasana*. For instance, the calyx is deeply divided, and the filaments are "white/pinkish-red" as indicated in Weberbauer's collection. In addition, the "prominent" leaflet veins in the type collection, as seen under magnification, are like those observed in many other collections of *Z. caracasana*.

Acacia fragrans Ten. nom. nud., Cat. Ort. Nap. 1 was apparently never described. There is, however, one specimen at K, clearly identified as *Z. caracasana* subsp. *weberbaueri*, which was presumably collected by Michele Tenore in the Orto Botanico di Napoli; its original source is unknown.

9. Zapoteca tetragona (Willd.) H. Hern., Ann. Missouri Bot. Gard. 73: 755–763. 1986. *Acacia tetragona* Willd., Sp. Pl. 4(2): 1069. 1806. *Calliandra tetragona* (Willd.) Benth., J. Bot. (Hooker) 2: 139. 1840; Benth., London J. Bot. 3: 99. 1844; Benth., London J. Bot. 5: 102. 1846; Benth., Trans. Linn. Soc. London 30: 543. 1875; S. Watson, Proc. Amer. Acad. FIGURE 40. Distribution of *Zapoteca tetragona*.

Ann. New York Acad. Sci. 35: 137. 1936. TYPE: Colombia. Antioquia: vicinity of Medellín, 18 Aug. 1927, *Toro 465* (holotype, NY, photo, G).

Mostly shrubs to 5 m tall, rarely trees to 12 m tall; stems 2–4(–20?) cm diam.; branchlets conspicuously 4-angled, sometimes herbaceous in the younger parts, with the surface costate under magnification, mostly densely villous with tawny hairs when young, becoming glabrate. Pinnae (3–)4–7-jugate; petioles eglandular, with a conspicuous adaxial channel, angled, 1.7–6 cm long, glabrous to densely villous; rachis (1.5)3 9(–11.5) cm long, glabrous to densely villous; rachillae (3.5–)4.5–10(–13) cm long; leaflets 10–35 pairs per pinna, narrowly oblong, oblique at base, rounded to acute at apex, the median leaflets (5–)8–18 × 1 4 mm, the proximal smaller, all membranous, glabrous or ciliate marginally, always glabrous on both surfaces; leaflet venation inconspicuous; stipules leafy, adpressed, triangular-linear to triangular-lanceolate, acute at apex, straight or curved, parallel-veined, (0.5–)0.8–2.5 cm long, ciliate, villous or glabrous. Capitula axillary, rarely arranged in pseudopanicles 6–22 cm long; peduncles fasciculate, (2.5–)5–12 cm long at anthesis. Calyx 2–3 mm long, the teeth deltate, ciliate; corolla funnelform, (5–)8 mm long, glabrous, the lobes lanceolate, sometimes with tufts of hairs apically; filaments usually ca. 40 mm long, white, the staminal tube ca. 3 4 mm long; ovary 2 2.5 mm long, glabrous, shortly stipitate. Pods to 16.5 × 1.4 cm, at apex truncate to obtuse, rostellate, thickly membranous, glabrous. Seeds usually ovoid, 5 6 × 3 5 mm, mostly black or dark brown; pleurogram regular, obscure. Somatic chromosome number $2n = 26$.

Distribution (Fig. 40). This widespread species has been collected primarily in moist thickets, along streams or river banks, and, in general, in ruderal habitats derived from tropical and subtropical evergreen forests. Its range extends from Mexico (Nayarit and northern Veracruz) southeast through Central America along the Andean Cordillera in which it reaches southern Ecuador. Populations develop primarily at moderate and less frequently at low altitudes (0–1,500 m), although in some parts of Central and South America they can reach altitudes of 2,300 m.

Common names. Angel (Veracruz), atzalaquio (Puebla), barba de chivo (Veracruz), cabellito blanco (Oaxaca), cabellito de angel (Michoacán, Guerrero, Puebla), cabeza de viejo (Oaxaca, Veracruz), carbonero blanco (Colombia), carboncillo (Costa Rica), carboncillo de flor blanca (Costa Rica), cola de iguana (Jalisco), guaje silvestre (Oaxaca), guajillo (Jalisco), guajillo blanco (Oaxaca), lig tióu (Oaxaca), palo costillo (Guerrero), pelo de angel (Puebla), potosina (Jalisco), quebracho de montaña (Honduras), saqi c'alib (Quecchí name, Guatemala).

Zapoteca tetragona is closely allied to *Z. portoricensis* but can be readily distinguished primarily by having conspicuously tetragonal branchlets, larger corollas, and longer filaments. Despite the opinion of Woodson & Schery (1950), who suggested that *Z. tetragona* (*Calliandra tetragona*) is distinguished "unnaturally" by its tetragonal branchlets, implying that it is not differentiated from what they call the "*caracasana portoricensis* complex," this entity is maintained here as a separate species. Discussion of the relationship between *Z. tetragona* and *Z. portoricensis* is provided under the latter species.

Zapoteca tetragona is probably also related to *Z. andina*, from which it can readily be distinguished by having adpressed, usually larger, triangular-linear to triangular-lanceolate stipules, deltate calyx teeth, and totally white filaments. Discussion of the relationship between these two species is provided under *Z. andina*.

Acacia quadrangularis Link (Enum. Hort. Berol. Alt. 2: 445. 1822.) has traditionally been included in the list of synonyms of *Calliandra tetragona*, but I have been unable to confirm this synonymy. Link did not cite Willdenow's *Acacia tetragona*, nor Poiret's *Mimosa quadrangularis*, and given the fact that almost all of Link's personal herbarium was destroyed during World War II, there is no material available with which to evaluate this hypothesis.

10. Zapoteca andina H. Hern., sp. nov. TYPE: Ecuador. Azuay: valley of the Río Tarqui, a few km south of Cuenca, 2,500 m, 1–2 Feb. 1945, *M. A. Guiler 47* (holotype, US no. 2106703; isotype, NY). Figure 41.

Frutices ramulis praesertim juvenilibus conspicue tetragonis. Pinnae 3–6-jugae; foliolis 15–32-jugis in pinna utraque, angusto-oblongis; stipulae vadoso-triangulares basi auriculis duabus descendentibus vel depressis praeditae. Calyx ca. 2 mm longus, dentibus angusto-oblongis; filamenta basi alba ad apicem purpurea.

Shrubs to 2 m tall; branchlets conspicuously 4-angled, especially the younger ones, costate under magnification, glabrous to sparsely villous. Pinnae 3–6-jugate; petioles eglandular, with a conspicuous adaxial channel, 1.3–4 cm long, glabrous to villous; rachis 2–4 cm long; rachillae to 8 cm long; leaflets 15–32 pairs per pinna, narrowly oblong, oblique at base, acute at apex, the median leaflets 5–10 × 1–3 mm, all membranous, glabrous or ciliate; leaflet venation inconspicuous; stipules leafy, shallowly triangular, with 2 basal auricles, descending or depressed, parallel-veined, to 0.6 cm long, glabrous or ciliate. Capitula axillary; peduncles fasciculate, 3.5–7 cm long at anthesis. Calyx ca. 2 mm long, the teeth narrowly oblong, acute; corolla funnelform, ca. 4.5 mm long, glabrous, the lobes lanceolate; filaments white in the basal half, red-purple in the distal half, the staminal tube ca. 2 mm long; ovary glabrous. Pods ca. 7 × 1 cm, acute at apex, rostellate, thickly membranous, glabrous, reticulate-veined. Seeds ovoid, ca. 5 × 3 mm, mottled; pleurogram irregular.

Distribution (Fig. 42). *Zapoteca andina* is endemic to restricted areas of the Andes, in the provinces of Azuay and Loja, Ecuador; the departments of Cajamarca, La Libertad, and Piura in northern Peru; and the department of La Paz, Bolivia. This species is allopatric with *Z. tetragona*; taken together, the two species occupy a nearly continuous area of the northern Andes (Figs. 40, 42); 1,400–2,650 m.

Additional specimens examined. ECUADOR. LOJA: Hac. Huaico-Pamba, 55 km S de Loja, *Espinosa 2329* (MICH). PERU. CONTUMAZÁ: Depto. Cajamarca, La Montaña (Guzmango-Contumazá), *Sagástegui et al. 9301* (MO); Yetón-Guzmango, *Sagástegui 10321* (MO); Depto. Cajamarca, Quebrada Honda (Santiago-Yumal), *Sagástegui & López 10627* (MO). LA LIBERTAD: Prov. Otuzco, Huaranchal, *López et al. 2648* (US). PIURA: Prov. Canchaque, *Ferreyra 3133* (MO); entre Palambla y Faique, cerca a Canchaque, *Ferreyra 10920* (US). BOLIVIA. LA PAZ: Sorata, *Holway & Holway 520* (GH, US); Sorata, prope Espada, *Mandon 759* (BM, BR, GH, K, NY); without locality, *Bang 1812* (BM, F, GH, MO, NY, US).

Zapoteca andina resembles *Z. tetragona* in most of its vegetative features, although the branchlets are sometimes visibly four-angled only in the youngest parts. It differs from *Z. tetragona* primarily by having smaller, triangular, descending or depressed, auriculate stipules and by having narrowly oblong calyx teeth, smaller floral dimensions, and white/red-purple filaments. Available collections of *Z. andina* do not reveal the habit, and it is uncertain whether plants of *Z. andina* are erect shrubs or low, subprostrate or prostrate shrubs, as suggested by the aspect of some of the Bolivian collections (e.g., *Bang 1812, Mandon 759*).

11. Zapoteca costaricensis (Britton & Rose) H. Hern., comb. nov. *Anneslia costaricensis* Britton & Rose, N. Amer. Fl. 23: 67. 1928. *Calliandra costaricensis* (Britton & Rose) Standley, Publ. Field Mus. Nat. Hist., Bot. Ser. 18: 492. 1937. TYPE: Costa Rica: bords du Río Convento, Jan. 1897, *Pittier 10643* (lectotype, US no. 577350 here designated; isolectotypes, BR (2), US (2)).

Shrubs; branchlets slender, terete, smooth, glabrous. Pinnae (2–)3-jugate; petioles very slender, terete to tetragonal, with a conspicuous adaxial channel, 4.3–7 cm long, glabrous; rachis 2–2.5 cm long in 2-jugate leaves, 4.3–6.2 cm long in 3-jugate ones, glabrous or glabrate; rachillae 7–13 cm long; leaflets 10–13 pairs per pinna, the median ones narrowly oblong, the distal ones oblong-obovate, oblique at base, acute at apex, 2–2.7 × 0.5–0.7 cm, the proximal pairs smaller and narrower, all olive-green adaxially, pale-green abaxially, membranous, glabrous; leaflet venation inconspicuous; stipules leafy, ovate to widely ovate, rounded to cordate at base, acute at apex, to 13 × 8 mm, glabrous, palmately veined. Capitula axillary; peduncles 4.5–6.5 cm long in fruit. Pods to ca. 15 cm long when mature, acute, rostrate, thickly membranous, glabrous. Seeds ovoid, 7 × 4 mm, brown; pleurogram irregular.

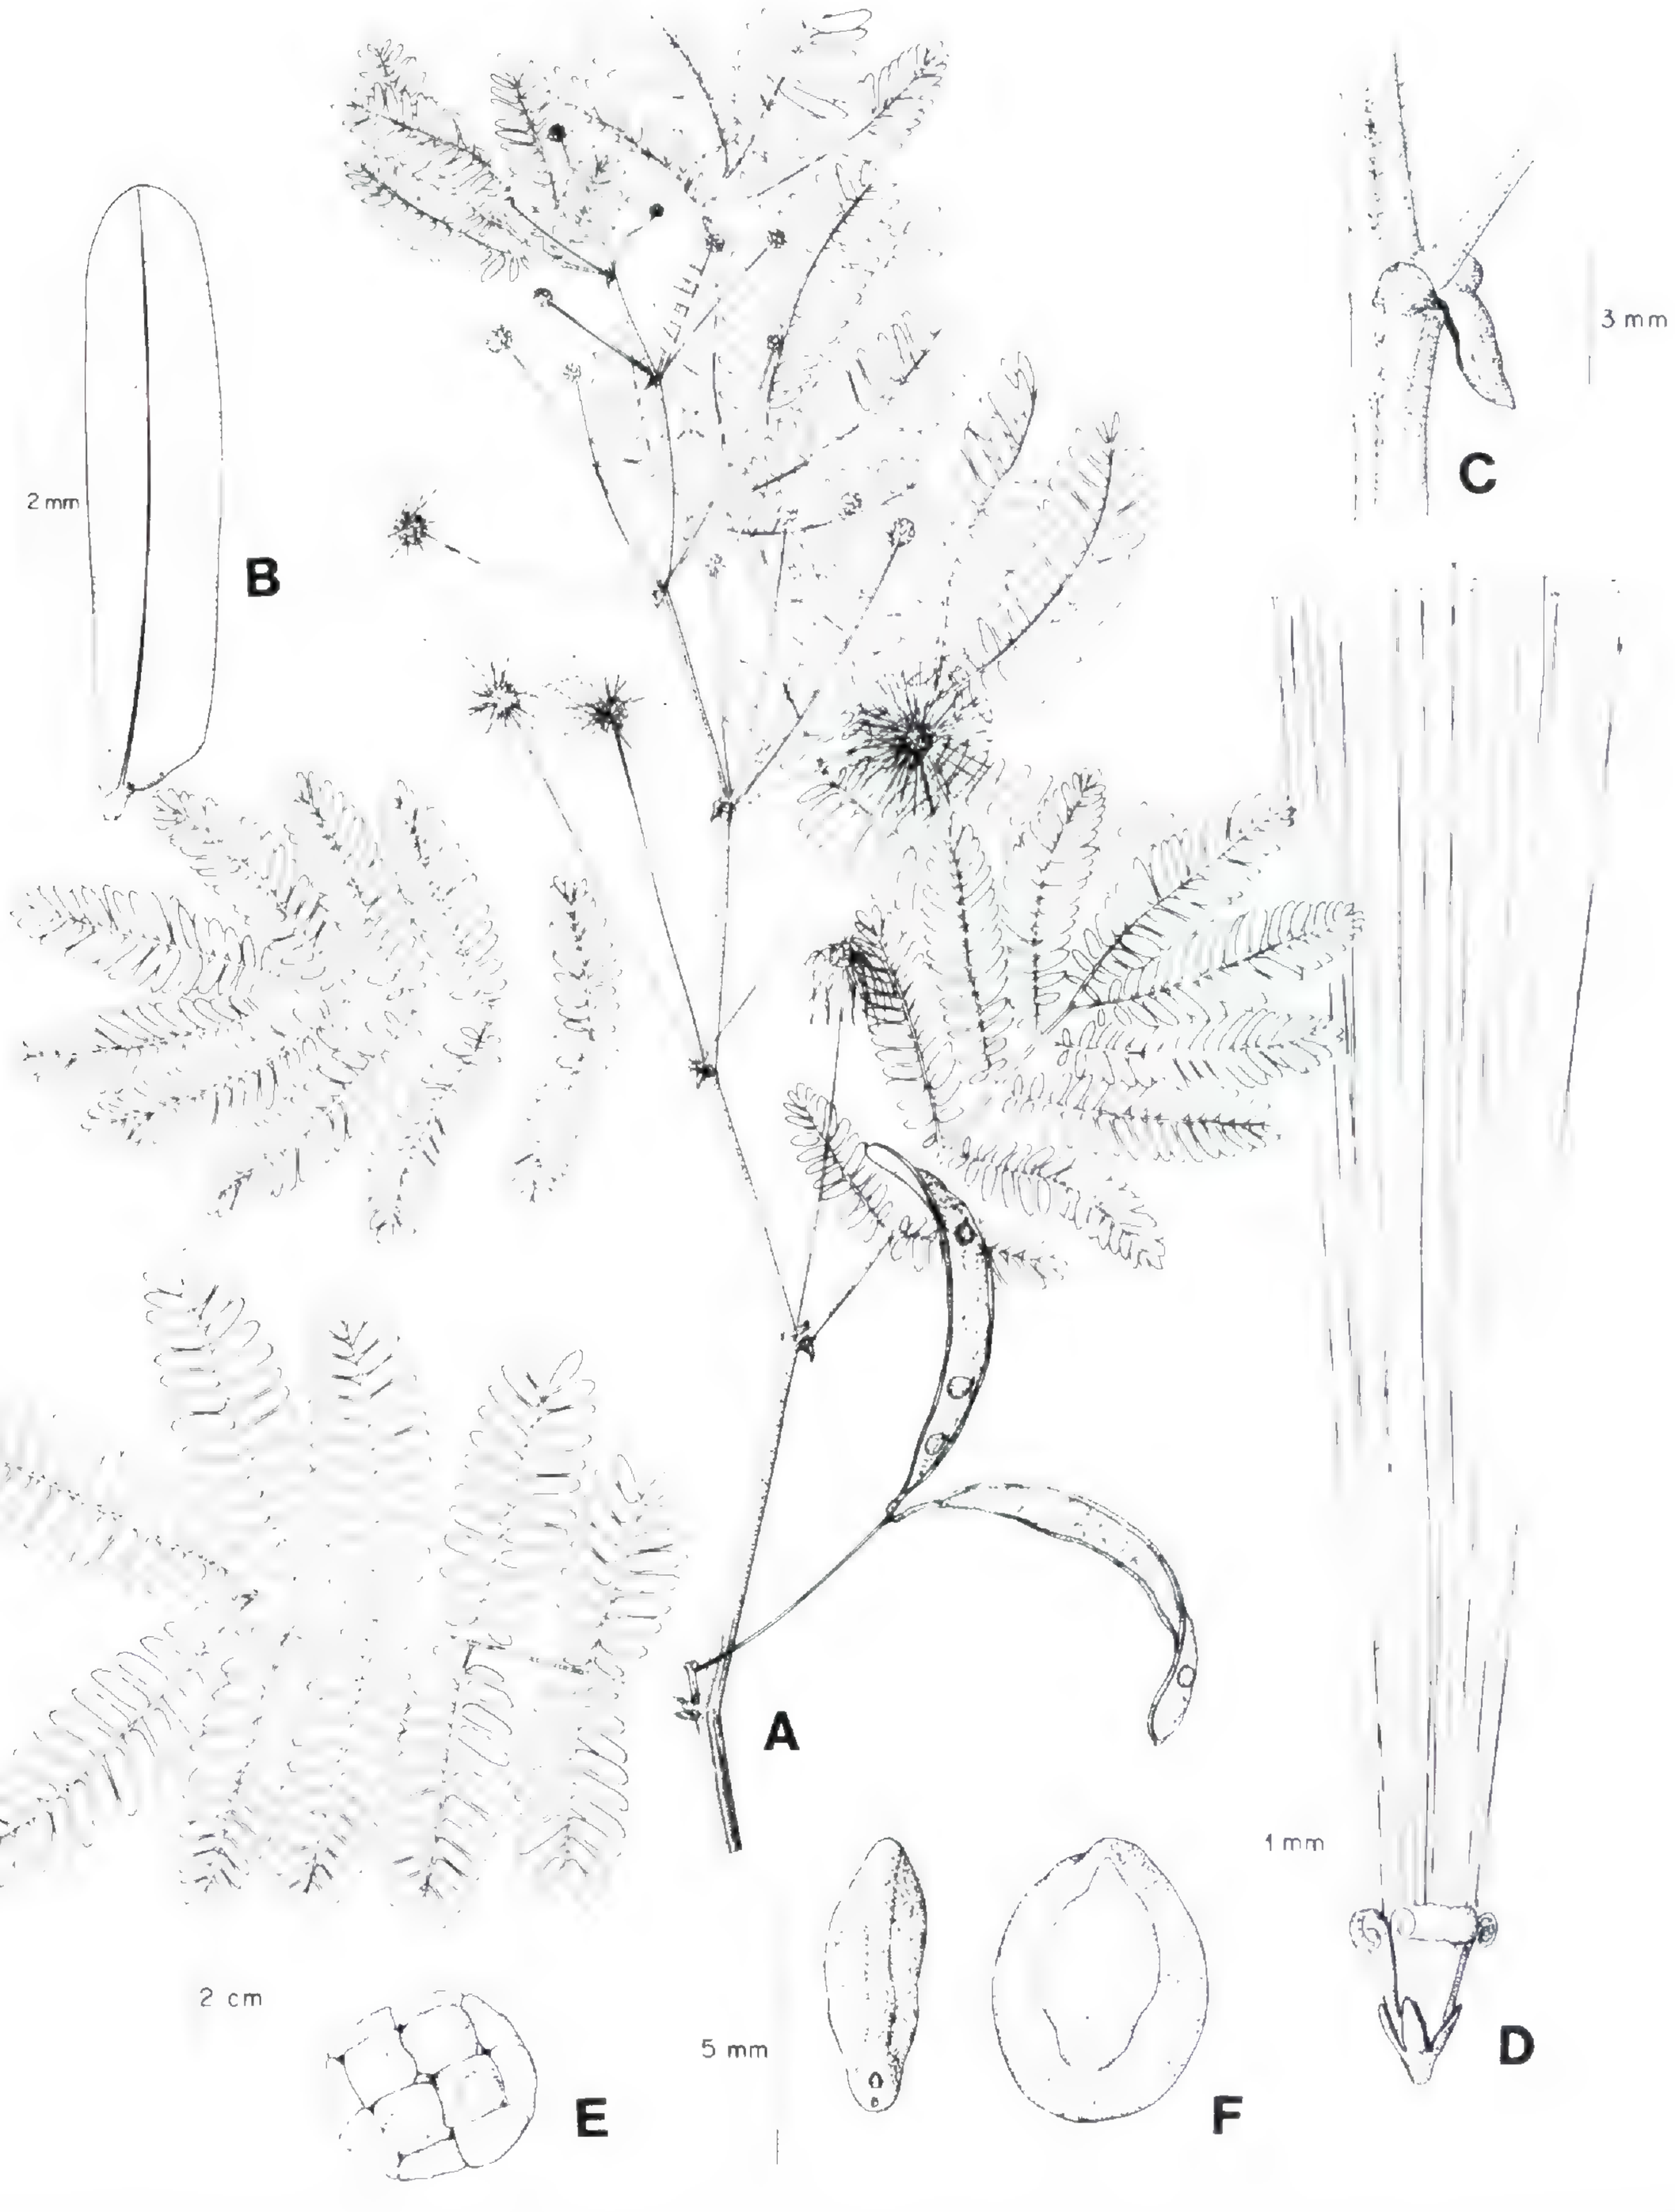

FIGURE 41. *Zapoteca andina.*—A. Branchlet with inflorescences at anthesis, and dehisced pod.—B. Leaflet. C. Stipule.—D. Flower.—E. Polyad.—F. Seeds. (From *Espinosa 2329* (MICH); pod from *Sagástegui et al. 10321* (MO).)

Distribution (Fig. 37) *Zapoteca costaricensis* is endemic to Costa Rica, where it is known from only two collections, one from Valle del Río Diquís (Río Convento) near San José and the other from near Siquirres, Province of Limón.

Additional specimen examined. COSTA RICA. LIMÓN: bord de la voie ferrée de l'Atlantique à Siquirres, 19 Nov. 1890, *Pittier 3154* (BR).

The relationships of this species with other members of *Zapoteca* are difficult to establish, espe-

FIGURE 42. Distribution of *Zapoteca andina*.

cially due to the paucity of material. On the basis of leaflet morphology and obscure leaflet venation patterns, *Z. costaricensis* is probably related to *Z. portoricensis* subsp. *flavida*. *Zapoteca costaricensis* can be easily distinguished from that entity, however, by its much larger leaflets and characteristic ovate/widely ovate, cordate stipules. The narrowly oblong leaflets of *Z. costaricensis* contrast with those of *Z. formosa*, which are almost always obovate.

12. Zapoteca formosa (Kunth) H. Hern., Ann. Missouri Bot. Gard. 73: 755 763. 1986. *Acacia formosa* Kunth, Mimoses 102, t. 32. 1822; Kunth, Nov. Gen. Sp. 6: 278. 1824; DC., Prodr. 2: 466. 1825. *Calliandra formosa* (Kunth) Benth., London J. Bot. 3: 98. 1844; Benth., London J. Bot. 5: 102. 1846; Benth., Trans. Linn. Soc. London 30: 542. 1875; Benth. in C. Martius, Fl. Bras. 5: 411. 1876; León, Contr. Ocas. Mus. Hist. Nat. Colegio "De la Salle" 10: 237. 1951. *Feuilleea formosa* (Kunth) Kuntze, Revis. Gen. Pl. 187. 1891. *Anneslia formosa* (Kunth) Britton & Millsp., Bahama Fl. 159. 1920; Britton & Rose, N. Amer. Fl. 23: 67. 1928. TYPE: Mexico, Guanajuato: *Bonpland 4288* (holotype, P, seen in microfiche; isotype, P). The label information on these specimens does not indicate the locality, but according to the description, it was collected in Guanajuato 1,068 hex (1,922 m) elevation. The holotype is extremely similar to and presumably served as the model for the illustration in Kunth's work (Fig. 43).

Erect shrubs to 5 m tall; stems erect, sometimes drooping, usually slender, sometimes to 5 cm diam.; branchlets terete to angular. Leaves eglandular, the pinnae 1–3(–4)-jugate; petioles terete, with a conspicuous adaxial channel, 0.3–7.8 cm long, glabrous to villous; rachis 0.3–6.8 cm long; rachillae 0.6–12.5 cm long; leaflets (2–)3–15 (–17) pairs per pinna, oblong to oblong-obovate or very widely obovate, the proximal ones sometimes

→

FIGURE 43. "*Acacia formosa*" (= *Zapoteca formosa* subsp. *formosa*), from Kunth's *Mimoses* t. 32. 1822. This plate was probably based on *Bonpland 4288*, a collection made in Guanajuato, Mexico.

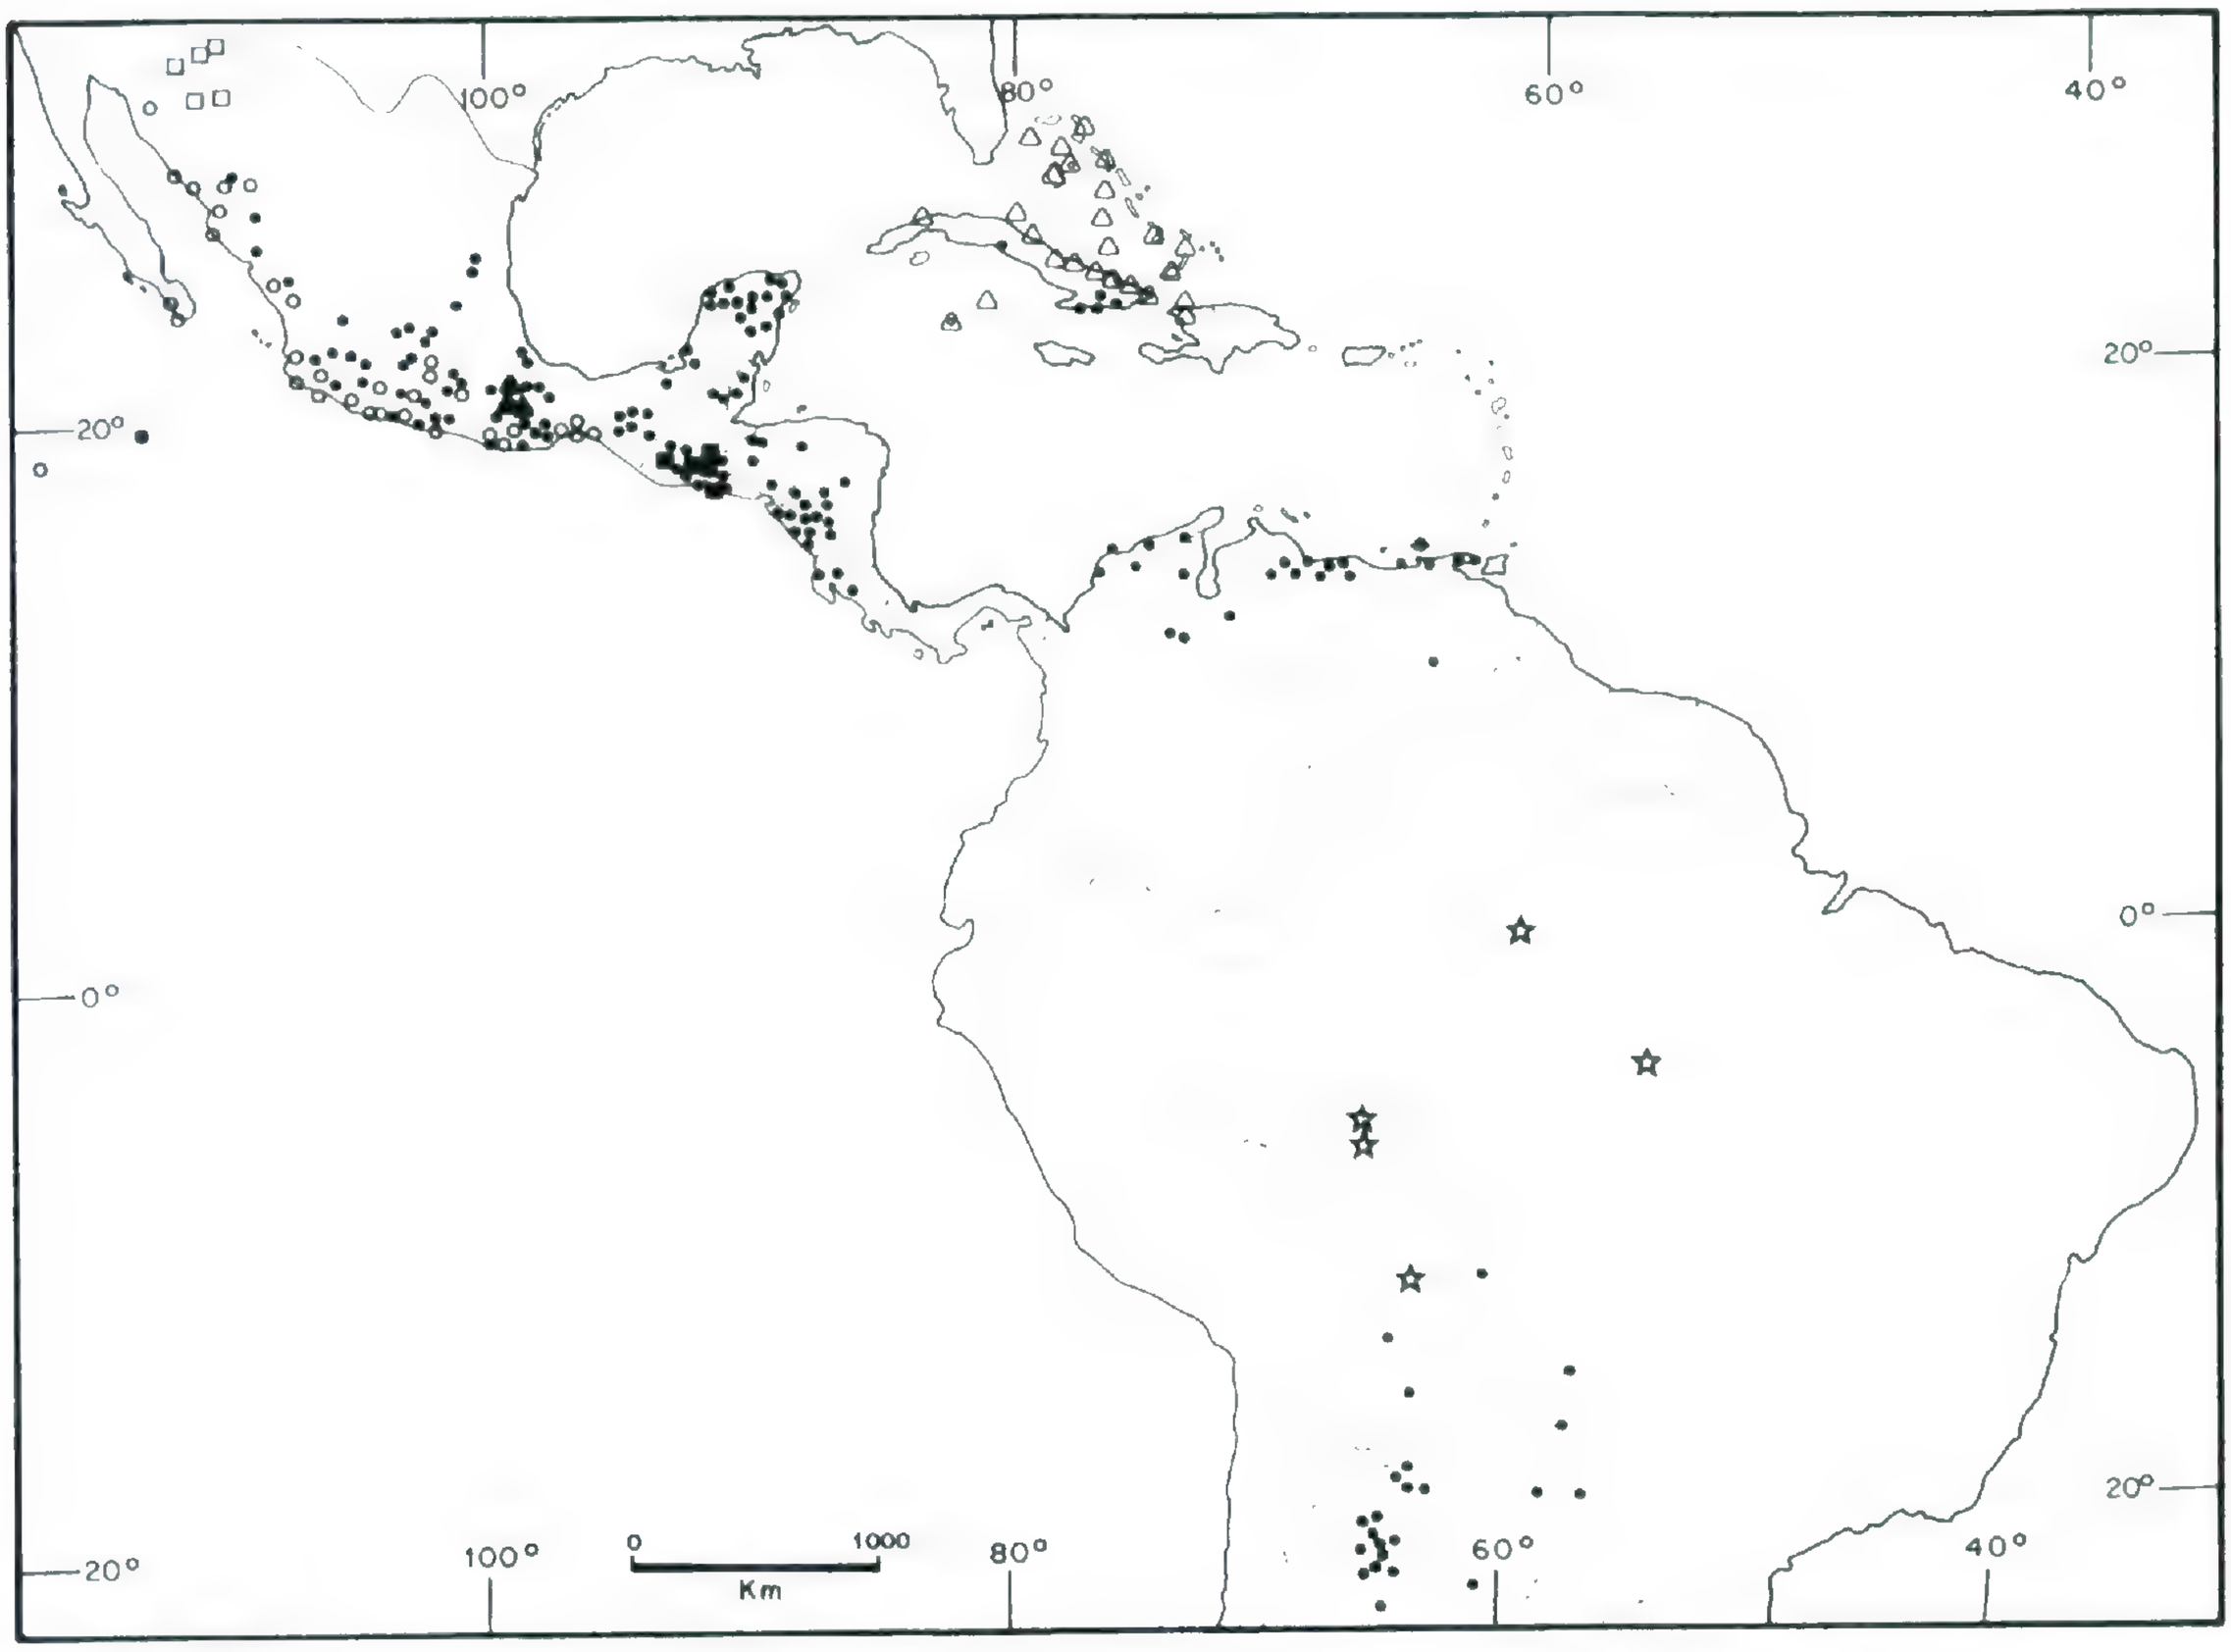

FIGURE 44. Distributions of *Zapoteca scutellifera* (stars), *Z. formosa* subsp. *formosa* (dots), *Z. formosa* subsp. *salvadorensis* (solid squares), *Z. formosa* subsp. *gracilis* (open triangles), *Z. formosa* subsp. *rosei* (open circles), *Z. formosa* subsp. *mollicula* (solid triangles), and *Z. formosa* subsp. *schottii* (open squares).

becoming elliptic or widely obovate, all oblique at the base or the proximal ones sometimes becoming acute, rounded to acute at apex, usually mucronate, the distal leaflets 0.4–5.9 × 0.2–3.6 cm, the proximal ones smaller, mostly membranous, glabrous to pubescent, pilose or villous; leaflet venation mostly inconspicuous, primary and secondary veins occasionally conspicuous; stipules leafy, triangular to linear-triangular, or lanceolate to ovate-lanceolate, to 13 mm long, glabrous to villous. Capitula axillary or in simple pseudopaniculate inflorescences; peduncles usually fasciculate at distant nodes, 1–11 cm long at anthesis. Flowers pentamerous; calyx cup-shaped, 1.5–4 mm long, glabrous, the teeth triangular to oblong-lanceolate; corolla campanulate, 3–5 mm long, glabrous, the lobes elliptic to lanceolate; filaments ca. 2.5–3 cm long, white, greenish white, red-purple, or white in the basal half and red-purple or pink in the distal half, the staminal tube ca. 1–3 mm long; ovary ca. 1–3 mm long, glabrous. Pods to 13(–15) cm long when mature, at apex truncate to rounded or acute, usually rostrate, thickly membranous, glabrous, glabrate or densely pilose. Seeds rhomboid-ovoid, sometimes very widely so, 4–8 × 3–6 mm, brown or gray, the areola usually lighter; pleurogram irregular, sometimes semiregular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 44). Usually common in disturbed or undisturbed habitats derived from arid scrub, tropical deciduous forests, and less frequently semievergreen forests. This species ranges from Arizona to Argentina and into the West Indies. Collections come from 0 2,000 m.

Zapoteca formosa as circumscribed here consists of six highly variable subspecies: *formosa*, *salvadorensis*, *gracilis*, *rosei*, *mollicula*, and *schottii*. This infraspecific classification is based primarily on leaf and flower characters (Table 14). Varying degrees of morphological intergradation occur between different pairs of subspecies. A total of 24 specific epithets have been published for plants that fall within *Z. formosa*. Most of these names really designate regional variations in leaflet characters. In light of the enormous degree of morphological variability within this widespread species and the relatively common occurrence of

TABLE 14. Comparison of the subspecies of *Zapoteca formosa*.

	Subspecies *formosa*	Subspecies *salvadorensis*	Subspecies *gracilis*	Subspecies *rosei*	Subspecies *mollicula*	Subspecies *schottii*

intermediates, a conservative approach has been chosen in this treatment. The following sequence of the subspecies reflects their putative relationships.

KEY TO THE SUBSPECIES OF *ZAPOTECA FORMOSA*

1a. Pods pilose; plants hairy throughout ..... 12b. subsp. *salvadorensis*
1b. Pods glabrous, rarely glabrate; plants glabrous to hairy.
2a. Filaments white or greenish white.
3a. Leaflets oblong, glabrous; stipules narrowly triangular, to 5 mm long ..... 12c. subsp. *gracilis*
3b. Leaflets oblong-obovate, glabrous to villous; stipule lanceolate to ovate-lanceolate, to 13 mm long ..... 12a. subsp. *formosa*
2b. Filaments either red-purple or white basally and red-purple or pink distally.
4a. Leaflets 4 14 × 2–9 mm; capitula axillary; filaments white basally and either pink or red-purple distally.
5a. Petioles 3–11 mm long ..... 12e. subsp. *mollicula*
5b. Petioles 12–35 mm long ..... 12f. subsp. *schottii*
4b. Leaflets 8–31 × 3 21 mm; capitula axillary or pseudopaniculate; filaments either wholly red-purple or white basally and red-purple to pink distally ..... 12d. subsp. *rosei*

12a. Zapoteca formosa (Kunth) H. Hern. subsp. **formosa**.

Calliandra capillata Benth., London J. Bot. 3: 98. 1844; Benth., Trans. Linn. Soc. London 30: 542. 1875. *Anneslia capillata* (Benth.) Britton & Rose, N. Amer. Fl. 23: 68. 1928. TYPE: Mexico. Oaxaca: ad radices Montis San Felipe, Julio, *Andrieux 404* (lectotype, K, here designated; isolectotypes, F (fragment), G, K, P).

Calliandra malacophylla Benth., London J. Bot. 3: 100. 1844; Benth., Trans. Linn. Soc. London 30: 544. 1875. TYPE: Mexico. Oaxaca: ad radices Montis San Felipe, Julio, *Andrieux 401* (lectotype, K, here designated; isolectotypes, F (fragment), G, K, P, US (fragment)).

Calliandra viridiflora Benth., London J. Bot. 3: 98. 1844; Benth., Trans. Linn. Soc. London 30: 542. 1875. TYPE: Brazil: *Tweedie s.n.* (lectotype, K, here designated; isolectotype, K).

Calliandra gracilis Klotzsch ex Baker, Refug. Bot. 5: t. 294. 1873, non Griseb., 1861, nec Standley, 1929, nec Renvoize, 1981; Benth., Trans. Linn. Soc. London 30: 542. 1875; L. Cárdenas, Revista Fac. Agron. (Maracay) 7: 131. 1974. *Calliandra formosa* var. *gracilis* (Klotzsch ex Baker) J. F. Macbr., Contr. Gray Herb. 59: 4. 1919. *Calliandra moritziana* L. Cárdenas, Ernstia 23: 40. 1984. (This name was published as a nomen novum for *Calliandra gracilis* Klotzsch ex Baker. The designation of *Moritz 887* (BM) as the lectotype made by Cárdenas is incorrect; the type collection is *Otto 404*, which Klotzsch explicitly cited in the original description of *C. gracilis*.) TYPE: Colombia: *Otto 404* (lectotype here designated, LE). The holotype, which presumably was at B, was probably destroyed in 1943 (P. Hiepko, pers. comm., 1986); additional duplicates of this collection were not found at GOET nor HBG.

Calliandra penduliflora Rose, Contr. U.S. Natl. Herb. 5: 193. 1899. *Anneslia penduliflora* (Rose) Britton & Rose, N. Amer. Fl. 23: 69. 1928. TYPE: Mexico. Jalisco: Bolaños, 10 19 Sept. 1897, *J. N. Rose 2924* (lectotype here designated, US no. 301875; isolectotypes, GH, K, NY).

Calliandra marginata Griseb. ex R. O. Williams, Fl. Trin. & Tob. 1: 299. 1931; Britton & Killip, Ann. New York Acad. Sci. 35: 137. 1936; L. Cárdenas, Revista Fac. Agron. (Maracay) 7: 131. 1974. *Anneslia marginata* (Griseb. ex R. O. Williams) Mold., Revista Sudamer. Bot. 6: 177. 1940. TYPE: British West Indies, Trinidad, *Crueger 326* (lectotype here designated, K; isolectotypes, NY, US). The specific epithet was provided by Grisebach in his *Fl. Brit. W.I.* 710. 1864.

Calliandra gentryi Standley, Field Mus. Nat. Hist., Bot. Ser. 17: 261. 1937; Gentry, Publ. Carnegie Inst. Wash. 527: 122. 1942. TYPE: Mexico. Chihuahua: Guasaremos, Río Mayo, Canyon Chanate, tropical Sonora, 5 Aug. 1936, *H. S. Gentry 2363* (holotype, F; isotypes, A, MEXU, MO, S, UC, US).

Anneslia chapaderoana Britton & Rose, N. Amer. Fl. 23: 69. 1928. TYPE: Guatemala. Santa Rosa: Chapadero, 5,000 ft., Aug. 1892, *Heyde & Lux 3740* (lectotype here designated, US no. 942577; isolectotype, G).

Anneslia cookii Britton & Rose, N. Amer. Fl. 23: 68. 1928. *Calliandra cookii* (Britton & Rose) Standley, Publ. Field Columbian Mus., Bot. Ser. 3: 277. 1930. TYPE: Guatemala. Petén: between Yaxmuxán and Yaxhá, 9 Apr. 1922, *Cook & Martin 209* (lectotype, here designated, US no. 1084668).

Anneslia izalcoensis Britton & Rose, N. Amer. Fl. 23: 69. 1928; León, Contr. Ocas. Mus. Hist. Nat. Colegio "De la Salle" 10: 237. 1951. TYPE: El Salvador. Sonsonate: vicinity of Izalco, in thicket, 19–24 Mar. 1922, *Standley 21818* (lectotype here designated, NY; isolectotypes, GH, US).

Anneslia orientalis Britton & Rose, N. Amer. Fl. 23: 69. 1928. *Calliandra orientalis* (Britton & Rose) León, Contr. Ocas. Mus. Hist. Nat. Colegio "De la Salle" 9: 7. 1950. TYPE: Cuba. Sevilla Estate, near Santiago, 27 Aug. 1906, *N. Taylor 4* (holotype, NY).

Anneslia suborbicularis Britton & Rose, N. Amer. Fl. 23: 69. 1928. TYPE: Mexico. Veracruz: Baños del Carrizal, Aug. 1912, *Purpus 6084* (lectotype here designated, NY; isolectotypes, F, GH, UC, US).

Anneslia yoroensis Britton, N. Amer. Fl. 23: 193. 1928. *Calliandra yoroensis* (Britton) Standley, Publ. Field Columbian Mus., Bot. Ser. 4: 309. 1929. TYPE: Honduras. Yoro: near Progreso, 30 m, wet thicket, 24 Jan. 1928, *Standley 55053* (lectotype here designated, NY; isolectotypes, A, F, US).

Erect shrubs to 3(5) m tall; stems usually slender, sometimes reaching 5 cm diam.; branchlets

generally ascending, sometimes drooping. Pinnae (1–)2–3(–4)-jugate; petiole 2.2–7.8 cm long; rachis 1.7–6.8 cm long; rachillae 2.6–8(–12) cm long; leaflets 3–8(–11) pairs per pinna, the distal leaflets 1.1–5.9 × 0.5–3.6 cm, oblong-obovate to very widely obovate, sometimes falcate, the proximal ones elliptic to widely obovate, the distal ones oblique at base, usually becoming acute proximally, rounded to acute at apex, usually mucronate, the proximal leaflets smaller, all glabrous to short-pubescent or finely villous; stipules lanceolate to ovate-lanceolate, sometimes slightly curved, to 10(–13) mm long, glabrous to pubescent or villous. Capitula axillary or in pseudopanicles to 22 cm long; peduncles 2.1–11 cm long at anthesis. Calyx 2–4 mm long, the teeth triangular to oblong-lanceolate, sometimes deeply divided; corolla 4–6 mm long; filaments white, sometimes greenish white. Pods to 13(–15) × 1(–1.2) cm, glabrous when mature, but occasionally villous or sparsely villous in early developmental stages. Seeds rhomboid-ovoid to widely so, 6–7 × 3–6 mm, brown, the areola usually lighter; pleurogram strongly irregular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 44). This subspecies has the widest distribution within *Z. formosa*. Its range extends from northern Mexico, in the states of Tamaulipas, Chihuahua, and Sinaloa, south and southeast through Central America to central Costa Rica. In South America it occurs in northern Venezuela and northern Colombia, and also in Brazil (Minas Gerais), Bolivia, Paraguay, and northern Argentina. It has been collected on Cuba, Trinidad, and other smaller islands in the West Indies. This subspecies has not been collected in Panama, most of Colombia, Ecuador, or Peru. It is relatively common in open sites in seasonal, dry environments such as tropical dry forests, coastal thickets, and arid thorn scrub, although occasionally it is found in wetter disturbed or undisturbed habitats, in semi-evergreen or evergreen tropical or subtropical forests. It has also been collected occasionally in pine and pine–oak forests in Mexico. Collections come from altitudes of 0–2,000 m. Cultivated individuals in Guanajuato, Mexico yielded the collection *Dugès s.n.*

Common names. Bellotica (Atlántico, Colombia), caba pixoy (Yucatán), cabellera (Oaxaca), chipilín de monte (Guatemala), chapuli (Guerrero), claveyino (Chihuahua), barbón montañés (El Salvador), huaje (Sinaloa), ibche (Yucatán), tamanché (Yucatán), tepehuaje (Guanajuato), veranero (Bolívar, Colombia), yag civ (Oaxaca), yaque (Sucre, Venezuela).

Additional specimens examined. MEXICO. CAMPECHE: alrededores de las Grutas de Xtacumbilxunam, a 3 km W de Bolonchén de Rejón, *Cabrera & Cabrera 9514* (MEXU); 8 km SE de Conhuas sobre el camino al Centro Regional Calakmul, en km 99 de la carr. Escarcega-Chetumal, *Cabrera & Cabrera 10973* (MEXU); Reforma, *Lundell 835* (CAS, F, GH, MICH, MO, NY, UC, US, WIS); Tuxpeña, *Lundell 1073* (F). W de Zumpango del Río, *Rico & Funk 201* (CAS, MEXU).

Zapoteca formosa subsp. *formosa* is the most widespread and morphologically variable subspecies within the species. Fourteen names have been published that fall within the boundaries of this subspecies as I have defined it; most of them have been based primarily on regional variations in leaflet morphology and vestiture. These characters, along with the size of the flower parts and pods, are highly variable at an inter- and intrapopulation level, especially in the Mexican and Central American populations, and thus they are not useful taxonomically. Perhaps the most variable character is leaflet size, but the variation does not correspond to a geographical pattern. A similar situation occurs with variation in leaflet vestiture; plants with short-pubescent or villous leaflets occur in the same areas as plants with glabrous leaflets throughout most of the range. In addition there is continuous variation in leaflet apex morphology, ranging from rounded to acute. Plants from the southern limits of this subspecies are comparatively consistent morphologically. In this area, they usually have medium to relatively small leaflets, and the number of pairs of leaflets per pinna is quite regular.

The entity most closely related to *Z. formosa* subsp. *formosa* appears to be the Central American subsp. *salvadorensis*, which is distinguished by its densely pilose pods. *Zapoteca formosa* subsp. *formosa* is consistent in having glabrous pods, although in El Salvador and Venezuela, plants with glabrate pods have been collected. In a few collections of subsp. *formosa* from Oaxaca, Jalisco, Honduras, Venezuela, and Cuba, the pods are pilose or sparsely pilose when very young, but soon become glabrous.

Zapoteca formosa subsp. *formosa* also appears closely allied to subsp. *rosei*, from which it differs by having white or white-green filaments (Table 14). Plants of subsp. *formosa* also usually have larger leaflets and are generally more robust than those of subsp. *rosei*. In a number of instances, however, the identification of these two subspecies is troublesome if flowers are not available or if filament color is not known. In some areas of the Mexican Pacific slope, especially in the state of Guerrero, where these two subspecies presumably occur sympatrically, hybridization probably takes place, resulting in morphological intergradation. In this area, many collections of subsp. *rosei* have larger leaflets than normal in this entity, thus resembling those of subsp. *formosa*. Such areas of intergradation are in Tecpan de Galeana (e.g., *Hinton 14335, 10894, Ladd et al. 206*) and Zihuatanejo (e.g., *Tenorio et al. 398, Ladd et al. 216, Sousa 6159*). Similarly, in some localities of the District of Yautepec in Oaxaca, plants from the two subspecies have been found growing together (e.g., *H. Hernández & Torres 216, 217, Téllez Magallanes 111, 113*). The collections belonging either to *Z. formosa* subsp. *formosa* or to subsp. *rosei*, but of ambiguous identity, are listed separately under *Z. formosa* subsp. *formosa*.

Zapoteca formosa subsp. *formosa* is distinguishable from the West Indian subsp. *gracilis* by having oblong-obovate leaflets, usually larger, lanceolate to ovate-lanceolate stipules, and glabrous, pubescent, or villous leaflets, which contrast with the consistently glabrous ones of subsp. *gracilis*. Subspecies *formosa* differs from subsp. *mollicula* and subsp. *schottii* by its more robust habit, white filaments, and larger petioles, leaflets, stipules, flower parts, and pods (Table 14).

There is a wide disjunction in the South American distribution of *Z. formosa* subsp. *formosa*, from northern Colombia and Venezuela to Bolivia, southeastern Brazil and Paraguay (Fig. 44). Morphologically, the populations from the southern region clearly belong to the subspecies. Perhaps this geographical fragmentation is related to the current scarcity of relatively dry, seasonal, lowland habitats in the intervening region. As reviewed by Haffer (1982, and references therein), climatic fluctuations during the Pleistocene had a great

effect in tropical areas. In lowland areas of the Neotropics, alternating periods of cooler and drier climates probably caused extinction or displacement of species adapted to the warm-wet forest conditions during the interglacial periods, and only a few areas (forest refugia) remain relatively unchanged. Consequently, great expanses of wet forests were replaced by drier, more open vegetation in the Amazon Basin (Ab'Saber, 1982; Absy, 1982; Bigarella & Andrade-Lima, 1982; van der Hammen, 1982; Prance, 1982; and others). In light of this body of ideas, it can be postulated that the populations of *Z. formosa* subsp. *formosa* found a more suitable environment during the dry phases of the Pleistocene, and then were continuously distributed across the Amazon Basin; and that the present-day disjunction in South America is the result of fragmentation of a formerly more continuous range after the warm, wet present-day conditions were established.

12b. Zapoteca formosa subsp. **salvadorensis** (Britton & Rose) H. Hern., comb. et stat. nov. *Anneslia salvadorensis* Britton & Rose, N. Amer. Fl. 23: 68. 1928. TYPE: El Salvador: vicinity of San Salvador, 650 850 m, 2–7 Feb. 1922, *Standley 20452* (lectotype, NY, here designated; isolectotypes, GH, MO, US).

Erect shrubs to 4 m tall, usually finely to densely villous throughout, except for the flowers. Pinnae 2–3-jugate; petioles (1.8–)3.1–4.5 cm long; rachis (0.9–)1.6–4 cm long; rachillae (1.8)3.8 5.6 cm long; leaflets 4–6 pairs per pinna, oblong-obovate, oblique at base, rounded to acute at apex, usually mucronate, the distal leaflets 1.6 2.6 × 0.7–1.9 cm, the proximal ones smaller; stipules lanceolate, sometimes curved, to 1.2 cm long. Capitula usually axillary, occasionally in simple pseudopanicles to 7 cm long; peduncles 2.2 8.2 cm long at anthesis. Calyx 3–4 mm long, the teeth oblong-lanceolate, glabrous; corolla ca. 5 mm long, glabrous; filaments white. Pods to 9 × 0.8 cm, pilose to densely pilose with white hairs. Seeds rhomboid-ovoid, ca. 5 × 4 mm, sometimes red when immature, brown when mature, the areola lighter; pleurogram irregular.

Distribution (Fig. 44). Endemic to southern Guatemala and El Salvador, where it has been collected in the departments of El Progreso, Chiquimula, Quiché, Sololá, and Zacapa, Guatemala, and near San Salvador, El Salvador. It has been collected primarily in disturbed, brushy habitats at altitudes of 300 1,800 m.

Additional specimens examined. GUATEMALA. CHIQUIMULA: between Chiquimula and Sta. Rosalía, *Molina & Molina 25136* (F, MO, US); near divide on road from Zacapa to Chiquimula, *Standley 73743* (F). EL PROGRESO: Motagua Valley, *Breckon & Breckon 2118* (ENCB, MEXU, NY). QUICHÉ: near village of Río Blanco, *Williams et al. 22456* (BM, F, GH, NY, US). SOLOLÁ: village of San Pedro, Volcán San Pedro, north-facing slopes towards Lago de Atitlán, *Steyermark 47203* (F). ZACAPA: Río Hondo, base of Sierra de las Minas, *Standley 73979* (F); Río Hondo, *Steyermark 29494* (F).

Zapoteca formosa subsp. *salvadorensis* is closely related to subsp. *formosa*, from which it can be distinguished by having pilose or densely pilose pods and by being villous on all vegetative parts. By contrast, presence or absence of vestiture in subsp. *formosa* is expressed irregularly throughout its range. Geographically, these two subspecies are allopatric.

12c. Zapoteca formosa subsp. **gracilis** (Griseb.) H. Hern., comb. et stat. nov. *Calliandra gracilis* Griseb., Mem. Amer. Acad. Arts 8: 180. 1861, non Klotzsch, 1871, nec Standley, 1929, nec Renvoize, 1981. *Anneslia grisebachii* Britton & Rose, N. Amer. Fl. 23: 67. 1928. This was published as a nomen novum, because the name *Anneslia gracilis* was preoccupied by Britton & Rose for a species based on *Acacia gracilis* M. Martens & Galeotti (see synonymy under *Z. formosa* subsp. *rosei*). *Calliandra grisebachii* (Britton & Rose) Standley, Publ. Field Columbian Mus., Bot. Ser. 3: 277. 1930. *C. grisebachii* (Britton & Rose) León, Contr. Ocas. Mus. Hist. Nat. Colegio "De La Salle" 10: 237. 1951; Liogier, Fl. Cuba (Supl.). 72. 1969. TYPE: Prope Cuba Orientali, Sep. 1859 Jan. 1860, *Wright 151* pro parte (lectotype here designated, GH; isolectotypes, CGE, F, G, LE, MO). As León (1951; see synonymy below) pointed out, *Wright 151* includes two elements under the same number. In addition to the specimens considered here to represent the type of this taxon, there are five collections, also numbered as *151*, at G, GH, LE, NY (fragment), and S, that presumably came from another locality and belong to *Z. formosa* subsp. *formosa*. One additional specimen at G includes material from both.

Calliandra comosa Griseb., Cat. Pl. Cub. 83. 1866, non Benth., 1846. *Calliandra formosa* var. *cubensis* J. F. Macbr., Contr. Gray Herb. 59: 4. 1919. (Based on the same type as *Calliandra comosa.*) *Anneslia cubensis* (J. F. Macbr.) Britton & Rose, N. Amer. Fl. 23: 68. 1928. *Calliandra cubensis* (J. F. Macbr.) León, Contr. Ocas. Mus. Hist. Nat. Colegio "De La Salle" 9: 7. 1950; León, Contr. Ocas. Mus. Hist. Nat. Colegio "De La Salle" 10: 237. 1951; Liogier,

Fl. Cuba (Supl.). 72. 1969; Proctor, Kew Bull. 11: 481. 1984. TYPE: Cuba: *Wright 2406* (lectotype here designated, GH).

Erect shrubs to 2(5) m tall, glabrous throughout. Pinnae 2–3(–4)-jugate; petioles 1.3–5.5 cm long; rachis 0.7–5 cm long; rachillae 3.5–12.5 cm long; leaflets (5–)7–15 pairs per pinna, the median ones elliptic to elliptic-oblong, the distal ones oblique at the base, the proximal ones becoming acute, rounded to subacute, rarely acute at apex, sometimes mucronate, the median leaflets 9–22 × 3.5–11 mm, all usually drying light green; stipules linear-triangular, to 5 mm long. Capitula axillary; peduncles 3.5–10.5 cm long at anthesis; calyx 2.5–3 mm long; corolla 5–6 mm long; filaments white. Pods to 11 × 1.2 cm, glabrous. Seeds ovoid, 5–6 × 3–4 mm, usually mottled, pleurogram semiregular.

Distribution (Fig. 44). Restricted to several islands of the West Indies: Cuba, Bahamas, Cayman Islands, and Haiti, where it primarily occurs in rocky, calcareous areas, in dense thickets, and, in general, in secondary, arid habitats at elevations of 0–600 m.

Additional specimens examined. BAHAMA ARCHIPELAGO. ABACO: Eight Mile Bay, *Brace 1854* (F, NY). ANGUILLA ISLAND: south end, *Wilson 8025* (F, NY). ANDROS: road to Morgan's Bluff, *Brace 6661* (F, NY); Behring Point, *Godfrey 41444* (NY); South Andros, S of Little Creek, *Correll 43481* (NY); 2 mi. E of Andros Town airport, *Hill 3003* (NY); Mangrove Cay, near Lisbon Creek, *Small & Carter 8439* (F, GH, NY, US). BERRY ISLAND: Whale Cay, *Britton & Millspaugh 2183* (F, NY); Goat Cay, *Britton & Millspaugh 2288* (F, NY); Anderson Cay, Great Harbour Cay, *Correll 43687* (F, NY). BIMINI ISLANDS: South Bimini, *Correll 42174* (LL, NY); Bimini, Cat Cay, *Correll 45614* (NY); South Bimini, NE corner of Island, *Gillis 11295* (F). CAICOS ISLANDS: Long Cay, N end, *Millspaugh & Millspaugh 9235* (F, CAS, NY); Long Cay, S end, *Millspaugh & Millspaugh 9274* (F, NY, US); South Caicos, *Wilson 7690* (F, GH, K, NY). CAT ISLAND: Bennets Harbor, *Byrne 358* (A, WIS); Zonicle Hill, *Correll 16065* (NY). ELEUTHERA: Glass Window to Harbor Island, *Britton & Millspaugh 5393* (F, NY); North Eleuthera, near Watkins Hill, *Correll 41060* (MO); 6 mi. N of James Cistern, *Correll & Hill 45234* (NY). EXUMA CHAIN: Little Galiot Cay, *Britton & Millspaugh 2843* (F, GH, NY, US). INAGUA: Great Inagua, Rocky Point, *Correll 17171* (MO, NY). LONG ISLAND: Clarence Town, *Britton & Millspaugh 6291* (F, NY). NEW PROVIDENCE: near Nassau, *Curtis 83* (A, F, G, GH, MO, NY, US); Blue Hills, between Lake Cunningham and Lake Killarney (77°24.5′W, 25°03.5′N), *Webster et al. 10511A* (GH, US); Hog Island, *Wilson 8272* (F, NY). RAGGED ISLANDS: Great Ragged Island, *Wilson 7806* (F, NY). ROSE ISLAND: *Britton & Millspaugh 2149* (F, NY). CAYMAN ISLANDS: near Tibbett's Turn, *Proctor 29355* (LL); 0.8–1 km inland from Spot Bay, *Proctor 35189* (US). CUBA: CAMAGUEY: Cayo Sabinal, between Corte Ficote and El Fuerte, *Ekman 15539* (US); La Gloria, near Laguna Grande, *Shafer 602* (GH, NY, US); Santa Lucia, *Shafer 974* (GH, NY, US); Cayos Canal Nuevo, Cayo Lagua, *Shafer 2668* (F, NY, US); Cayo Guajaba, hills NW end, *Shafer 2855* (F, GH, NY, US); vicinity of Tiffini, *Shafer 2901* (F, NY, US). ORIENTE: Punta Piedra, Nipe Bay, *Britton et al. 12471* (NY, US); Río del Medio, Jauco region, *León 12426* (GH, US); Loma de Tabaco, Manatí Bay, *León & Alain 18937* (GH, US); Holguin to Myabe, *Shafer 1410* (NY, US); northward of Raimon, Nipe Bay, *Shafer 1792* (NY). PINAR DEL RÍO: Pan de Guajaibón, La Mulata, *Barker 18513* (NY); Pan de Guajaibón, *Alain & Acuña 2995* (NY); Sierra de Nipe, Río Piloto, *Ekman 5780* (G); Banes, prope Puerto Rico, *Ekman 6607* (NY). HAITI: Ile de Nord-Ouest, Port de Paix, *Ekman 2846* (NY, US); E of La Vallée, Tortue Island, *Leonard & Leonard 11312* (A, GH, NY, US). CULTIVATED: U.S.A. FLORIDA: Miami, Fairchild Tropical Garden, *Gillis 8672* (MO).

Zapoteca formosa subsp. *gracilis* is relatively uniform morphologically compared with the other subspecies of *Z. formosa*. It is related to subsp. *formosa*, from which it is distinguished by having elliptic to elliptic-oblong leaflets and narrowly triangular stipules and by being glabrous (Table 14). The seeds of subsp. *gracilis* differ from those of the remaining subspecies of *Z. formosa* by having semiregular, instead of irregular, pleurograms. Subspecies *gracilis* and subsp. *formosa* are essentially allopatric, although there are a few collections of both from Oriente Province, Cuba. Their relationship is discussed further under *Z. formosa* subsp. *formosa*.

Although leaflet morphology is quite constant among populations of *Z. formosa* subsp. *gracilis*, a few plants from the Bahamas (e.g., *Correll & Correll 45614*, *Curtis 82*, *Gillis 11295*, *Hill 3003*) have unusually narrow leaflets. These plants could be confused with *Z. portoricensis* but can be readily distinguished by their smaller and narrower stipules and relatively thicker leaflets (also see Table 14). In addition, *Z. formosa* and *Z. portoricensis* are strongly segregated geographically in the West Indies.

12d. Zapoteca formosa subsp. **rosei** (Wiggins) H. Hern., comb. nov. *Calliandra rosei* Wiggins, Contr. Dudley Herb. 4: 17. 1950. *Calliandra schottii* subsp. *rosei* (Wiggins) Felger & Lowe, J. Ariz. Acad. Sci. 6: 83. 1970. *Acacia gracilis* M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 10: 311. 1843. *Anneslia gracilis* (M. Martens & Galeotti) Britton & Rose, N. Amer. Fl. 23: 68. 1928. *Calliandra gracilis* (M. Martens & Galeotti) Standley, Publ. Field Columbian Mus., Bot. Ser. 4: 309. 1929, non Griseb., 1861, nec Klotzsch, 1871, nec Renvoize, 1981. H.

S. Gentry, Publ. Carnegie Inst. Wash. 527: 122. 1942 TYPE: Mexico. Oaxaca: bord del l'Océan Pacifique, Oct. 1840, *Galeotti 3190* (holotype, BR (not seen); isotypes, G, K, LE).

Calliandra socorrensis I. M. Johnston, Contr. Gray Herb. 70: 71. 1924. *Anneslia socorrensis* (I. M. Johnston) Britton & Rose, N. Amer. Fl. 23: 64. 1928. TYPE: Mexico. Colima: Isla Socorro, Mar. June 1897, *A. W. Anthony s.n.* (holotype, UC no. 83534). In a later note, Johnston (Proc. Calif. Acad. Sci. 20: 62. 1931.) pointed out that Anthony made two unnumbered collections on Socorro Island. Since he implied that they were made from different localities, the second collection, also at UC (no. 89257), should not be considered an isotype.

Anneslia delicata Britton & Rose, N. Amer. Fl. 23: 67. 1928. TYPE: Mexico. Baja California Sur: San José del Cabo, 23 Sep. 1890, *T. S. Brandegee 196* (lectotype, NY, here designated; isolectotypes, A, GH, NY, UC (2), US).

Anneslia interior Britton & Rose, N. Amer. Fl. 23: 66. 1928. TYPE: Mexico. Durango: mountains of southern Durango, 15 Aug. 1897, *Rose 2317* (lectotype US no. 301227, here designated; isolectotype, NY).

Shrubs to 3(–4) m tall; stems usually slender, erect or drooping. Pinnae 1–3-jugate; petioles 1–4.2(–5) cm long; rachis 0.3–3.4 cm long; rachillae 1.9–6.5(–11.3) cm long; leaflets (3–)4–12(–17) pairs per pinna, distal leaflets oblong-obovate to oblong–very widely obovate, rarely oblong, the proximal ones sometimes becoming elliptic, the distal leaflets oblique at base sometimes becoming acute proximally, rounded to acute at apex, usually mucronate, 8 31 × 3 21 mm, usually becoming smaller proximally, glabrous to villous; stipules lanceolate to ovate-lanceolate, to 9 mm long, glabrous to villous. Capitula axillary, sometimes in simple pseudopanicles to 13.5 cm long; peduncles 1 4.7 (–5.8) cm long at anthesis. Calyx 1.5 2 mm long, glabrous, the teeth triangular to oblong-lanceolate; corolla 3–5 mm long, glabrous; filaments red-purple, or white in the basal half and red-purple or pink in the distal half. Pods to 9 × 0.9 cm at maturity, glabrous. Seeds rhomboid-ovoid to widely rhomboid-ovoid, 4–5 × 4 mm, brown or gray, the areola lighter usually; pleurogram irregular. Somatic chromosome number $2n = 26$.

Distribution (Fig. 44). This subspecies occurs along the Pacific slope of Mexico, from northern Sonora south and southeast to the Isthmus of Tehuantepec. It has also been collected in southern Baja California and on the Revillagigedo Islands (Isla Socorro and Isla Clarión). A number of collections have been made from the districts of Yautepec and Tlacolula, Oaxaca, and from a number of localities in the Balsas Basin. It is relatively common in disturbed or undisturbed habitats of tropical thorn woodlands and tropical deciduous or tropical semievergreen forests. It is found on steep calcareous slopes, on volcanic rock, or along the margins of seasonal streams at 0–1,430 m.

Common names. Huaje de caballo (Oaxaca), tosapolo (Sonora).

Additional specimens examined. MEXICO: BAJA CALIFORNIA SUR: 6 10 mi. SE of Todos Santos Cabo San Lucas hwy., on small road to Rancho La Burrera, *Breedlove & Axelrod 43213* (CAS, MEXU). Obregón, *Gentry 14488* (LL, US); San Bernardo and vicinity, Arroyo Gochico, *Gentry et al. 19286* (US); Hacienda de San Miguel, near Batopilas, *Palmer 16* (BM, GH, K, MEXU, NY, US).

This polymorphic, highly variable subspecies, along with *Z. formosa* subsp. *formosa*, represents the phylogenetic core within the species. Leaflet size is highly variable within and between populations, and a clinal variation pattern is evident, especially in the northern portion of its range, possibly a reflection of decreasing precipitation from south to north. There is some variation in filament color within *Z. formosa* subsp. *rosei*, although this character is consistent at the populational level. The distribution of the different color morphs is not known with precision. The following generalizations can, however, be drawn: the most widespread pattern of filament color is the white/red-purple pattern, which occurs from southern Oaxaca to Sonora and Chihuahua. The populations from the Isthmus of Tehuantepec, at the eastern distributional limit (e.g., *H. Hernández & Ramírez 918*, *Sousa & Téllez 8687*), and a few populations from Michoacán (e.g., *H. Hernández & Chacón 185*, *Soto 1636*) have entirely red-purple filaments. Populations from the districts of Tlacolula and Yautepec, Oaxaca, have white/pink filaments (e.g., *H. Hernández & Ramírez 930, 943*).

Zapoteca formosa subsp. *rosei* is closely related to subsp. *formosa* and to subsp. *mollicula* and subsp. *schottii*. It can be distinguished from subsp. *formosa* by the color of its filaments and by its usually smaller leaflets. However, plants of these two subspecies sometimes resemble each other closely. In some localities of Guerrero, the two subspecies become sympatric and apparently intergrade morphologically. These collections are not assigned to a particular subspecies; they have been listed separately under subsp. *formosa* (and see discussion under this subspecies).

As will be discussed below under the respective subspecies, patterns of morphological variation, especially in leaflet size, are essentially continuous between *Z. formosa* subsp. *rosei* on the one hand and subsp. *mollicula* and subsp. *schottii* on the other. Although each of these is relatively easily identifiable, their integrity breaks down because of the existence of morphological intermediates. *Zapoteca formosa* subsp. *rosei* can be distinguished from subsp. *mollicula* by having more-developed leaf parts (e.g., longer petioles and rachillae, usually more numerous and larger leaflets, and usually larger stipules (Table 14)). Similarly, subsp. *rosei* can be distinguished from subsp. *schottii* primarily

by having more numerous and larger leaflets (Table 14). Nevertheless, the differences between these two subspecies are less marked than those separating subsp. *rosei* and subsp. *mollicula*. Geographically, subsp. *mollicula* and subsp. *schottii* are peripheral to but contiguous with subsp. *rosei*. This fact, along with their close morphological affinities, suggests that subsp. *mollicula* and subsp. *schottii* were derived from subsp. *rosei*. Further discussion of the presumed relationships of these three taxa is provided under the respective subspecies.

12e. Zapoteca formosa subsp. **mollicula** (M. Martens & Galeotti) H. Hern., stat. et comb. nov. *Acacia mollicula* M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 10: 313. 1843. *Anneslia mollicula* (M. Martens & Galeotti) Britton & Rose, N. Amer. Fl. 23: 64. 1928. *Calliandra mollicula* (M. Martens & Galeotti) Standley, Publ. Field Columbian Mus., Bot. Ser. 4: 309. 1929. TYPE: Mexico. Puebla: Plaine de Tehuacán, 5,500 ft., *H. Galeotti 3216* (lectotype here designated, BR).

Calliandra unijuga Rose, Contr. U.S. Natl. Herb. 5: 193. 1899. *Anneslia unijuga* (Rose) Britton & Rose, N. Amer. Fl. 23: 64. 1928. TYPE: Mexico. Oaxaca: Cuicatlán, 1,800 ft., 24 Sep. 1894, *L. C. Smith 203* (lectotype here designated, GH; isolectotypes, US 2 fragments).

Calliandra unijuga var. *pueblensis* J. F. Macbr., Contr. Gray Herb. 59: 4. 1919. TYPE: Mexico. Puebla: vicinity of San Luis Tultitlanapa, near Oaxaca, Barranca de Tlacuilosto, June 1908, *C. A. Purpus 3185* (lectotype, F, here designated; isotypes, BM, GH, NY, MO, UC, US (2)).

Erect shrubs to 2(–2.5) m tall; stems slender, sometimes with exfoliating bark; branchlets pilose in the younger parts, glabrate, sometimes glabrous throughout. Pinnae 1(2)-jugate; petioles 3 11 mm long; rachis 4–8 mm long; rachillae 6–18 mm long; leaflets (2–)3–5(–6) pairs per pinna, oblong-obovate to widely obovate, rarely elliptic, the distal ones oblique at base, 4–14 × 2–9 mm, the proximal ones smaller, becoming rounded or acute, rounded or rarely retuse at apex, usually mucronate, all membranous, finely pilose or villous to totally glabrous; stipules lanceolate to ovate-lanceolate, sometimes narrowly triangular, to 3 mm long, finely pilose to glabrous, usually ciliate. Capitula axillary; peduncles (1.2–)2.3–4.5 cm long at anthesis. Calyx ca. 2 mm long, the teeth triangular, glabrous; corolla ca. 5 mm long; filaments white in the basal half, red-purple in the distal half. Pods to 7.5 × 0.8 cm at maturity, glabrous. Seeds ovoid, ca. 5 × 4 mm, brown; pleurogram irregular.

Distribution (Fig. 44). Endemic to the Tehuacán and Cuicatlán valleys in the states of Puebla and Oaxaca, where it primarily occurs on dry, calcareous slopes, in arid scrub and tropical dry forests at 550–1,450 m.

Common name. Huajillo (Puebla).

Additional specimens examined. MEXICO. Zapoteca formosa subsp. *mollicula* represents an extreme of morphological variation within the species in petiole length, number of pairs of pinnae, and number and size of leaflets. It is distinguished from the other subspecies by its 1-, rarely 2-jugate pinnae with fewer and smaller leaflets and by its somewhat shorter internodes. Leaflet size, however, is extremely variable in this subspecies, both at an intra- and interpopulational level (e.g., *Cruz Cisneros 2563, H. Hernández & Torres 218, Rose & Hough 4671, Sousa et al. 6904, 6905*). Similarly, vestiture is highly variable, and does not display any coherent pattern.

Zapoteca formosa subsp. *mollicula* clearly is closely related to the highly variable subsp. *rosei*. Perhaps the most taxonomically meaningful characters separating these taxa are the usually more reduced leaves of subsp. *mollicula*. However, variation in leaf characters (e.g., petiole length, number of pinnae, number of leaflets, size of leaflets) is essentially continuous, especially when plants of subsp. *rosei* from the districts of Tlacolula and Yautepec, Oaxaca (e.g., *Delgado et al. 724, H. Hernández & Torres 207, 210, 212, 215, 217, Hernández & Ramírez 930, 932, 943, Magallanes et al. 199, Sousa et al. 6549*) are compared

with some plants of subsp. *mollicula* (e.g., *Cruz Cisneros 2563*, *Hernández & Torres 218*, *Hernández & Ramirez 874*, *876*, *877*, *Rose & Hough 4671*, *Sousa et al. 6904*, *6905*).

12f. Zapoteca formosa subsp. **schottii** (Torrey ex S. Watson) H. Hern., comb. nov. *Calliandra schottii* Torrey ex S. Watson, Proc. Amer. Acad. Arts 20: 364. 1885. "*Calliandra portoricensis* Benth. var." Torrey, Emory Rep. 2: 61. 1859; Isely, Madroño 21: 280. 1972. This species was doubtfully referred to in Torrey's *Botany of the United States and Mexican Boundary Survey* (loc. cit.) as "*Calliandra* (*portoricensis* Benth. var.)." Subsequently, S. Watson based his *Calliandra schottii* on the description provided by Torrey, citing a Pringle collection (*272*). *Anneslia schottii* (Torrey ex S. Watson) Britton & Rose, N. Amer. Fl. 23: 67. 1928. *Calliandra schottii* subsp. *schottii* (Torrey ex S. Watson) Felger & Lowe, J. Ariz. Acad. Sci. 6: 83. 1970. TYPE: Mexico. Sonora: Pimeria Alta, Sierra Verde, Arroyo de los Samotas, 20 Aug. 1855, *Schott s.n.* (lectotype designated by Isely (Madroño 21: 280. 1972), GH; isolectotypes, NY (2), US (fragment)).

Erect shrubs to 1.5(2) mm tall; stems slender, densely branched; branchlets glabrous to finely pilose. Pinnae 1–2-jugate; petioles 1.2–3.5 cm long; rachis 0.4- 1.7 cm long; rachillae 1.9–4.5 cm long. Leaflets (3–)4–6(7) pairs per pinna, oblong-obovate, 4–12(–14) × 2–6(–7) mm, oblique at base, rounded to acute at apex, usually mucronate, membranous, glabrous to finely pubescent; stipules narrowly triangular to lanceolate, sometimes slightly curved, to 5 mm long, glabrous to finely pubescent. Capitula axillary; peduncles 1.8–4.5(–6) cm long at anthesis. Calyx ca. 1.5–2 mm long, glabrous, the teeth triangular-lanceolate; corolla ca. 3 mm long; filaments white in basal half, pink in distal half. Pods to 7 × 0.6 cm at maturity, glabrous, rarely very sparsely and minutely pilose. Seeds rhomboid-ovoid, 5–8 × 3.5–5 mm, brown, the areola lighter; pleurogram irregular.

Distribution (Fig. 44). Endemic to rocky, arid slopes in a few localities of the northern portion of the Sonoran Desert in Pima County, Arizona (e.g., Baboquivari Mts., Santa Catalina Mts.) and northern Sonora at 1,100–1,400 m. This subspecies occupies the northernmost part of the distribution of the species.

Additional specimens examined. U.S.A. ARIZONA: Pima Co. W of Tucson, Robles Pass, *Bartram 409* (US); Coyote Mountains, *Goodding 24-57* (CAS); Moristo Canyon, Baboquivari Mountains, *Goodding 247-45* (NY); Baboquivari Canyon, Baboquivari Mountains, *Gould & Haskell 3253b* (CAS, F, GH, MO, NY); Catalina Mountains, Sabino Canyon, *Jones s.n.* (CAS, F, GH, MO, NY, UC, US); Toro Canyon, Baboquivari Mountains, *Kearney & Peebles 10397* (CAS, MICH); South Canyon, *Kearney & Peebles 14960* (CAS, GH, NY, US); 5 mi. below Federal Prison Camp Headquarters, Santa Catalina Mts., *Parker et al. 5861* (GH, NY, UC). MEXICO: SONORA: Sierra Jojoba, *Gentry & Webber 21985* (A, US); northwestern Mts., *Pringle 272* (US); 17.7 mi. SE of Magdalena, *Starr & Birgy 169* (MEXU); Cañón de Agua Amarga, *White 3609* (MICH?, GH).

Zapoteca formosa subsp. *schottii* is closely related to and was probably derived from subsp. *rosei*. The former has generally smaller stature, less numerous, smaller leaflets, and smaller pods (Table 14). These two taxa show geographically contiguous distributions (Fig. 44), and there is clinal variation in leaflet size, with subsp. *schottii* occupying the extreme position. Although the patterns of morphological variation are apparently continuous between the two taxa, subsp. *schottii* is relatively easily recognizable as a separate taxonomic unit with a somewhat arbitrary boundary. In the Baboquivari Mountains and in northern Sonora and Chihuahua, a number of difficultly placed intermediate specimens have been collected.

Zapoteca formosa subsp. *schottii* could be confused with subsp. *mollicula*, since they have leaflets of comparable size. However, subsp. *schottii* can be readily distinguished by the longer internodes and more elongate petioles and rachillae (Table 14). Further, although vestiture is highly variable in subsp. *mollicula*, most of its individuals have denser vestiture than do plants of subsp. *schottii*.

13. Zapoteca scutellifera (Benth.) H. Hern., comb. nov. *Calliandra scutellifera* Benth., J. Bot. (Hooker) 2: 139. 1840; Benth., London J. Bot. 3:98. 1844; Benth., Trans. Linn. Soc. London 30: 542. 1875; Benth. in C. Martius, Fl. Bras. 15(2): 112. 1876. *Feuilleea scutellifera* (Benth.) Kuntze, Revis. Gen. Pl. 189. 1891. TYPE: Brazil. Territory of Rondônia: Rio Madeira, Ribeirão, in siccis arenosis, May 1828, *Riedel 1334* (lectotype, K, here designated; isolectotypes, A, K, LE (3), NY—fragm., P, US).

Scandent shrubs; branchlets terete or subangulate, the surface costate under magnification, glabrous to finely puberulent, usually villous on the younger parts. Leaves glandular, the pinnae 2 3-

jugate; petioles terete with a conspicuous adaxial channel, 3.5 8 cm long, glabrous to sparsely villous, villous in the area of the channel; rachis 1 5 cm long; rachillae 5–7 cm long; glands close to the base of the petioles, at the points of insertion of the pinnae, and sometimes between the distal pairs of leaflets, scutelliform, the larger ones on the petioles to 2 mm diam., glabrous to puberulent abaxially; leaflets 6–11 pairs per pinna, oblong-obovate, falcate or subfalcate, oblique at the base, rounded to subacute at the apex, mucronate, the median ones 15–20 × 5–7 mm, the proximal ones smaller, membranous, glabrous, sometimes ciliate; primary and secondary leaflet veins conspicuous abaxially; stipules leafy, linear-triangular, to 4 mm long, glabrous to villous. Capitula axillary; peduncles solitary or fasciculate at distant nodes, glabrous to sparsely villous, ca. 6.5 cm long at anthesis. Flowers pentamerous; calyx cup-shaped, 1–1.5 mm long, finely ciliate, the teeth triangular, acute; corolla campanulate, 4–5 mm long, glabrous, the lobes lanceolate; filaments ca. 2.5 cm long, white in the basal half, pink at the distal half, the staminal tube ca. 1 mm long; ovary ca. 1 mm long, glabrous. Pods acute, rostrate, ca. 9 × 0.7 cm, thickly membranous, finely puberulent, especially at the margins.

Distribution (Fig. 44). Endemic to the Amazon Basin where it has been collected at scattered localities. In Brazil known from the states of Amazonas and Pará, and from the territory of Rondônia, also in Bolivia from the departments of El Beni and Santa Cruz. It usually occurs in open sandy sites.

Additional specimens examined. BRAZIL: AMAZONAS: Amazonum ad ostium flum. Solimões, *Spruce 1586* (BM, G, F, GH, K, NY, P). PARÁ: Mun. de Itaituba, estrada Santarém–Cuiabá, BR 163. Km 1011 com uma penetracão de 3 km dentro da mata, margem direita do Rio Jamaxim sul do Pará, 70°40′S, 55°15′W, *Amaral et al. 1231* (MO, NY). BOLIVIA. EL BENI: prov. Vaca Diez, Guayaramerin, 10°49′S, 65°22′W, *Krapovickas & Schinini 35129* (MO). SANTA CRUZ: prov. Sará, Buenavista, 450 m, *Steinbach 7047* (A, BM, F, G, GH, K, NY, MO).

This morphologically uniform species is closely related to *Z. formosa* but differs by having scutelliform extrafloral glands, scandent habit, and usually smaller, linear-triangular stipules. Moreover, it can be distinguished from *Z. formosa* subsp. *formosa* by its white/pink, rather than white, filaments. The scutelliform glands, which are constant throughout the known populations of *Z. scutellifera*, are an excellent diagnostic feature, as they occur only in this species of *Zapoteca*. They are fully developed at the earliest stages of leaf development, which probably reflects their defensive function.

14. Zapoteca tehuana H. Hern., sp. nov. TYPE: cultivated at MO, Jan. 1, 1986, *H. Hernández 950* (holotype, MEXU; isotype, MO). (Original source: Mexico. Oaxaca: Distr. Tehauntepec, El Manguito, SW El Limón, a 11.1 km SW de la entrada a Buenos Aires, 800 m, *R. Torres 1167* (MEXU)). Additional isotypes to be distributed. Figure 45.

Frutices, caulibus gracilibus. Pinnae (1)2(3)-jugae, foliolis 10–21-jugis in utraque pinna, oblongo-lanceolatis vel ovato-lanceolatis, membranaceis vel sub-chartaceis, ordinatione venarum evidenter brochidodroma; stipulae foliosae ca. 2 mm longae. Numerus chromosomatum somaticus $2n = 26$.

Shrubs ca. 1 1.8 m high; stems slender, ca. 5 10 mm diam. at base, the bark smooth except for small exfoliations; branchlets terete, fissured under magnification, glabrous. Pinnae (1–)2(3)-jugate. Petioles eglandular, terete, with a conspicuous adaxial channel, 0.5 3 cm long, glabrous, sometimes sparsely villous; rachis 0.7 1.8 cm long in 2-jugate pinnae, to 3.8 cm long in 3-jugate pinnae; rachillae to 7 cm long; leaflets 10–21 pairs per pinna, oblong-lanceolate to ovate-lanceolate, the distal pairs sometimes obovate, at base oblique, at apex acute to subacute, sometimes mucronulate, the median ones 9–15 × 2 4 mm, the proximal and distal pairs smaller, the anterior proximal leaflet reduced in size, rarely lacking, all membranous to thinly chartaceous, usually drying light green, usually glabrous throughout, occasionally pilose and ciliate, with conspicuous brochidodromous venation; stipules leafy, triangular, ca. 2 mm long, glabrous, rarely pilose. Capitula axillary; peduncles fasciculate at distant nodes, filiform, (2–)7–10 cm long at anthesis. Flowers pentamerous, or rarely tetramerous; calyx ca. 2–2.5 mm long, glabrous or pilose, usually ciliate, each tooth with a central vein, triangular, ca. 1 mm long; corolla campanulate, ca. 5–5.5 mm long, glabrous, the lobes ovate-lanceolate, acute; filaments (20)24 25 mm long, white in the basal half and pink in the distal half or white throughout, the staminal tube ca. 2 mm long; ovary ca. 1.5 mm long, very shortly (< 0.3 mm) stipitate. Pods linear, at apex subacute, rostellate, to 12 cm long when mature, thickly membranous, glabrous, reticulate-veined. Seeds widely ovoid to widely rhomboid, flattened, 5 6 × 4 mm, gray, the areola light gray; pleurogram irregular, demarcated by a dark line. Somatic chromosome number $2n = 26$.

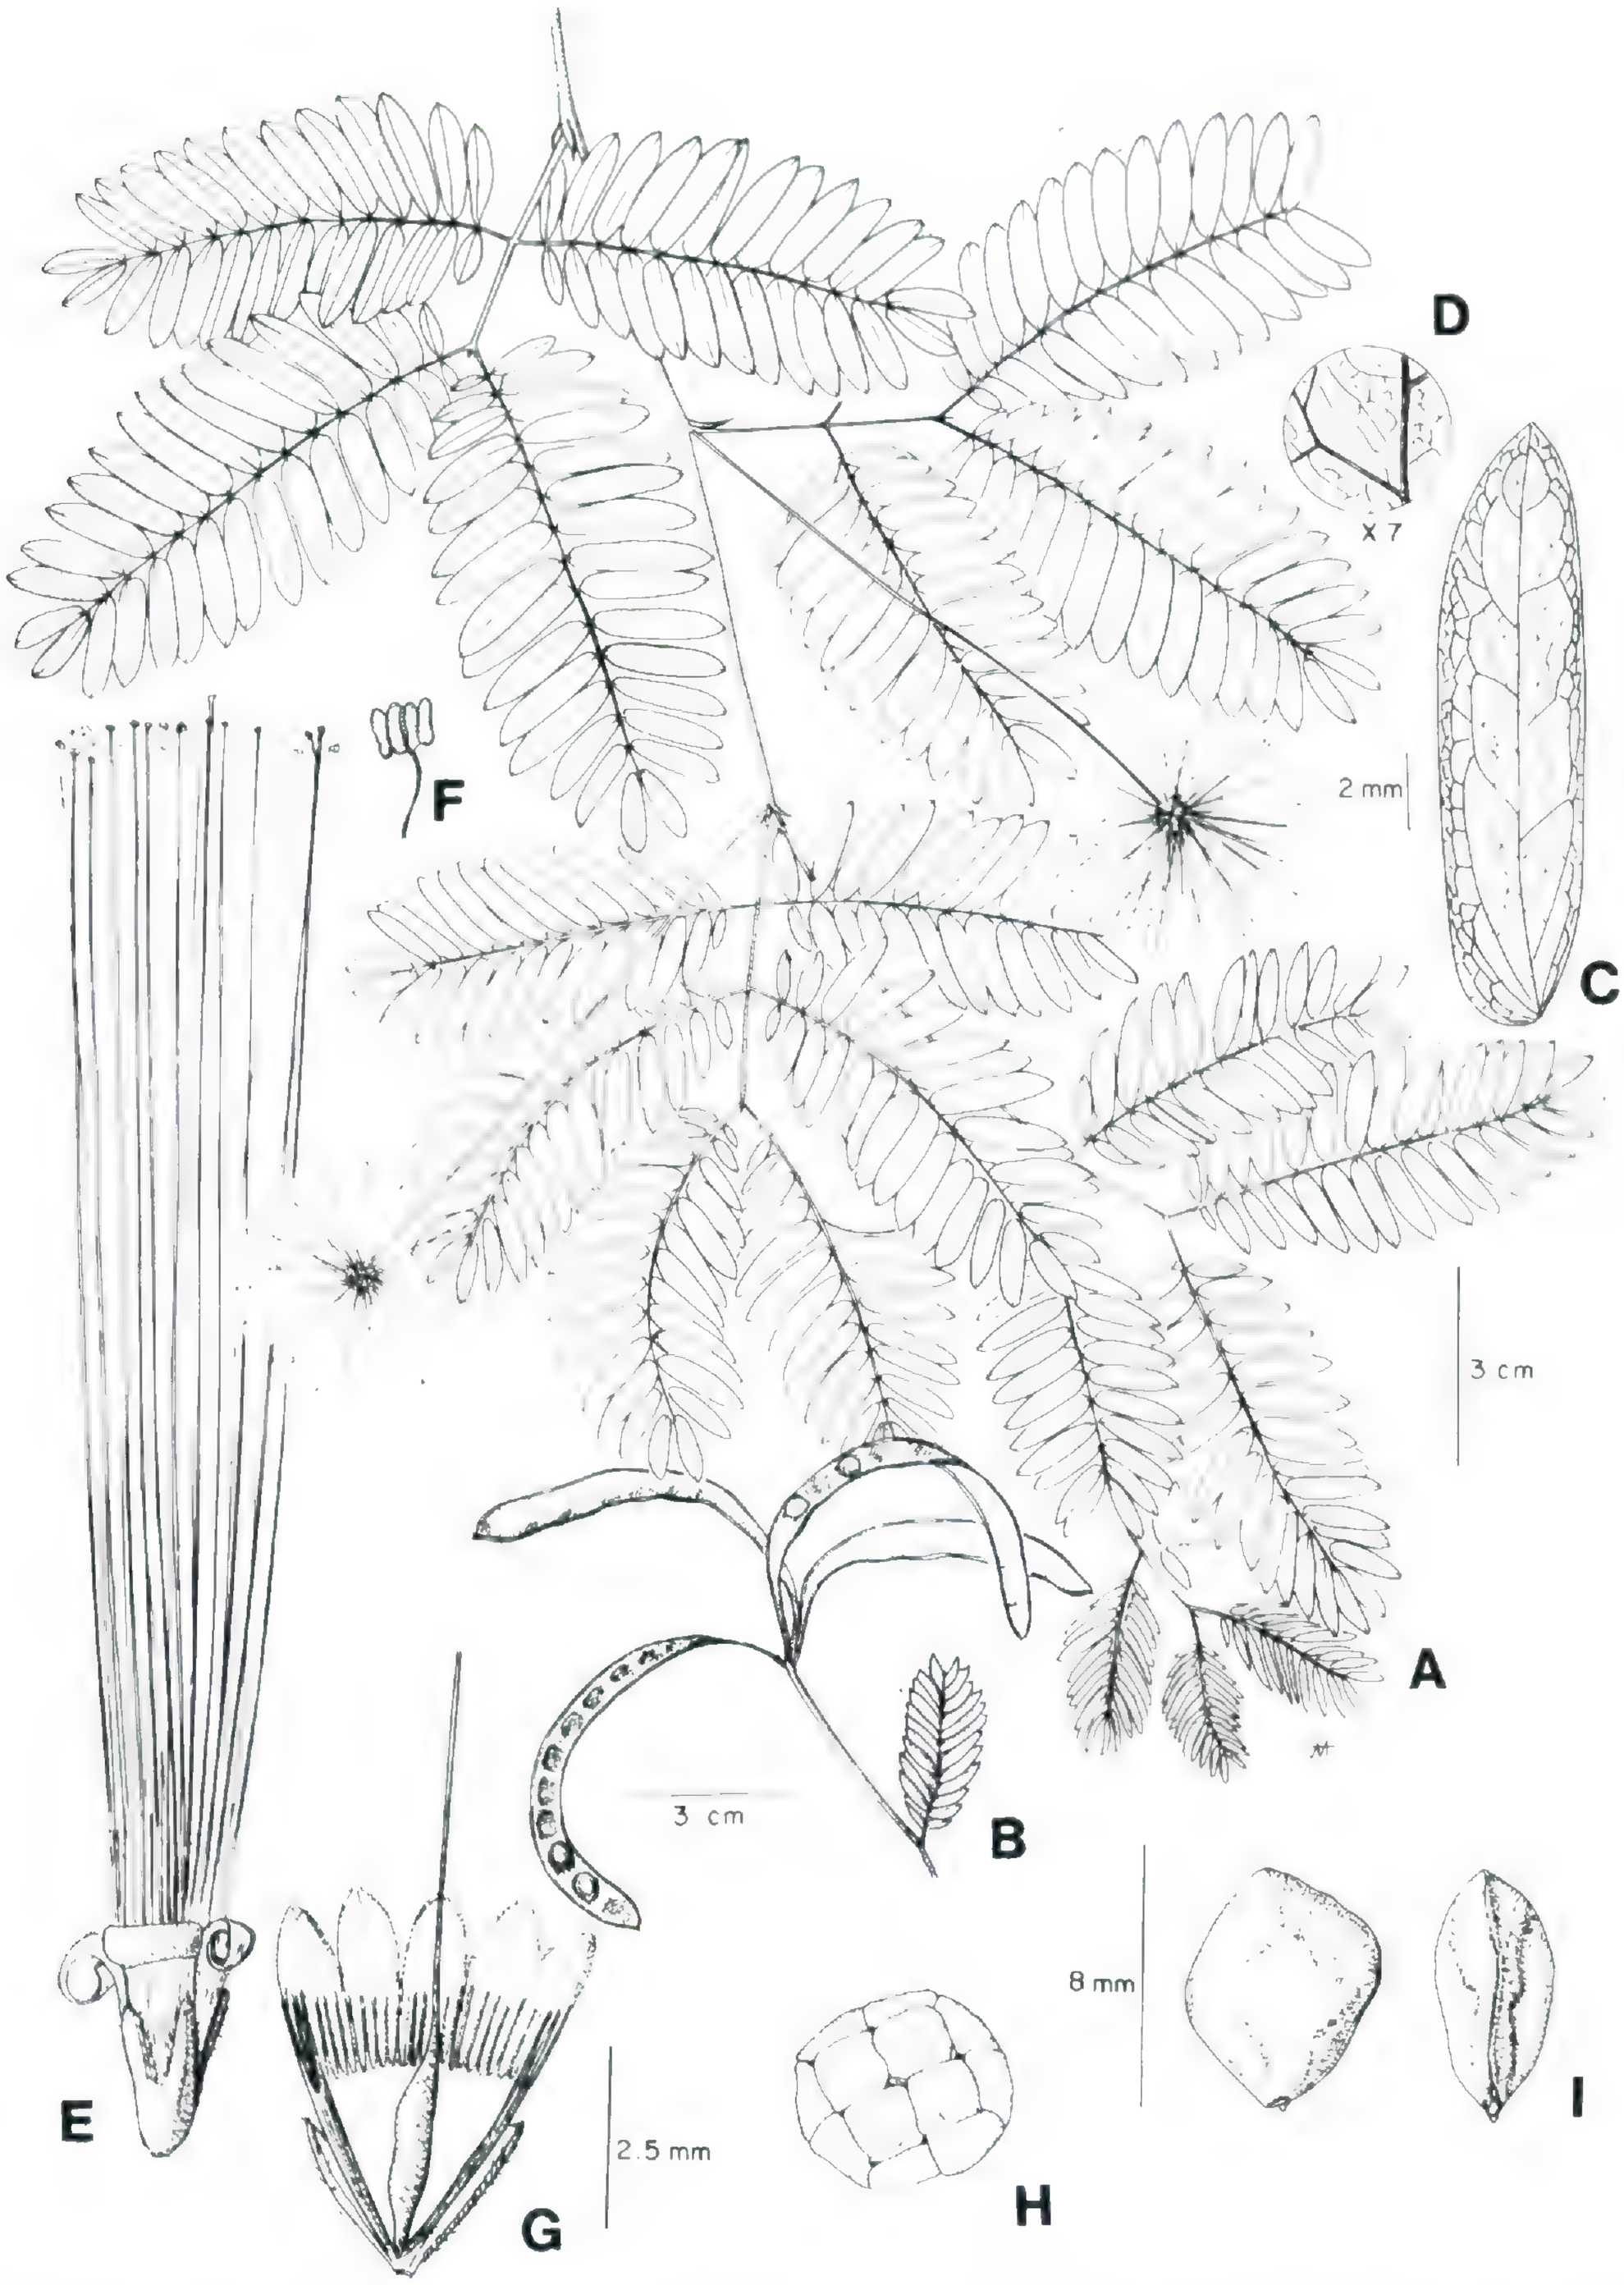

FIGURE 45. *Zapoteca tehuana.* A. Branchlet with inflorescences at anthesis. —B. Branchlet with dehisced pods. C. Leaflet. —D. Detail of venation in cleared leaflet. —E. Flower. —F. Anther. —G. Dissected flower. —H. Polyad. —I. Seeds. (Drawn from living plant, *H. Hernández 950* (MEXU, MO); pods from *R. Torres 4167* (MEXU).)

Distribution (Fig. 34). This species is endemic to a restricted area southwest of the Isthmus of Tehuantepec in Oaxaca, Mexico, where it grows in secondary vegetation derived from tropical deciduous forest mixed with probably relictual elements of temperate deciduous forests.

Additional specimens examined. MEXICO. OAXACA: Distr. Tehuantepec, cañada en el Arroyo de las Minas 2 km al SW de El Limón y 14 km al NW de Tehuantepec, *García & Torres 1679* (MEXU, MO); Distr. Tehuantepec, El Limón, arriba de El Chicozapote, SW de Tehuantepec, entrando por camino a Buenos Aires, *H. Hernández & Torres 303* (MEXU, MO); Distr. Tehuantepec,

El Manguito, al SW de El Limón el cual está a 11.1 km al SW de la entrada a Buenos Aires, *Torres 4167* (MEXU, MO); Distr. Tehuantepec, 15 km SW de Buenos Aires hacia Tenango, entrando por Hierba Santa, *Torres & Martínez 7375* (MEXU); subida al Cerro Guingola por ladera S, *L. Torres et al. 708* (MEXU).

Zapoteca tehuana is a narrowly endemic species probably not closely related to species of subg. *Zapoteca*, and further knowledge on this species could provide evidence for its placement in a separate subgenus. It differs from the remaining species of subg. *Zapoteca* primarily by having conspicuous brochidodromous leaflet venation and relatively thick leaflets. It might be confused with some of the species with oblong or ovate-lanceolate leaflets of comparable size (e.g., *Z. portoricensis* and *Z. lambertiana*) but differs by having leaves usually having fewer pairs of pinnae, smaller stipules, white or white/pink filaments, and shorter stature. The relationship between *Z. tehuana* and *Z. aculeata* are discussed under the latter.

III. Zapoteca subg. **Aculeata** H. Hern., subg. nov. TYPE: *Zapoteca aculeata* (Spruce ex Benth.) H. Hern.

Pinnae 1-, raro 2-jugae, folia sine nectariis, glabra vel fere glabra, foliolis 3–7-jugis in utraque pinna, mediocribus chartaceis vel coriaceis, ordinatione venarum conspicua; stipulae spinescentes. Capitula axillaria. Pollinia tumoribus lenticularibus praedita. Legumina coriacea glabra.

Leaves glabrous or nearly so, the pinnae 1-, rarely 2-jugate, the petiole without nectaries, leaflets 3–7 pairs per pinna, moderately large, chartaceous to coriaceous, with a very conspicuous venation; stipules spinescent. Capitula axillary. Polyads with lens-shaped thickenings. Pods coriaceous, glabrous.

This subgenus comprises a single species, *Z. aculeata*, characterized by medium size, chartaceous to coriaceous leaflets, and spinescent stipules.

15. Zapoteca aculeata (Spruce ex Benth.) H. Hern., comb. nov. *Calliandra aculeata* Spruce ex Benth., Trans. Linn. Soc. London 30: 541. 1875. TYPE: Ecuador, ad pedes m. Tungurahua, Sep. 1857, *Spruce 5054* (lectotype, K, here designated; isolectotypes, BM, F, G, (2), GH, K (2), LE, NY, P, S, (2)). The isolectotypes are dated as follows: BM, 1857–9; F, 1857–9; G, 1857–9, 1861; GH, 1857–9; K, Aug. 1857; LE, 1857–9; NY, 1857–9; P, 1857–9, 1861; S, 1857–9. Figure 46.

Trees to ca. 10 m tall; branchlets terete, costate, glabrous. Pinnae 1-, rarely 2-jugate; petioles eglandular, terete, with a conspicuous adaxial channel, 4–25 mm long, villous, rarely glabrate; rachis 3–5 cm long when pinnae 2-jugate; rachillae 1–12.5 cm long; leaflets (3–)4–6(–7) pairs per pinna, the proximal anterior one usually reduced or lacking, all ovate-lanceolate, at base oblique, at apex acute to acuminate, the distal ones 1.5–6.3 × 0.4–2.3 cm, the proximal ones smaller, all chartaceous to coriaceous, glabrous, the base sometimes villous; leaflet venation conspicuous; stipules spinescent, rigid, adpressed to the branchlets, sometimes becoming divaricate, linear-lanceolate, sometimes conical, beaked, 2–10 mm long, glabrous. Capitula axillary; peduncles usually fasciculate at distant nodes, rarely solitary, (2.5–)5–9 cm long at anthesis. Calyx shortly, sometimes irregularly dentate, ca. 2.5 mm long, glabrous, the teeth sometimes more than 5, shallowly triangular to deltate; corolla campanulate, 5–6 mm long, glabrous, the lobes ovate-lanceolate, acute; filaments ca. 2.5 cm long, red-purple, the staminal tube ca. 2 mm long; ovary ca. 1–1.5 mm long, glabrous. Pods about 10–12.5 × 0.9–1.1 cm, subacute to rounded at apex, sometimes rostellate, coriaceous, glabrous, the surface reticulate-veined.

Distribution (Fig. 47). *Zapoteca aculeata* has been collected from natural populations at the foot of the Mount Tungurahua in the Ecuadorian Andes (Province of Ambato) and from cultivated individuals at public gardens in Ambato, Baños, and Quito. Collections come from elevations of 1,900–2,850 m.

Additional specimens examined. ECUADOR. TUNGURAHUA: mountain side to S of Baños, *Penland & Summers 104* (F, GH, US). CULTIVATED. ECUADOR. PICHINCHA: Quito, *Acosta Solís 13599* (F). TUNGURAHUA: Ambato, *Acosta Solís 9488, 9523* (F); *Rose & Rose 22365* (GH, NY, US).

Zapoteca aculeata represents by itself a subgenus of *Zaboteca*. It is a poorly known, unmistakable species characterized by spinescent stipules, medium size, and coriaceous, ovate-lanceolate leaflets, which are usually larger than the essentially membranous leaflets of subg. *Zapoteca*. It is not obviously closely related to any other species of the genus; however, as shown in the chapter on morphology, an analysis of its leaflet architecture revealed outstanding similarities to that of *Z. tehuana*. *Zapoteca aculeata* is known from only a few collections made in a restricted area of the Ecuadorian Andes and from cultivated individuals

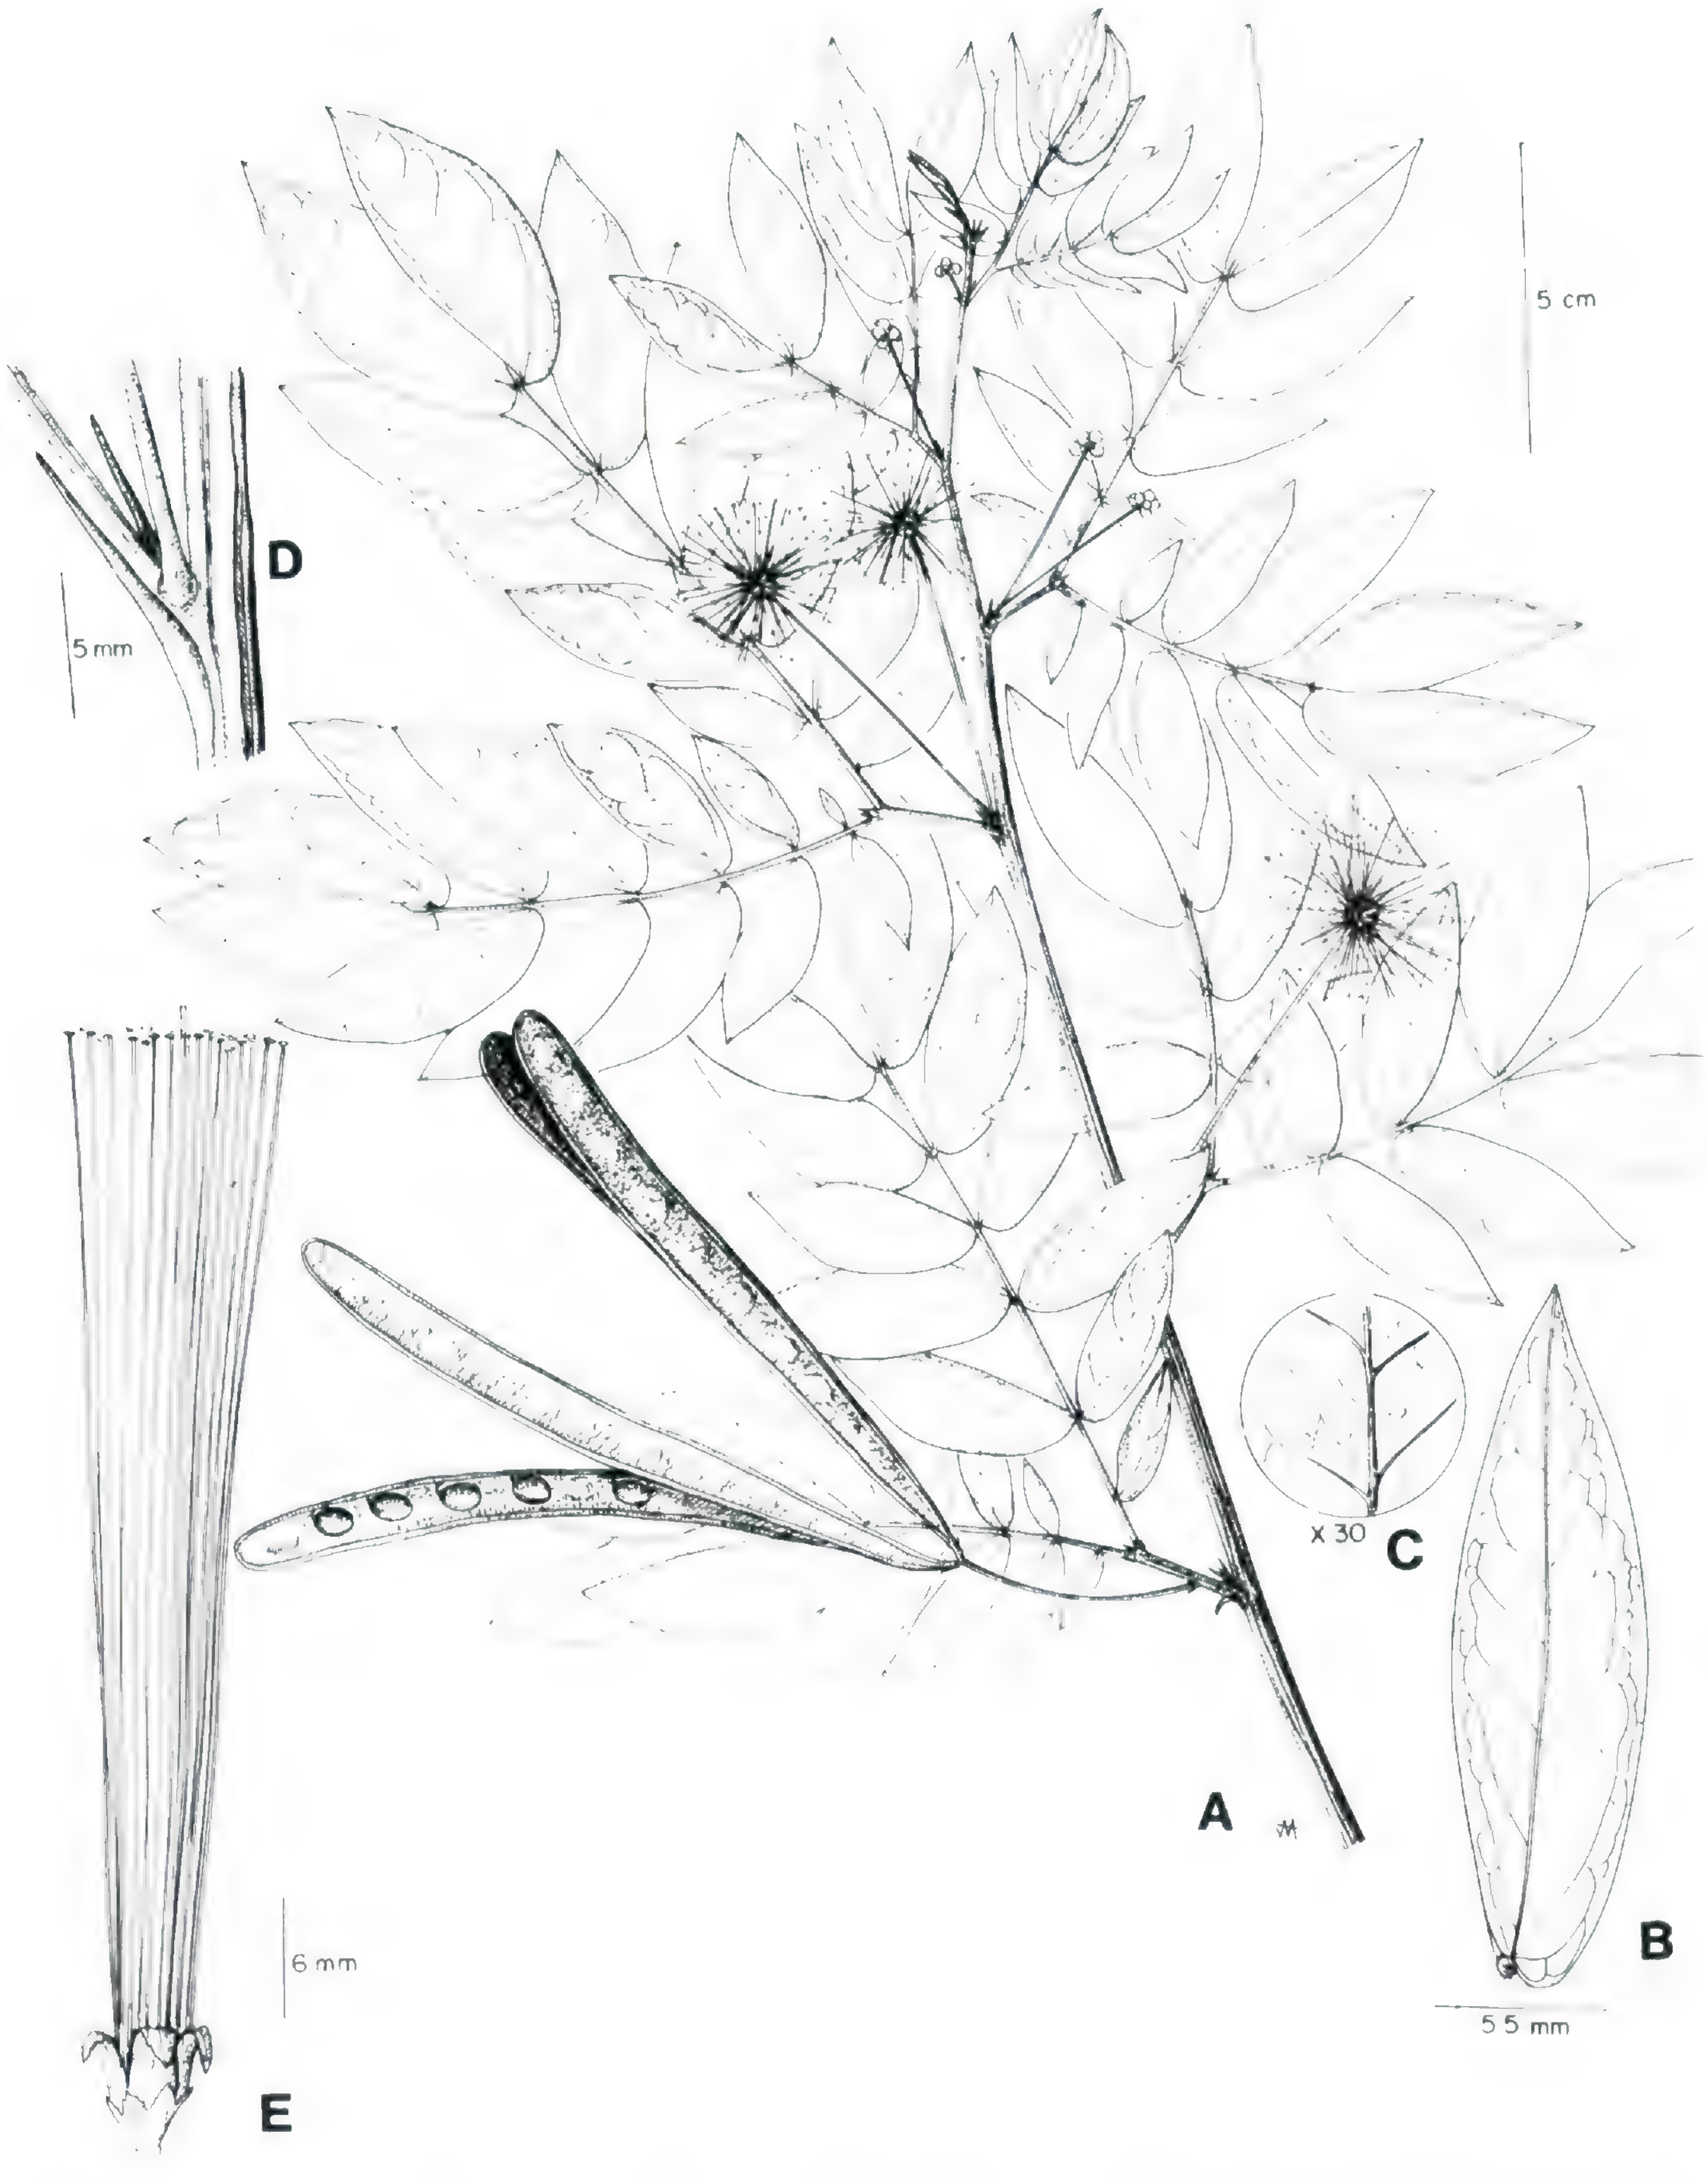

FIGURE 46. *Zapoteca aculeata.* – A. Branchlet with inflorescences at anthesis, and dehisced pods. — B. Leaflet. C. Detail of venation in cleared leaflet. D. Spinescent stipules. E. Flower. (From *Rose & Rose 22365* (US); leaflet from *Acosta 13599* (MO); pods from *Penland & Summers 104* (US).)

at Ambato, Baños, and Quito; it has not been collected for more than 40 years.

IV. Zapoteca subg. **Amazonica** H. Hern., subg. nov. TYPE: *Zapoteca amazonica* (Benth.) H. Hern.

Folia sine nectariis, glabra vel fere glabra, pinnis unijugis, foliolis 1 1½-jugis in utraque pinna, chartaceis vel coriaceis, ordinatione venarum forte conspicua; stipulae foliosae. Capitula in pseudopaniculis elongatis simplicibus vel compositis disposita. Pollinia tumoribus lenticularibus praedita. Legumina coriacea glabra. Semina sine pleurogramate.

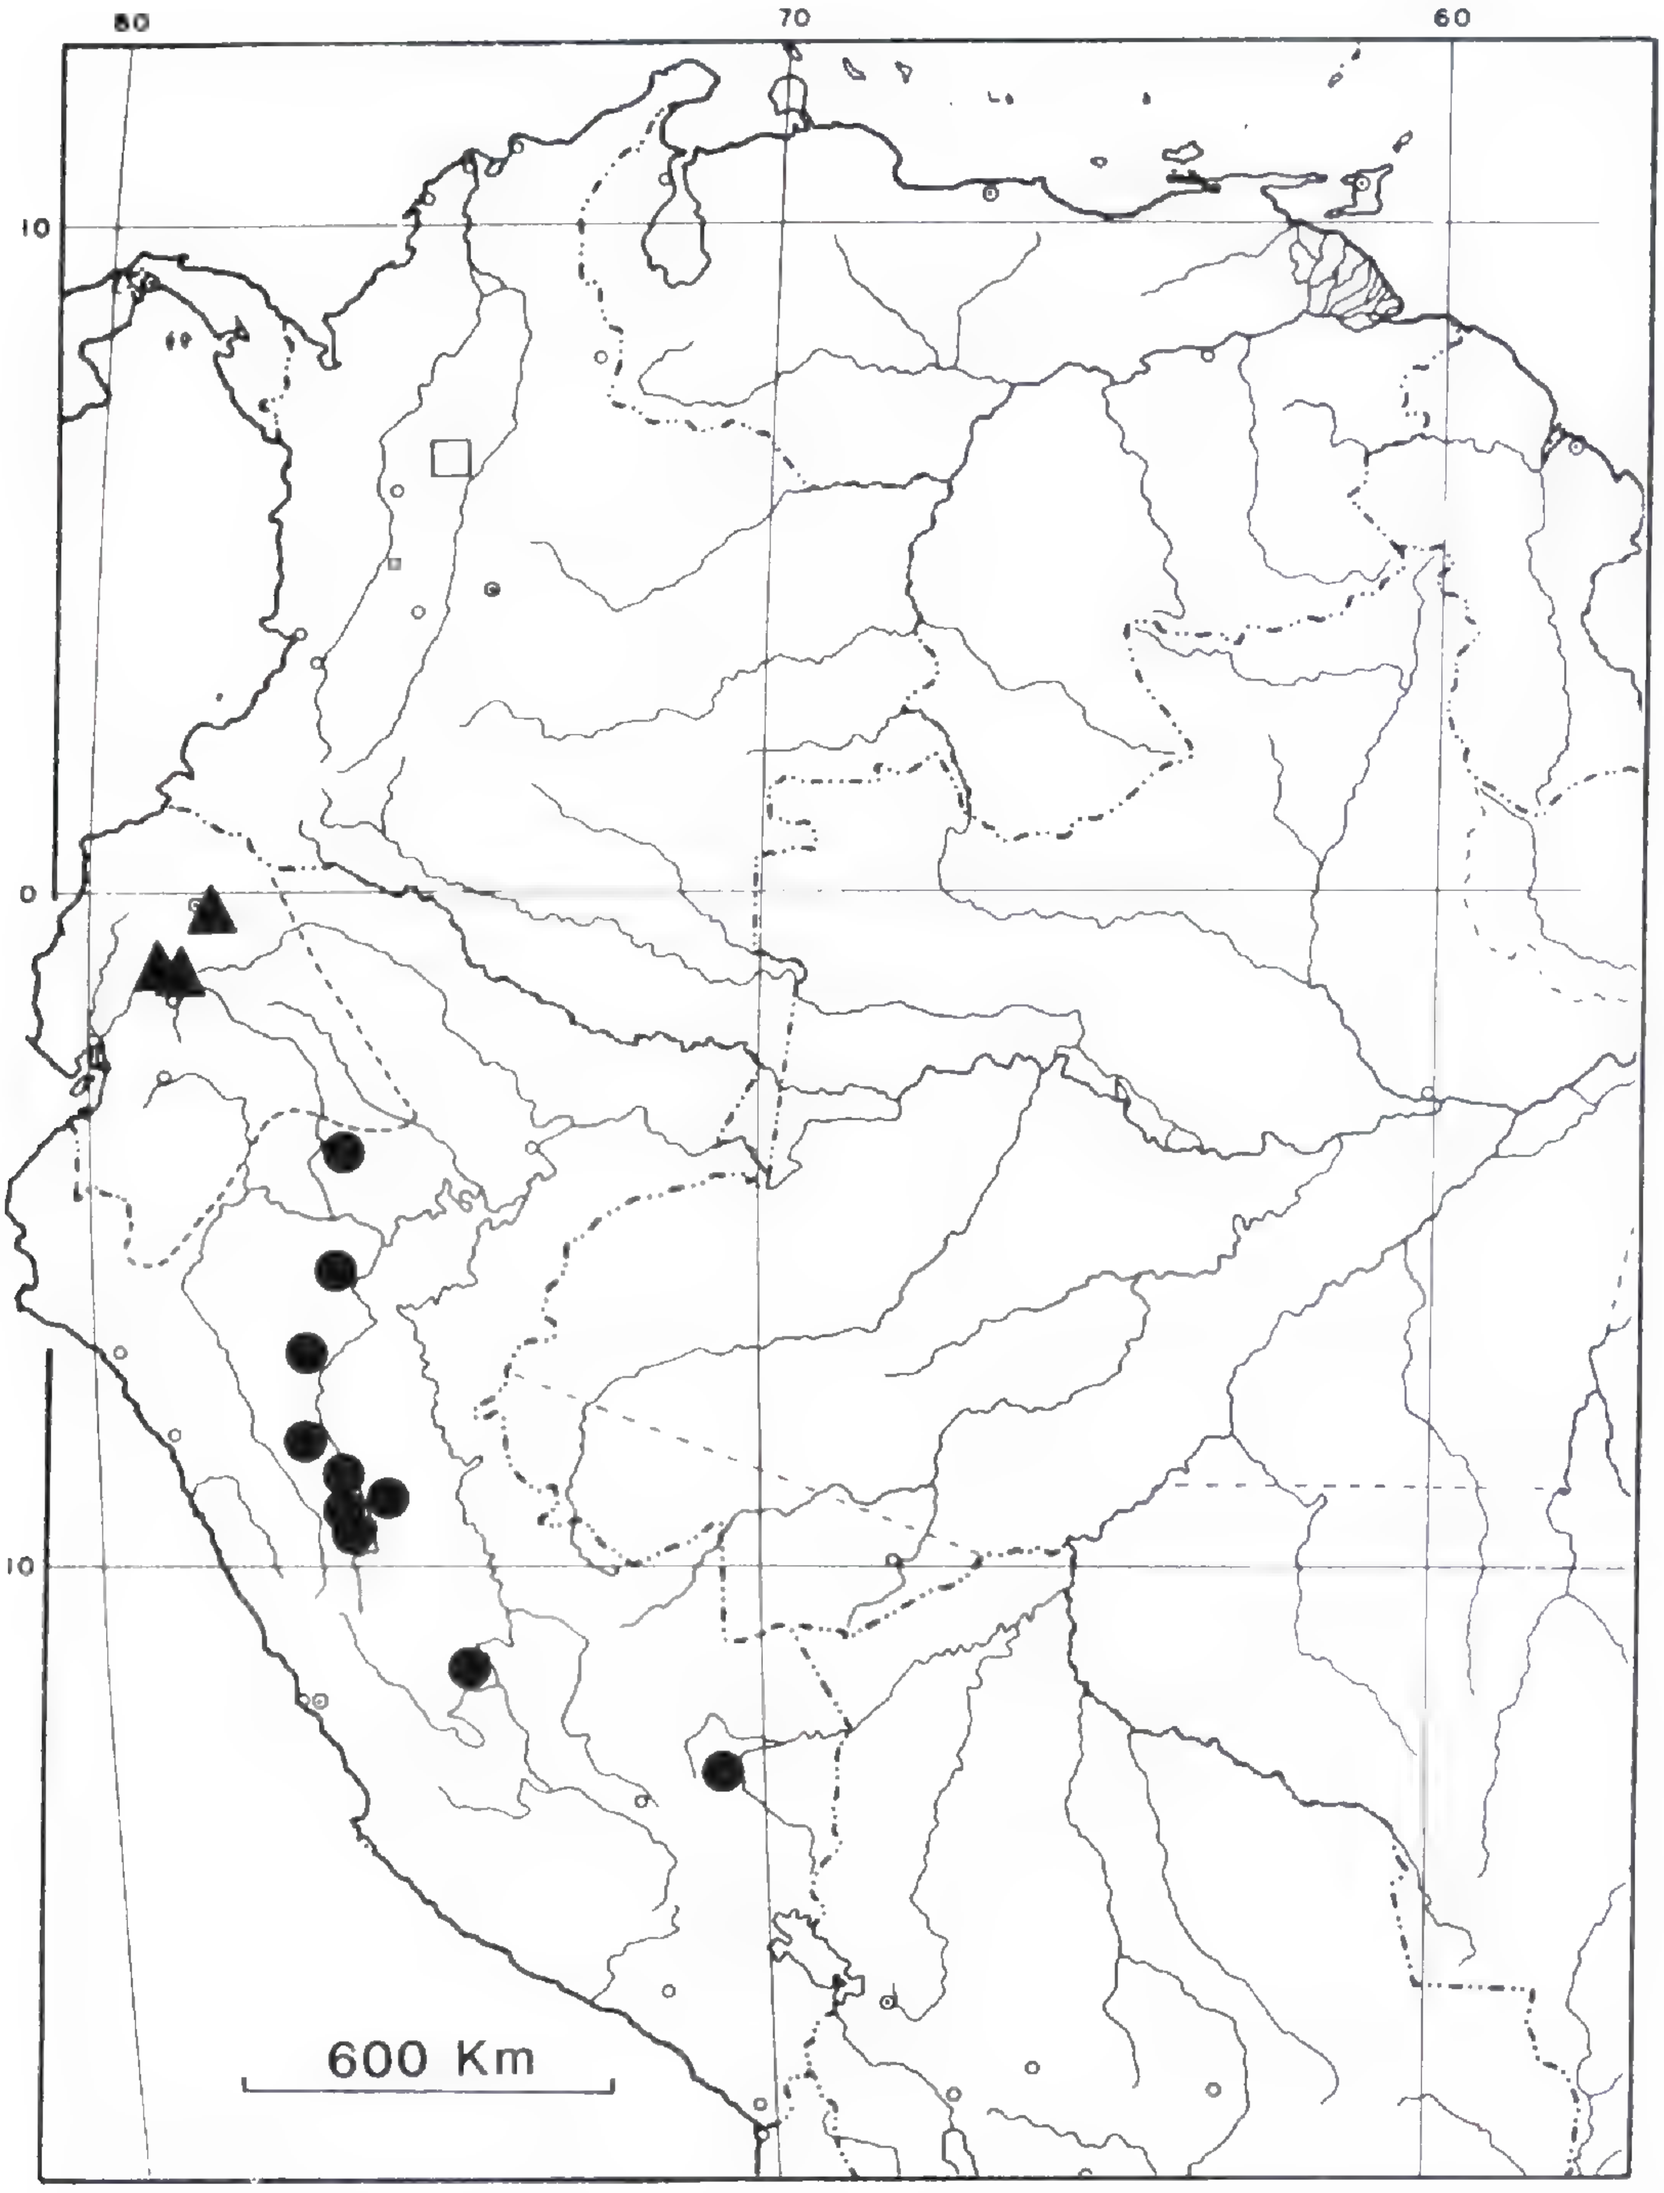

FIGURE 47. Distribution of *Zapoteca aculeata* (triangles), *Z. microcephala* (open square), and *Z. amazonica* (dots).

Leaves without nectaries, glabrous or nearly so, the pinnae 1-jugate; leaflets 1–1½ pairs per pinna, chartaceous to coriaceous; leaflet venation conspicuous; stipules leafy. Capitula in long, simple or compound pseudopanicles. Polyads with lens-shaped thickenings. Pods coriaceous, glabrous. Seeds without pleurogram.

This subgenus comprises two relatively specialized species, *Z. microcephala* and *Z. amazonica*, which are characterized by a set of characteristics that are highly advanced in *Zapoteca*: leaves reduced to one pair of pinnae, with 1–1½ pairs of large, chartaceous to coriaceous leaflets; capitula organized in long, simple or compound pseudopanicles.

16. Zapoteca microcephala (Britton & Killip) H. Hern., comb. nov. *Calliandra microcephala* Britton & Killip, Ann. New York Acad. Sci. 35: 134. 1936. TYPE: Colombia: 1760–1808, *Mutis 107* (holotype, US no. 1561096; isotypes, MA (4) not seen; photos at MEXU, MO).

Shrubs: branches terete, the surface smooth, glabrous. Pinnae 1-jugate; petioles eglandular, slender, with a pair of channels running longitudinally in the adaxial surface, (30–)40–70 mm long, glabrous abaxially, usually scabrous between the channels; rachillae 13–19 mm long; leaflets 1½ pairs per pinna, the proximal anterior leaflet lacking, all falcately lanceolate, at base strongly

TABLE 15. Comparison of *Zapoteca microcephala* with *Z. amazonica*.

	Z. microcephala	*Z. amazonica*
Distribution	Magdalena River Valley, Colombia	Amazonian Peru
Habit	erect shrubs	scandent shrubs
Pairs of leaflets per pinna	1½	1
Petiole length	(30)40 70 mm	20–42 mm
Leaflet pubescence	ciliate	glabrous
Pseudopanicles		
Form	simple	compound
Length	20–30 cm	up to 40 cm
Stipule length	1 2 mm	7–22 mm
Filament color	white	white/red-purple

oblique, sharply long-acuminate at apex, the distal leaflets 7.5–10.5 × 2.5–4.5 cm, the proximal one smaller, all chartaceous, glabrous, usually ciliate; leaflet venation conspicuous, with 2 primary and at least 1 secondary veins prominent; stipules leafy, triangular to narrowly triangular, ca. 1–2 mm long, glabrous. Capitula in terminal, elongate, simple pseudopanicles, ca. 20 30 cm long; peduncles fasciculate, rarely solitary, filiform, ca. 4.5 cm long at anthesis. Calyx ca. 2 mm long, the teeth triangular, < 1 mm long; corolla campanulate, ca. 3–4 mm long, the lobes ovate-lanceolate; stamens white, the staminal tube ca. 2 mm long. Pods to 15 × 1.1 cm when mature, at apex acute or retuse, coriaceous, glabrous, the valves reticulate-veined.

Distribution (Fig. 47). Endemic to a restricted area of the Median Valley of the Magdalena River in Colombia.

Additional specimens examined. COLOMBIA. SANTANDER: vicinity of Puerto Berrio, between Cararé and Magdalena rivers, *Haught 1711* (F, K, US), *Haught 1734* (US); without locality, *Mutis 3800* (MA, US).

This narrowly endemic species is clearly allied to *Z. amazonica*, from which it is geographically isolated (Fig. 47). *Zapoteca microcephala* can be readily distinguished from that species by 1½ pairs of smaller leaflets per pinna, simple (nonramified), shorter pseudopanicles, smaller stipules, and white filaments. Table 15 provides an account of the main comparative characters distinguishing these closely related species. *Zapoteca microcephala* is known from only four collections, and has not been collected since Haught (*1711*, *1734*) found it in 1935 in the floristically rich area of the Magdalena River Valley, Colombia.

17. Zapoteca amazonica (Benth.) H. Hern., comb. nov. *Calliandra amazonica* Benth., London J. Bot. 3: 94. 1844; Benth., London J. Bot. 5: 101. 1846; Benth., Trans. Linn. Soc. London 30: 538. 1875; J. F. Macbr., Fieldiana, Bot. 13: 67. 1943. *Inga bauhiniifolia* "*bauhiniaefolia*" Poeppig, Nov. Gen. Sp. Pl. 3: 80, t. 290. 1845. (The epithet is presumably also based on *Poeppig 2070* used by Bentham in the description of *Calliandra amazonica*.) TYPE of *Z. amazonica*: Peru. Loreto: in sylvis provinciae Maynas circum Yurimaguas, 1834, *Poeppig 2070* (lectotype, G, here designated; isolectotypes, F, G, LE pro parte, NY, P). The specimens at G and P are dated 1834, whereas those at F and NY are dated 1831. Figure 48.

Scandent shrubs 3–5(–8) m tall; stems slender, ca. 15 mm diam., the bark smooth; branchlets spreading, terete, glabrous. Pinnae 1-jugate; petioles eglandular, 20–42 mm long, usually glabrous; rachilla ± corrugate, with a conspicuous adaxial channel, 10–21 mm long (excluding the pulvini), usually glabrous, but occasionally sparsely villous in the extremes; leaflets 1 pair per pinna, falcately lanceolate-ovate, 7–22 × 2.8–9.2 cm, strongly oblique basally, acuminate to caudate, chartaceous to coriaceous, usually drying lighter green abaxially, ± lustrous adaxially, glabrous or rarely glabrate; leaflet venation conspicuous, with 2 primary and at least 1 secondary vein prominent; stipules leafy, ovate-lanceolate, acuminate to acute at apex, 7–22 × 3–8 mm, glabrous. Capitula arranged in terminal, elongate, compound pseudopanicles to 40 cm long or more, the peduncles fasciculate, rarely solitary, 0.8–7 cm long at anthesis. Calyx dentate, ca. 2.2 mm long, the teeth shallowly triangular or deltate, ca. 0.7 mm long, glabrous, rarely ciliate; corolla campanulate, ca. 4–5 mm long, glabrous, the lobes lanceolate; filaments white in the basal half and purple-red in the distal half, the tube ca. 2.5 mm long; ovary about 2 mm long, glabrous.

FIGURE 48. *Zapoteca amazonica*. A. Branchlet with compound pseudopanicle.—B. Primary stem showing smooth bark. C. Leaflet.—D. Detail of venation in a cleared leaflet. –E. Flower.—F. Pod.—G. Seed. (From *Plowman & Schunke 1115* (F) and *Schunke 1197* (G); stem from *Schunke 3371* (US); seed from *Schunke 1737* (US).)

Pods to 24 × 1 cm when mature, acute at apex, coriaceous, glabrous, the valves reticulate-veined. Seeds narrowly rhomboid to narrowly ellipsoid, flattened, ca. 14 × 5 mm, dark brown, without pleurogram.

Distribution (Fig. 47). This species has been collected primarily in shady sites of undisturbed tropical lowland forests of Amazonian Peru, from Río Alto Madre de Dios to Coronel Portillo (Río Pastaza) in the Departamento of Loreto, especially

along Río Huallaga. Collections come from 350–900 m.

Additional specimens examined. PERU. JUNÍN: Sanibeni ad Satipo, *Woytkowski 5943* (F, GH, LL, MO, NY, US). HUÁNUCO: above Río Huallaga at Tingo María, *Croat 21102* (MO); Tingo María, km 138, trocha lote del Aguila, *Ferreyra 932* (US); Pachitea, Puerto Inca, just N of town (9°18′S, 74°58′W), *Foster 8832* (MO); Pachitea, Codo de Pozuzo (9°40′S, 75°28′W), *Foster 9209* (MO); along Río Huallaga, near riachuela Chontalagua, *Mexia 8295* (BM, F, G, GH, MO, NY, S, UC, US); Leoncio Prado, Rupa Rupa, Tingo María (9°18′S, 75°59′W), *Plowman et al. 11249* (F, US); Tingo María, *Stork & Horton 9477* (F, G, UC). LORETO: Coronel Portillo, 4–5 horas arriba del caserío Abujao, sobre al Río Abujao, *Díaz 861* (MO, NY). MADRE DE DIOS: Pantiacolla, serranía across Río Alto Madre de Dios from Shintuya, *Gentry et al. 27293* (MO). SAN MARTÍN: Mariscal Cáceres, Tocache Nuevo, Cerro Sinsin, 15 km W Tocache Nuevo along road to Puerto Pizana (8°09′S, 76°34′W), *Plowman & Schunke 11445* (F); Mariscal Cáceres, Depto. Tocache, 2 km de Tocache Nuevo, Fundo la Campiña, *Schunke 3371* (F, G, NY, US); Mariscal Cáceres, Depto. Tocache Nuevo, Canato, margen izquierdo Río Huallaga, *Schunke 4497* (F, G, NY, US); Mariscal Cáceres, Depto. Tocache Nuevo, Malpaso de Balsa, Probana, 1 km abajo desembocadura Río Mishollo, *Schunke 4737* (F, GH, MO, US); Mariscal Cáceres, Depto. Tocache Nuevo, Quebrada de Santiago, E Puerto Pizana, *Schunke 6483* (MO, NY); Mariscal Cáceres, Puerto Pizana (margen derecho del Río Huallaga), *Schunke 6913* (MO); Mariscal Cáceres, Depto. Tocache Nuevo, Quebrada de Huaquisha (margen Río Huallaga), *Schunke 8053* (MO, NY); Tarapoto, *Spruce 4494* (BM, BR, F, G, GH, K, P, NY); Alto Río Huallaga, Tarapoto, *Williams 6548* (F, US).

Zapoteca amazonica and *Z. microcephala* represent a distinct evolutionary line within the genus; these closely related species probably differentiated from a common ancestor after becoming separated from the rest of the genus. *Zapoteca amazonica*, which is remarkably uniform morphologically, can be readily distinguished from *Z. microcephala* by its scandent habit, one pair of larger leaflets per pinna, larger stipules, elongate pseudopanicles, and white/purple-red filaments. The differences between the two species were discussed further under *Z. microcephala* (see also Table 15).

Zapoteca amazonica probably is the most specialized species in the genus, presenting a combination of derived characters: scandent habit; extreme reduction of leaflet number concomitant with an increase in size; relatively complex leaflet venation patterns; capitula organized in complex, terminal, compound pseudopanicles. The specialized nature of this species was discussed in the section on morphology.

POLLEN MORPHOLOGY OF THE MELANTHIACEAE AND ITS SYSTEMATIC IMPLICATIONS[1]

Masamichi Takahashi[2] *and Shoichi Kawano*[3]

ABSTRACT

Pollen grains of several selected genera of Melanthiaceae were observed with scanning and transmission electron microscopes. *Helonias* and *Ypsilandra* have the distinctive feature of the exine composed of an amorphous layer and spinules, which agrees well with *Heloniopsis*. *Chionographis* and *Chamaelirium* both have distinctive four-porate pollen grains with clavate exines. *Japonolirion*, endemic to Japan, has monosulcate grains with gemmate exines, clearly different from *Tofieldia*, which is characterized by disulcate grains with reticulate exines. *Aletris* shows a wide range of infrageneric variation in exine sculpture, perforate-foveolate, reticulate, and gemmate. *Xerophyllum* and *Narthecium* have monosulcate grains with reticulate exines; the two genera are distinguished by the size of the muri. Pollen of *Metanarthecium* has distinctive reticulate exine sculpture characterized by verrucate protrusions within lumina. The palynological data indicate that the Melanthiaceae consist of at least three heterogenous groups, among which *Helonias*, *Heloniopsis*, and *Ypsilandra* represent one group, and *Chamaelirium* and *Chionographis* another distinct group.

The Melanthiaceae comprise ca. 24 genera distributed in North America, Japan, and China (Dahlgren & Clifford, 1982). These genera are *Aletris*, *Amianthium*, *Chamaelirium*, *Chionographis*, *Helonias*, *Heloniopsis*, *Metanarthecium*, *Narthecium*, *Nietneria*, *Oceanoros*, *Petrosavia*, *Pleea*, *Protolirion*, *Schoenocaulon* (= *Sabadilla*), *Stenanthella*, *Stenanthium*, *Tofieldia*, *Toxicoscordion*, *Tracyanthus*, *Veratrum*, *Ypsilandra*, *Xerophyllum*, and *Zigadenus* (Dahlgren & Clifford, 1982). Krause (1930) recognized the tribe Tofieldieae (Liliaceae Melanthioideae), in which *Tofieldia* (Temperate-Arctic Northern Hemisphere), *Pleea* (eastern North America), *Narthecium* (Northern Hemisphere), and *Nietneria* (Guinea) were included. However, in his treatment, *Aletris* was placed in the different subfamily, Alectroideae. Hutchinson (1934, 1959) grouped these genera into two tribes, Heloniadeae and Narthecieae. The Heloniadeae, characterized by the absence of bracts, consist of *Helonias*, *Chamaelirium*, *Ypsilandra*, and *Chionographis*, and the tribe Narthecieae, characterized by the presence of bracts, comprise *Pleea*, *Tofieldia*, *Hewardia*, *Xerophyllum*, *Heloniopsis*, *Clara*, *Narthecium*, *Metanarthecium*, *Aletris*, and *Nietneria*. Hutchinson (1934, 1959) regarded the Heloniadeae as the most primitive tribe in the Liliaceae, and that the tribe is closely related to the Narthecieae. Dahlgren et al. (1985) placed these genera in the family Melanthiaceae and recognized six tribes, Petrosavieae, Melanthieae, Narthecieae, Tofieldieae, Chionographideae, and Xerophylleae. They included *Lophiola* in the tribe Narthecieae.

Although many brief notes on pollen morphology of these genera using light microscopy have been given by Beug (1961), Erdtman (1952), Faegri et al. (1964), Huang (1970, 1972), Huynh (1976), Ikuse (1956), Kuprianova (1948), Radurescu (1973), Schultze (1978), Shimakura (1973), Thanikaimoni (1970), Ting-Su (1949), Utech (1979), Wunderlich (1936), and Van der Hammen (1956), a comprehensive pollen morphological study has not been made for these genera with electron microscopy.

Although Schultze (1978) classified *Chionographis*, *Chamaelirium*, *Heloniopsis*, *Ypsilandra*, and *Helonias* in the tribe Heloniadeae, the different pollen types and exine structure suggest that the treatment is inappropriate. Recently, Tak-

[1] We express our gratitude to the directors and curators of the following herbaria for providing materials used in this study: U.S. National Arboretum (NA), Kunming Institute of Botany (KUN), and Tohoku University (TUS). We are also grateful to George Rogers, Missouri Botanical Garden, John D. Ambrose, University of Guelph, and Frederick H. Utech, Carnegie Museum of Natural History, for suggestions and comments on the study.

ahashi (1982a) showed that *Heloniopsis orientalis* Tanaka is characterized by a peculiar exine structure without columellae. He also pointed out that palynological evidence on the related genera would be useful to reveal their systematic relationships.

In the present study, pollen grains of 92 samples of 40 species of 15 genera in the Melanthiaceae were studied in detail with transmission and scanning electron microscopes. The probable systematic relationships of these genera are proposed based on the palynological evidence thus obtained.

MATERIALS AND METHODS

Pollen grains were taken from specimens in the herbaria of Carnegie Museum of Natural History (CM), U.S. National Arboretum (NA), Kunming Institute of Botany (KUN), Kyoto University (KYO), and Tohoku University (TUS). Voucher specimens are listed in Table 1. Pollen grains from each specimen were observed using scanning electron and transmission electron microscopy. Preparation methods followed Takahashi (1982b). An image analyzing system IBAS-1 was used for measurements and calculations of pollen grains.

OBSERVATIONS

Helonias and *Ypsilandra* (Figs. 1–4)

Pollen grains monosulcate, 27.7 ± 1.3–28.5 ± 1.6 μm in major axis of ellipse and 19.3 ± 2.2–20.0 ± 2.0 μm in polar axis of *Helonias bullata*, and 30.0 ± 1.8 in major axis of ellipse and 21.0 ± 2.3 in polar axis of *Ypsilandra yunnanensis*, provided with a sulcus. Except for sulcus, exine ornamentation finely granulated with spinules (Figs. 2, 3), these ovate, 1 μm high, with acute tips. Exine (spinules excluded) 0.4–0.6 μm thick, consisting of an amorphous layer and spinules. Outer surface of exine granular and the inner layer lamellated (Fig. 4).

There is no difference in pollen type and exine structure between *Helonias* and *Ypsilandra*.

Chamaelirium and *Chionographis* (Figs. 5 9)

Pollen grains spherical, 4-porate (Figs. 5, 8), 16.2 ± 1.2–19.0 ± 1.5 μm in major axis of ellipse and 16.0 ± 1.0 18.1 ± 1.3 μm in polar axis of *Chamaelirium*, and 13.2 ± 0.9–16.2 ± 1.2 in major axis of ellipse and 16.2 ± 1.8 μm in polar axis of *Chionographis*. Porus with exinous gemmae. Except for the porus, exine sculpture clavate. Clavae with small projections on the head (Fig. 7). Exine structure intectate, consisting of 0.4 0.5-μm-high clavae and 0.4 0.4-μm-thick foot layer. Inner part of foot layer lamellated.

There is no difference in pollen type and exine structure between *Chamaelirium* and *Chionographis*.

Tofieldia (Figs. 10–17)

Pollen grains disulcate, 16.7 ± 0.9–25.2 ± 2.1 μm in major axis of ellipse and 10.9 ± 0.8 18.9 ± 1.4 μm in polar axis. Pollen size variable among species. Furrows extending near the ends of pollen grains. Except for the furrows, exine ornamentation reticulate, consisting of 0.5-μm-thick muri and

Exine structure of *J. ozense*, TEM ×2,400.

lumina 0.2–0.7 μm diam. with nonangulate margins. Exine structure semitectate, consisting of 0.3-μm-thick tectum, 0.1-μm high columellae, and 0.2–0.3 μm-thick foot layer.

The reticuloid exine sculpture of *T. pusilla*, which has discontinuous muri, is unique in the genus.

Pleea

Pollen grains disulcate, 20.0 ± 1.5 22.7 ± 1.3 μm in major axis of ellipse and 15.8 ± 1.3–17.9 ± 1.2 μm in polar axis. Furrows extending near the ends of pollen grains. Except for the furrow, exine ornamentation reticulate, consisting of muri and lumina 0.2–0.3 μm diam. with nonangulate margins. Exine 0.5 μm high, consisting of 0.2-μm-thick tectum, 0.1-μm-high columellae, and 0.2-μm-thick foot layer.

Japonolirion (Figs. 18–20)

Pollen grains monosulcate, 19.2 ± 2.0 μm in major axis of ellipse and 15.6 ± 1.8 μm in polar axis, provided with a furrow. This with no marginal thickening, exinous islet absent. Except for the sulcus, exine ornamentation gemmate. Gemmae 0.2–0.3 μm diam., spheroidal. Exine composed of foot layer 0.2–0.3 μm thick and gemmate protrusion 0.3–0.4 μm high.

Xerophyllum (Figs. 21 24)

Pollen grains monosulcate, 22.6 ± 1.5–29.0 ± 3.2 μm in major axis of ellipse and 14.9 ± 1.4–19.9 ± 1.3 μm in polar axis, provided with a furrow, this lacking exinous islets. Except for the furrow, exine ornamentation reticulate and characterized by narrow muri, these 0.1–0.2 μm thick, the angulate lumina 0.5–1.0 μm diam. Exine 1.0 μm thick, semitectate, consisting of 0.5–0.6-μm-thick tectum, 1.0-μm-high columellae, and 0.5–0.6-μm-thick foot layer.

There is no conspicuous difference in pollen morphology between *X. asphodeloides* and *X. tenax*.

Varthecium (Figs. 25–27)

Pollen grains monosulcate, 17.7 ± 1.3–20.6 ± 1.5 μm in major axis of ellipse and 11.9 ± 1.2–13.5 ± 1.2 μm in polar axis, provided with a furrow. Exine 0.5 μm thick, semitectate, consisting of 0.2-μm-thick tectum, 0.2-μm-high columellae, and 0.1-μm-thick foot layer, reticulate, the reticulum consisting of 0.3-μm-thick muri and lumina 0.1–0.5 μm diam.

No conspicuous interspecific variation was recognized in pollen size, pollen type, and exine sculpture within *Varthecium*.

Aletris (Figs. 28 32)

Pollen grains monosulcate, 21.8 ± 1.5–32.4 ± 3.8 μm in major axis of ellipse and 14.0 ± 2.4–20.5 ± 3.2 μm in polar axis, provided with a sulcus with exinous gemmae. This extended to the ends of grains.

The genus shows wide variation in exine sculpture, e.g., perforate-foveolate, reticulate, and gemmate. The perforate-foveolate type is shown in *A. aurea*, *A. bracteata*, *A. farinosa*, *A. obovata*, and *A. lutea*. The perforatum are 0.1–0.3 μm in diameter.

The reticulate type is represented by *A. folia*, *A. spicata*, and *A. ossifragum*. Here the lumina, 0.5–1.0 μm in diameter, are roudish rather than angulate. The foveolate or reticulate exine consists of tectum, columellae, and foot layer.

The gemmate type is observed in *A. pauciflora* and *A. lanuginosa*. The gemmate exine is composed of 0.6–0.8-μm-gemmae and 0.2–0.3-μm-foot layer.

Metanarthecium (Fig. 33)

Pollen grains monosulcate, 17.2 ± 1.3 18.3 ± 1.0 μm in the longest axis of ellipse and 11.6 ± 1.5–13.5 ± 1.5 μm in polar axis, provided with a furrow having a membranous surface and no marginal thickening. Except for the furrow, exine sculpture reticulate, the reticulum characterized by small projection on lumina (Fig. 33). Lumina 1.0–1.5 μm diam., muri 0.2 0.3 μm thick. Exine composed of tectum, columellae, and foot layer.

Lophiola (Figs. 34 35)

Pollen grains monosulcate, 18.5 ± 1.6 μm in the longest axis of ellipse and 12.7 ± 1.8 μm in polar axis, provided with a furrow. Exine sculpture reticulate, the reticulum composed of 0.1–0.3-μm-wide lumina and 0.1-μm-thick muri.

Amianthium, *Stenanthium*, and *Schoenocaulon* (Figs. 36 39)

Pollen grains monosulcate, 23.2 ± 1.4 25.2 ± 1.6 μm in the longest axis of ellipse and 15.4 ± 1.2–17.2 ± 1.4 μm in polar axis, provided with

a furrow, the furrow with an operculum. Exine sculpture reticulate, the reticulum consisting of 0.3-μm-wide lumina and 0.3 0.6-μm-thick muri. The lumina angular.

DISCUSSION

Helonias and *Ypsilandra* are characterized by a distinctive exine structure that consists of an

amorphous layer and spinules, and the same exine structures were observed in *Heloniopsis* (Takahashi, 1982a). Utech (1978, 1980) and Utech & Kawano (1981) suggested that *Heloniopsis* and *Helonias* should be maintained in the same tribe based on floral vasculature and karyology despite Hutchinson's (1934, 1959) placement of *Helonias* in Heloniadeae apart from *Heloniopsis* in the Narthecieae. The present pollen morphological evidence supports the suggestion by Utech & Kawano (1981) and further indicates that *Ypsilandra* should be included in the same tribe with *Helonias* and *Heloniopsis*. The three genera are closely related to each other and are distinctive because of the amorphous exine structure with spinules. Dahlgren et al. (1985) included *Helonias* and *Heloniopsis* in the tribe Narthecieae, with *Methanarthecium*, *Vietneria*, *Narthecium*, and *Lophiola*. We now regard *Helonias*, *Heloniopsis*, and *Ypsilandra* as congeneric, and a more thorough taxonomic account of this controversial group is needed.

Chionographis from Japan has clavate exine sculpture and four-porate pollen grains. *Chamaelirium* from the eastern United States has the same pollen. This type of grain and exine structure are unique in the Melanthiaceae, and suggest that *Chamaelirium* and *Chionographis* are closely related to each other as an isolated group in the Melanthiaceae. The pollen morphology supports the treatment of Dahlgren et al. (1985), who distinguished the tribe Chionographideae as made up of *Chionographis* and *Chamaelirium*.

Japonolirion, which consists of only the Japanese endemic *J. ozense*, is sometimes included in *Tofieldia* (Willis, 1966; Hutchinson, 1934, 1959). The pollen grains of *Japonolirion* are monosulcate with gemmate exines, as opposed to those of *Tofieldia*, which are disulcate with reticulate exines. The pollen morphology of *Japonolirion* implies that the genus should not be included in *Tofieldia* but should be treated as a separate genus. The report of gemmate exine of *Tofieldia okuboi* (Ikuse, 1956) appears to be incorrect, as we have found reticulate exine in this species, conforming to other species of *Tofieldia*.

There is a wide range of variation in exine sculpture, perforate-foveolate, reticulate, and gemmate types in the genus *Aletris*. The species with gemmate exine are *A. lanuginosa* and *A. pauciflora*, which are distributed in China and Nepal. The other species of *Aletris* have reticulate exines. Similar variation in exine sculpture occurs in *Clintonia* (Takahashi & Sohma, 1982) and *Paris* (Takahashi, 1984). A parallel derivation from tectate-perforate to intectate exine appears to have taken place independently within these genera (Takahashi, 1984).

Ambrose (1985) transferred the genus *Lophiola* into the Narthecieae. The exine sculpture of the genus has a reticulum similar to that of genera in the Narthecieae; thus the palynological evidence supports Ambrose's taxonomic position of *Lophiola*. All the evidence available at present suggests that Heloniadeae and Narthecieae sensu Hutchinson (1959) consist of at least three or four heterogenous groups, and therefore the revision of the classificatory system of these groups is now in order.

A NEW SUBGENUS AND FIVE NEW SPECIES IN *PASSIFLORA* (PASSIFLORACEAE) FROM SOUTH AMERICA[1]

Linda K. Escobar[2]

ABSTRACT

Five new species of *Passiflora* (Passifloraceae) are described: *Passiflora solomonii* from Bolivia; *P. caatingae* from Bahia, Brazil; *P. sierrae* from the Sierra Nevada de Santa Marta of northeastern Colombia, and *P. amazonica* and *P. pascoënsis* from Peru. *Passiflora sierrae* is placed in a new subgenus *Porphyropathanthus*. All are lianas or herbaceous climbers with axillary tendrils and simple leaves, found on roadsides or in recent clearings.

Passiflora amazonica L. Escobar, sp. nov. TYPE: Peru. Amazonas: Bongara Prov., km 385–365 Moyobamba Bagua road (77°45′W, 5°45′S), 2,000 1,800 m, 17 Feb. 1984, *D. N. Smith 6012* (holotype, MO). Figure 1.

In subg. *Tacsonia* juxta *P. mixtam* Linn. f. collocanda, ab hac foliis rugosis rigide coriaceis margine grosse dentatis diversa.

Liana. Plants pubescent with straight to curling yellowish, transparent trichomes 0.2 1.0 mm long. Stems subangular, striate. Leaf blades 3-lobed to ca. ½ their length, widely depressed ovate in outline, (8.5 -)11–11.7 cm long, (9.0–)14–15.2 cm wide, acute at lobe apices, deeply cordate at base, coarsely dentate at margins, stiff-coriaceous, rugose, scarcely pubescent (mostly on veins) on adaxial surface, densely pubescent on abaxial surface with curved trichomes ca. 0.5 mm long; leaf lobes ovate, lateral ones (6.0–)7.2–8.2 cm long, (3.6–)4.2–5.6 cm wide, divergent from mid-lobe ca. 75°, this (7.3–)9.3–9.7 cm long, (4.2)5.4–5.8 cm wide; petioles 2.3 2.6 cm long, with up to 10 elongated nectaries ca. 1 mm long scattered along adaxial surface; stipules auricular, ca. 1.5 cm long, ca. 0.7 cm wide, acuminate with arista 4.6 mm long at apex, lacerate at margins. Peduncles solitary, 5–6 cm long; bracts 3, connate ca. ¼ their length, forming a closely fitting tube around base of hypanthium, each bract lanceolate, 3–4 cm long, ca. 1.4 cm wide, acuminate at apex, densely pubescent with tightly curled trichomes on inner surface, moderately pubescent with slightly curved trichomes on outer surface; flower stipe ca. 4 mm long. Flowers salverform, 9.5–10.5 cm long, ca. 6.5 cm diam. at apex, probably pendent; hypanthium cylindrical, ca. 6.5 cm long, 1.0 1.2 cm wide (pressed), densely pubescent on outer surface with straight to slightly curved trichomes up to 1 mm long; sepals ovate-oblong, 4.0–4.3 cm long, 1.2–1.8 cm wide, acute at apex with subapical arista ca. 1 mm long, coriaceous, pink; petals subequal to sepals, up to 1.5 cm wide, rounded at apex, membranaceous, pink; corona reduced to an undulate, irregularly toothed band; operculum dependent, nonplicate; ovary pubescent with straight trichomes ca. 0.5 mm long. Fruit unknown.

Distribution. *Passiflora amazonica* is known only from montane forest at 1,800–2,000 m elevation in Amazonas Department in northern Peru.

Additional collections examined. PERU. AMAZONAS: Bongara. 40 43 km E of Pomacocha, near La Cumbre, km 376 of Carretera Marginal, 5°45′S, 77°45′W, 13 June 1986, *S. Knapp & P. Alcorn 7740* (MO).

Passiflora amazonica is placed in subg. *Tacsonia* near *P. mixta* L. f., a widespread Andean species (Escobar, 1980; Killip, 1938) from which it differs by the stiff-coriaceous, rugose leaves with coarsely dentate margins.

[1] The present study was initiated in November 1987 while on a leave of absence, and completed in 1988 while on a sabbatical leave supported by the University of Antioquia. I am grateful to the curators of the herbaria of the Missouri Botanical Garden, The New York Botanical Garden, and the Smithsonian Institution for help and use of the facilities during my stay at their institutions. Special thanks are due Dr. Rupert Barneby, who reviewed the manuscript and provided the Latin diagnoses, and to Dr. John MacDougal for criticism of the manuscript.

FIGURE 2. Holotype of *Passiflora caatingae* L. Escobar, deposited in the herbarium of the Missouri Botanical Garden (MO).

Passiflora caatingae L. Escobar, sp. nov. TYPE: Brazil. Bahia: 27 km NE of Cândido Sales, along Highway BR-116, caatinga, 890 m, 30 Mar. 1976, *G. Davidse, T. P. Ramamoorthy & D. M. Vital 11635A* (holotype, MO). Figure 2.

Subgeneris *Tacsonioidi* referenda, *P. mendoncae* Harms proxime accedens, sed ab hac stipulis lineari-lanceolatis bracteisque minoribus diversa.

Liana. Plants glabrous with terete, striate stems. Leaf blades 3-lobed to ca. ¾ their length, depressed ovate in outline, 3.6–6.9 cm long, 6.4–11.2 cm wide, acuminate at lobe apices, cordate at base, shallowly serrate at margins (glandular in sinuses of serrations on very young leaves), coriaceous, lustrous, yellow-green; leaf lobes elliptic to oblong, lateral lobes 3.8–5.5 cm long, 1.5–2.2 cm wide, divergent from mid-lobe ca. 85°, mid-lobes 4.0–6.8 cm long, 1.6–2.8 cm wide; petioles 0.9–2.4 cm long, with 2–4, paired, scarlike nectaries at or below mid-point on adaxial surface; stipules linear-lanceolate, soon deciduous, ca. 1 mm long, ca. 0.2 mm wide at base. Peduncles solitary, 2.0–2.5 cm long; bracts 3, free to base, verticillate, ovate, 1.0–1.5 cm long, 0.8–1.0 cm wide, borne 0.5–1.1 cm below base of hypanthium, acuminate at apex, with arista ca. 0.5 mm long, narrowed at base, minutely serrate at margins; flower stipe 0.5–1.1 cm long. Flowers salverform 3.2–5.0 cm long, ca. 4 cm diam. at apex; hypanthium slightly funnel-shaped, 1.3–1.5 cm long, ca. 9 mm wide at apex, ca. 6 mm wide at base then inflated, with inflated portion 5 mm long, 1 cm wide; sepals oblong, 2.6–3.3 cm long, ca. 7 mm wide, with keel 2 3 mm wide on abaxial surface, subcoriaceous, red-purple; petals oblong, ca. 3.1 cm long, ca. 0.7 cm wide, rounded at apex, membranaceous, red-purple; corona in 2 series ca. 2 mm apart, filamentous, with inner series ca. 5 mm long, outer series ca. 2–3 mm long; operculum erect, nonplicate, ca. 4 mm long, lacerate at margin, transparent. Immature fruit ellipsoidal, 3.9–4.4 cm long, 2.0 2.9 cm wide (pressed).

Distribution. *Passiflora caatingae* is known only from two collections near Cândido Sales in the state of Bahia in eastern Brazil. It was collected along the highway in caatinga vegetation at 890 m elevation.

Additional collections examined. BRAZIL. BAHIA: along highway BR-116, caatinga, 890 m, 30 Mar. 1976, *G. Davidse, T. P. Ramamoorthy & D. M. Vital 11625* (MO).

Passiflora caatingae is placed in subg. *Tacsonioides*, where it most closely resembles *Passiflora mendoncae* Harms (Killip, 1938) but from which it differs by the linear-lanceolate stipules and smaller bracts. The bracts resemble those of *P. racemosa* Brot. of the monotypic subg. *Calopathanthus*, but this species possesses flowers with a folded operculum and strongly keeled sepals.

Passiflora pascoënsis L. Escobar, sp. nov. TYPE: Peru. Pasco: Oxapampa, Cordillera Yanachaga, 12 km E of main Oxapampa–Villa Rica road, remnant cloud forest, 2,100–2,200 m, 10°35′S, 75°15′W, 2 Mar. 1982, *A. Gentry & S. Smith 35939* (holotype, MO). Figure 3.

Subgeneris *Plectostemmatis* sect. *Decalobae* referenda, foliorum ambitu et coronae filamentorium exteriorum forma *P. alnifoliam* et arcte affines simulans, sed floribus et fructibus magnis necnon foliis inferne crasse reticulatis diversa.

Herbaceous vine. Plants pubescent, with irregular, curved to wavy, white to yellowish transparent trichomes 0.1–0.4 mm long. Stems 3-angular, striate. Leaf blades entire, ovate to elliptic, (5.3–)9.5–14.8 cm long, (3.8–)6.5–8.6 cm wide, 2–3-lobed at apex, shallowly cordate to rounded at base, entire at margins; leaf lobes subdeltate, lateral lobes 0.8–1.5 cm long, 0.7–1.3 cm wide, mid-lobes (lacking on some leaves) 0.2–0.4 cm long, 1.7–3.0 cm wide, mostly glabrous adaxially, pubescent on abaxial surface, with expanded fine veins forming an incrassate reticulum, slightly coriaceous; laminar nectaries variable in number, 5–ca. 40, mostly concentrated at base and between major lateral veins in upper ½ of abaxial surface; petioles 1.0–2.5 cm long, eglandular; stipules falcate, 0.5 1.0 cm long, ca. 0.5 mm wide. Peduncles paired, 2.0–2.5 cm long; bracts setaceous, scattered on upper ½ of peduncle, 0.4–0.6 cm long, 0.5 mm wide; flower stipe ca. 3 mm long. Flowers widely campanulate, 7–8 cm diam., pendent; hypanthium patelliform, ca. 0.4 cm long, 1.8–2.0 cm wide; sepals ovate, 2.7–3.0 cm long, 1.8–2.0 cm wide, obtuse at apex, coriaceous, greenish white; petals subequal to sepals, membranaceous, pinkish or white edged with pink; corona in 2 series, filamentous, cream-white banded with red-purple, the inner filaments 0.3–0.7 mm long, 0.5–0.8 mm wide and outer ones ca. 1.5 cm long, ca. 2 mm wide, dilated at apex; operculum closely plicate, erect, ca. 6 mm long, minutely crenulate at margin; ovary glabrous. Fruit ellipsoid, 2.5–3.0 cm long, 2.3–2.6 cm wide (pressed), yellow; seeds obovoid, ca. 3.5 mm long, ca. 2.0 mm wide, with ca. 7 rugulose transverse ridges, dark brown at maturity.

FIGURE 3. Holotype of *Passiflora pascoënsis* L. Escobar, deposited in the herbarium of the Missouri Botanical Garden (MO).

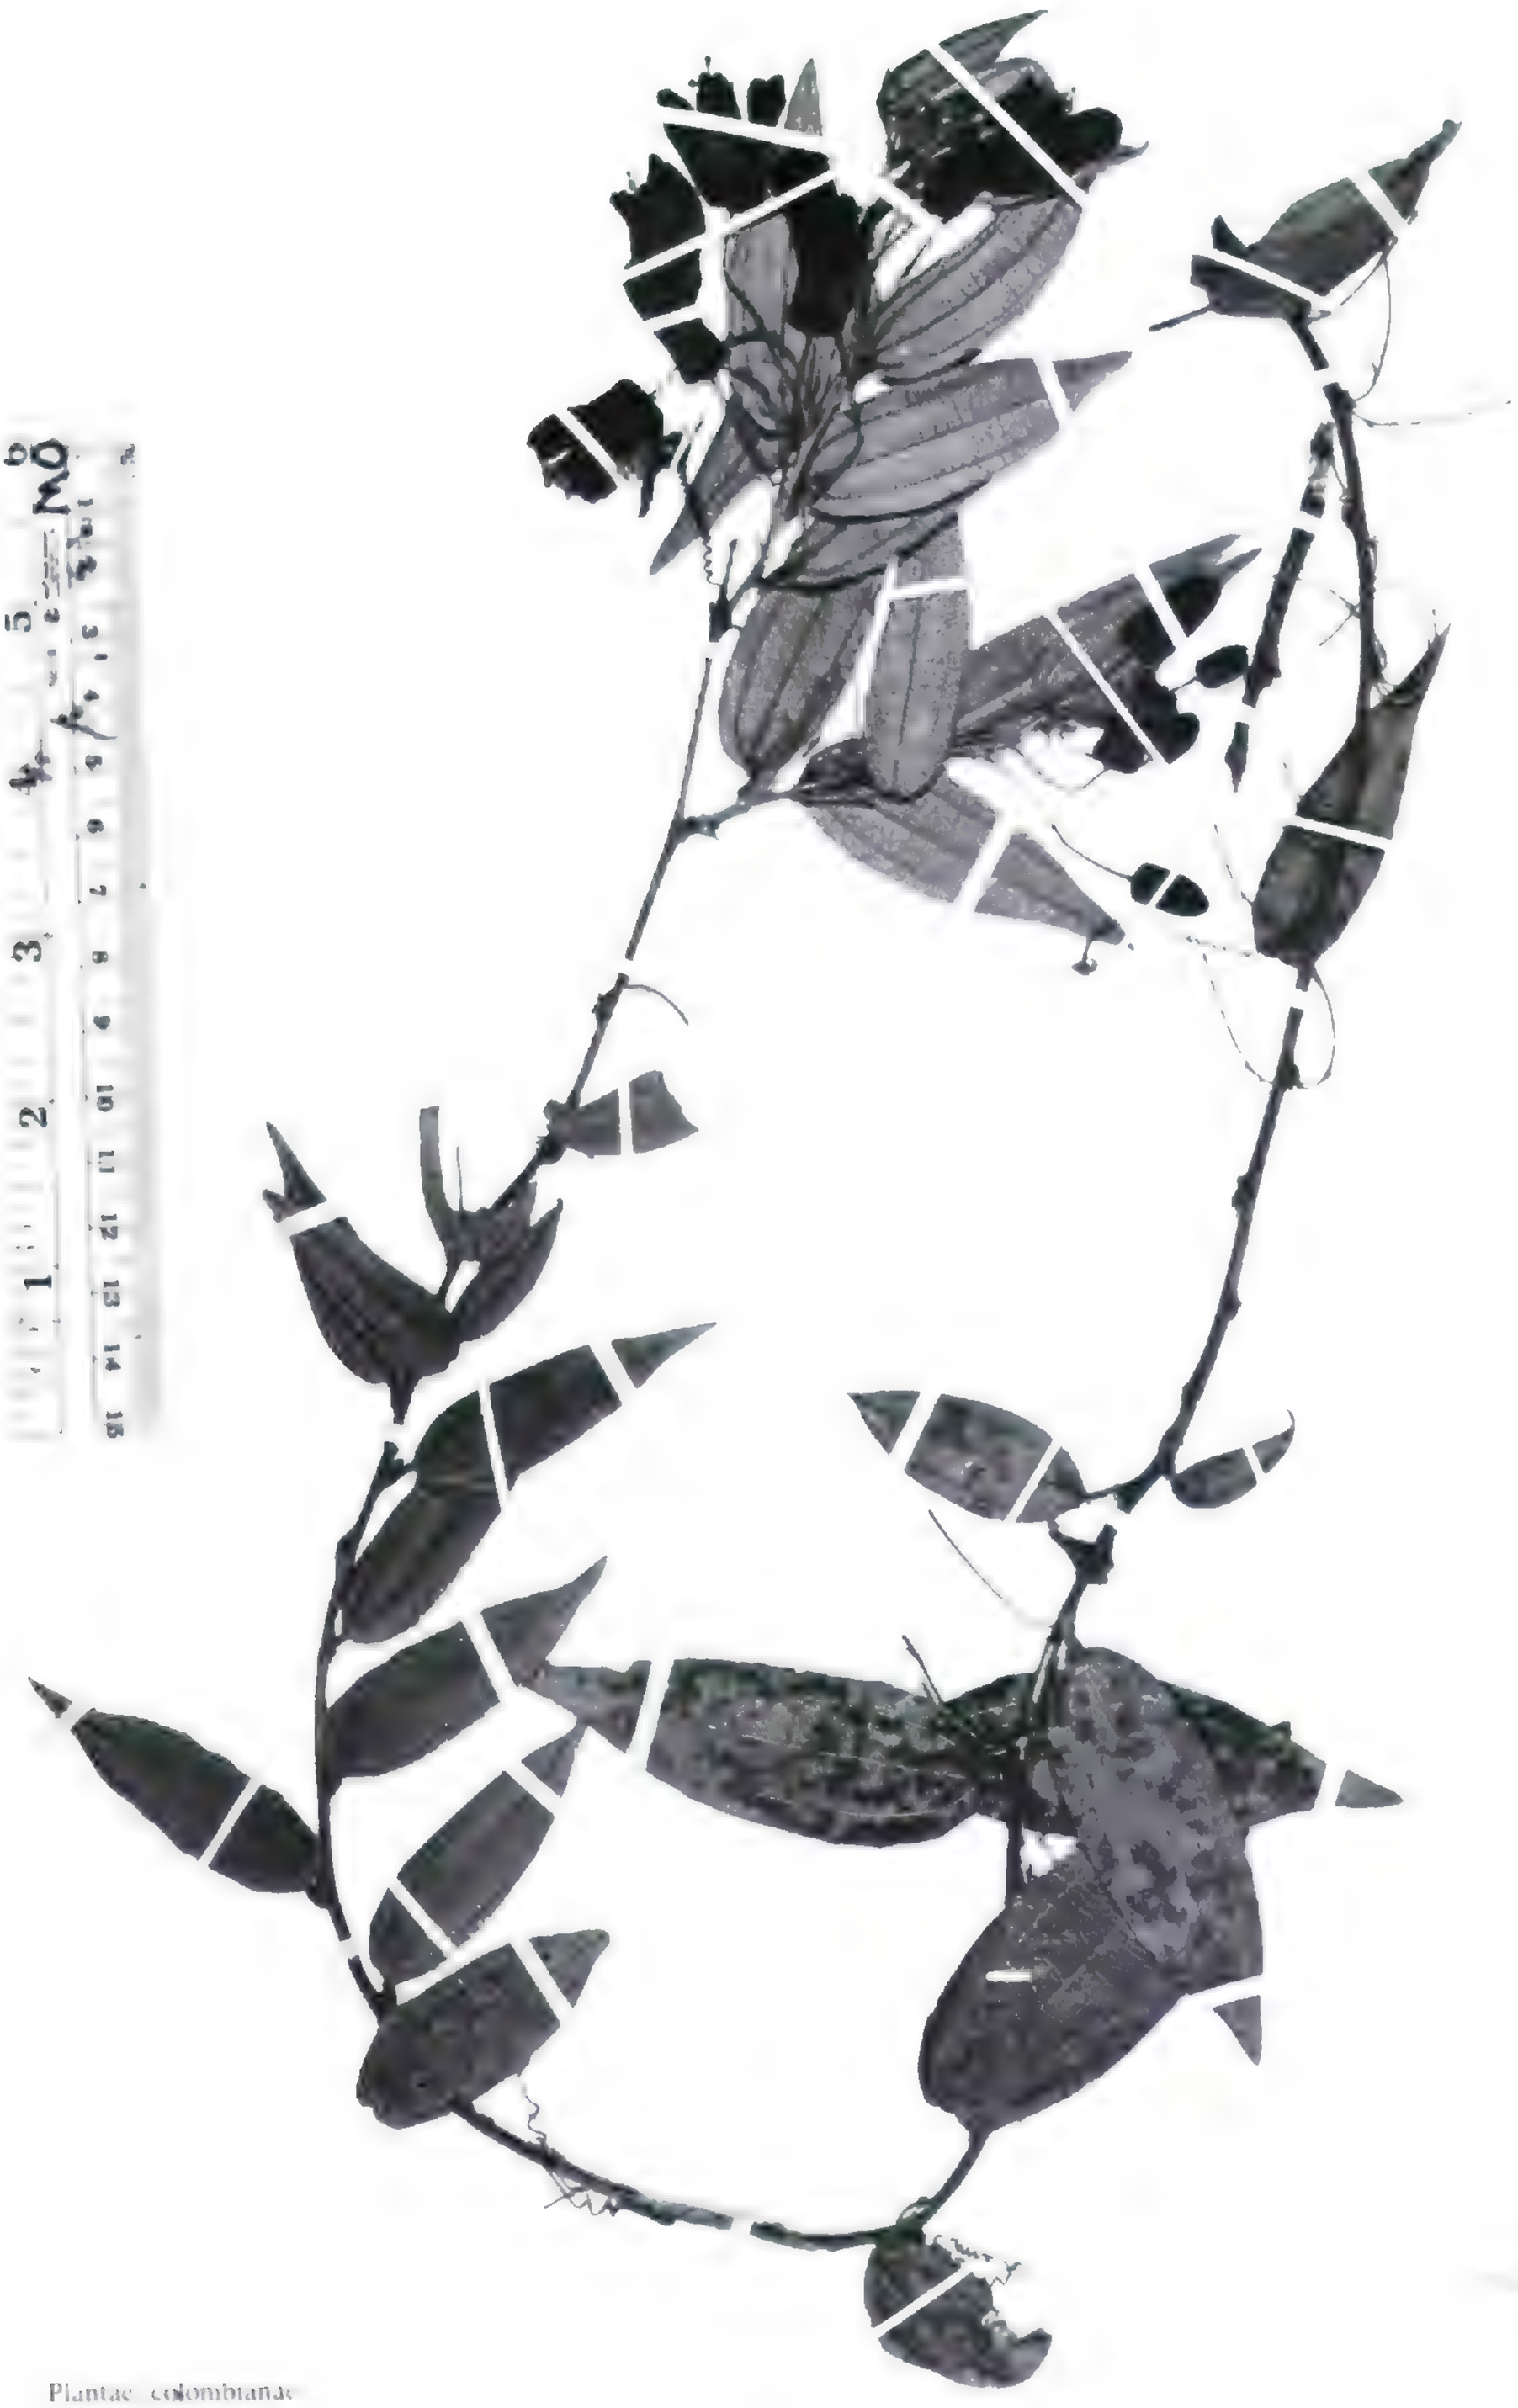

FIGURE 4. Holotype of *Passiflora sierrae* L. Escobar, deposited in the herbarium of the Smithsonian Institution (US).

FIGURE 5. Holotype of *Passiflora solomonii* L. Escobar, deposited in the herbarium of the Missouri Botanical Garden (MO).

Distribution. *Passiflora pascoënsis* is found on the borders of disturbed cloud forest at elevations of 1,850–2,500 m in the Department of Pasco, Peru.

Additional collections examined. PERU. PASCO: Oxapampa, Cordillera Yanachaga, new road in construction from Oxapampa to Villa-Rica, 7–9 km E of main road, 2,100–2,500 m, montane cloud forest, 10°45′S, 75°20′W, 1 Mar. 1982, *A. Gentry & D. Smith 35857* (MO); Valle de San Alberto, E of Oxapampa, above hydroelectric plant, at base of Cordillera Yanachaga; roadside forest remnants, 1,900 m, 1 Jan. 1984, *R. Foster, M. Chanco & J. Alban 7714* (HUA, MO); pastures in vicinity of Oxapampa, ca. 2 km E of the village, secondary growth, 1,850 m, 10°35′S, 75°35′W, 10 Mar. 1984, *S. Knapp, J. Mallet & W. Brack 6319* (MO, NY, US).

This beautiful, large-flowered species is placed in subg. *Plectostemma* sect. *Decaloba* (Killip, 1938), where it resembles members of the *Passiflora alnifolia* complex in leaf shape and form of the outer coronal filaments. It is easily distinguished from those species by the large flowers and fruits and by the incrassate reticulum formed by expansion of the fine veins of the lower leaf surface.

Passiflora subg. **Porphyropathanthus** L. Escobar, subgen. nov. TYPE. *Passiflora sierrae* L. Escobar.

Nectariis petiolaribus, operculo haud plicato necnon *Passiflora lancifoliae* subgen. *Chloropathantho* similis, sed cum eo petalis manifestis 1.3–1.8 cm longis, seminibus transverse rugulosis et nectariis in foliorum lamina sitis incongruum.

Passiflora sierrae L. Escobar, sp. nov. TYPE: Colombia. Magdalena: Sierra Nevada de Santa Marta, southeastern slopes, hoya del Río Donachuí, near Col, 3,100–3,070 m, 9 Oct. 1959, *J. Cuatrecasas & R. Romero-Castañeda 24675* (holotype, US; isotype, COL). Figure 4.

Iisdem notulis jam sub subg. *Porphyropathantho* indicatis unica.

Herbaceous vine. Plants pubescent, with straight to wavy, reddish trichomes ca. 0.5 mm long. Stems angulate, striate. Leaf lobes entire, ovate to lanceolate, (3.8–)4.3–9.0 cm long, (1.4–)2.4–4.5 cm wide, acuminate and mucronate at apex, rounded at base, entire at margins, stiff-coriaceous, lustrous on adaxial surface, yellow-green, pubescent on veins on both surfaces; laminar nectaries 0–3, scarcely visible between major veins of abaxial surface; petioles 3–6 mm long, with 1 pair of stipitate, cup-shaped nectaries ca. 1 mm diam. at apex; stipules linear-lanceolate, ca. 5 mm long, reddish. Peduncles paired, 1.5–2.0 cm long; bracts 3, scattered on upper ½ of peduncle, linear-lanceolate, 1.5 2.0 mm long, ca. 0.3 mm wide; flower stipe 1.6-2.2 cm long. Flowers campanulate, 1.7–2.0 cm long, 3.5–4.0 cm diam., pendent, red-purple; hypanthium patelliform, 3 4 mm long, 0.5–1.0 cm wide; sepals oblong, 1.7–2.0 cm long, 2–6 mm wide, obtuse at apex, subcoriaceous, pubescent on abaxial surface; petals oblong, 1.3–1.8 cm long, 1.3–3.5 mm wide, rounded at apex, delicately membranaceous, pink to light purple; corona in 1 series, filamentous, ca. 1.5 mm long, but irregular, each filament ca. 0.1 mm wide; operculum erect, ca. 2 mm long, nonplicate, crenate at margin; ovary ellipsoid, glabrous, light green. Fruits globose, ca. 1.5 cm long, 1.3 cm wide (pressed); seeds obovoid, ca. 6.0 mm long, ca. 3.1 mm wide, with ca. 13 rows of transverse rugulose ridges.

Distribution. This species is known only from subpáramo vegetation in the Sierra Nevada de Santa Marta in northeastern Colombia, where it is found in dense shrubby growth above 3,000 m elevation.

Additional collections examined. COLOMBIA. MAGDALENA: Sierra Nevada de Santa Marta, entre San Pedro y cabeceras del Río Sevilla, ca. 3,195 m, 31 Jan. 1959, *H. Barclay & P. Juajibioy 6783* (COL, MO); Transecto del Alto Buriticá, cuchilla y cerros a 3,300 m, lev. 33, 9 Aug. 1977, *R. Jaramillo M., T. van der Hammen, M. A. Cleef & O. Rangel 5472* (COL).

The presence of petiolar nectaries and purple flowers with a nonplicate operculum, suggests a relationship to *P. lancifolia* Desv., of subg. *Chloropathanthus* (Harms, 1925; Killip, 1938), which is known only from Jamaica. Unlike that species and others of subg. *Chloropathanthus*, *P. sierrae* has well-developed petals, poorly developed laminar foliar nectaries, and seeds with transverse rugulose ridges. This unique combination of characters requires the creation of a new subgenus. Data from pollen studies (Presting, 1965; Spirlet, 1965; Escobar, unpubl.) suggest that several purple- or red-flowered species (usually with a tubular hypanthium and therefore presumably hummingbird-pollinated) have arisen independently from the large and variable subg. *Plectostemma*. They do not suggest that all species with the hummingbird-pollinated syndrome are monophyletic.

Passiflora solomonii L. Escobar, sp. nov. TYPE: BOLIVIA. LA PAZ: Prov. Nor Yungas, 9.1 km NE (below) Chuspipata on road to Yolosa, 2,400 m, 16°16′S, 67°47′W, 29 Oct. 1984,

J. C. Solomon & M. Nee 12592 (holotype, MO; isotype, HUA). Figure 5.

Foliorum forma, nisi ambitu transverse lineari (nec ovato), *P.* (subg. *Plectostemma*) *exoperculatam* Mast. referens, sed haec a nostra pedunculis longioribus, foliorum lobis brevioribus, nectariis petiolaribus prominulis necnon coronae filamentis capitellatis differt.

Herbaceous vine. Plants sparsely pubescent with wavy, transparent trichomes ca. 0.1 mm long. Stems angulate, striate. Leaf blades transversely linear, coriaceous, sparsely pubescent on abaxial surface, dull yellowish green, 2-lobed, the lobes divergent by ca. 90° from mid-vein, each 1.1–1.5 cm long, 7.1–10.0 cm wide, acuminate and mucronate at apex, shallowly cordate at base, entire at margins; petioles 4–9 mm long, eglandular; stipules linear-lanceolate, ca. 2.5 mm long, ca. 0.2 mm wide. Peduncles paired, 6–12 mm long, very slender; bracts 3, setaceous, ca. 2 mm long, drying black, scattered along peduncle; flower stipe ca. 1 mm long. Flowers campanulate, 2 3 cm diam., pendent, greenish white; hypanthium patelliform, 2.5–3.0 mm long, ca. 3.5 mm wide; sepals triangular, 8–12 mm long, ca. 10 mm wide at base, acute at apex; petals lanceolate, 11 12 mm long, 3–6 mm wide, delicately membranaceous, greenish white; corona in 2 series, the outer series linear, 7–8 mm long, ca. 1 mm wide, the inner filaments ca. 3 mm long, 0.2 mm wide, operculum dependent then recurved, loosely plicate; ovary globose, pubescent. Fruits unknown.

Distribution. *Passiflora solomonii* is known only from the type locality in La Paz Department of Bolivia at 2,400 m elevation.

The unusual leaf shape of *Passiflora solomonii* is reminiscent of *P. exoperculata* of subg. *Plectostemma* but is transversely linear rather than transversely ovate; *P. exoperculata* also differs from *P. solomonii* in possessing prominent petiolar nectaries and capitellate inner coronal filaments as well as longer peduncles and shorter leaf lobes.

A REVISION OF MESOAMERICAN *PSYCHOTRIA* SUBGENUS *PSYCHOTRIA* (RUBIACEAE), PART III: SPECIES 48–61 AND APPENDICES[1]

Clement W. Hamilton[2]

Group 7. The *tenuifolia* Group

Shrub or small tree; young stems glabrous or puberulent; stipules often sheathing, ovate to triangular with apex long-biacuminate in *P. tenuifolia* (Fig. 2e), uniform in color, glabrous or puberulent, caducous. *Leaf* blades elliptic (to sometimes slightly ovate in *P. limonensis*), drying green-brown or red-brown; secondary veins 8–21(–24) pairs, *diverging (60°–) 70°–90°(–95°), brochidodromous with collector vein near margin*, the axils lacking domatia or hairs; tertiary veins orthogonal reticulate (to sometimes percurrent in *P. limonensis*). *Inflorescences umbelliform panicles of cymes* (Fig. 7f), the peduncle lacking or no more than 2 cm long; *secondary axes in one pair per rank*; *bracts not conspicuously enlarged. Corolla tubes 1.5–2 mm long, the lobes without apical extensions. Fruit* when dry ellipsoid; *persistent calyx inconspicuous or a beak*; seed dorsal surface with 4–5 longitudinal furrows (often irregular in *P. limonensis*), the ventral surface with 2 longitudinal furrows (often incompletely divided in *P. limonensis*).

The two species in the group, *Psychotria limonensis* and *P. tenuifolia*, are both widespread throughout Mesoamerica (Figs. 32, 33) and often occur together in lowland forest.

Both species appear to be normally distylous with no between-morph asymmetry in floral part lengths.

48. Psychotria limonensis K. Krause, Bot. Jahrb. Syst. 54, Beibl. 119: 43. 1916. TYPE: Costa Rica. Limón: Puerto Limón, July 1898 (fr), *Pittier 12681* (holotype, B, destroyed, fragment, F, photo, F neg. no. 518; isotypes, K, US). Figures 7f, 32.

Psychotria limonensis K. Krause var. *laxinervia* Loesener, Repert. Spec. Nov. Regni Veg. 18: 361. 1922. TYPE: Mexico. Chiapas: Ruinas del Palenque, 10 Mar. 1911 (fr), *C. Seler & E. Seler 5463* (holotype, B, destroyed, fragment, F, photo, US; isotype, GH).

Shrub to small tree 0.5–3(5) m tall; young stems glabrous or sparsely puberulent, the bark smooth; stipules sheathing, rounded-ovate to triangular, 6–9 × 5–10 mm, glabrous, caducous, leaving a pale or red-brown ridge with red-brown fringe. *Leaves* petiolate; petioles 2.5–6 cm long, glabrous, flat or channeled above; blades membranous to chartaceous, elliptic to slightly ovate, the apex acuminate, the base narrowly cuneate to attenuate, (12–)17–29 × (6–)7.5–15 cm, glabrous above and below, drying red-brown to green-brown; secondary veins (10)15–21(–24) pairs, diverging (60°–)70°–90°(95°), brochidodromous with collector vein undulating near margin, straight or slightly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous to evident, orthogonal reticulate to percurrent. *Inflorescences* terminal or pseudoaxillary, umbelliform panicles of cymes (Fig. 7f); panicle branched to 4–5 degrees; main axis 1.5–5.5 cm long, the peduncle usually lacking or to 2 cm long; secondary axes in (4–)5–6 ranks, the first-rank axes 2, 1.5–5.5 cm long, the second-rank axes 2, 1–3 cm long, the third-rank axes 2, 0.6–2 cm long, the fourth-rank axes 2, 0.3–1 cm long, the fifth-rank axes 2, 0.3–0.5 cm long, the sixth-rank axes 2, 0.1–0.2 cm long; cymes branched to 1–2 degrees; bracts and bracteoles acute-triangular, 0.5–1.2 mm long, minutely ciliate. *Flowers* pedicellate, the pedicels 0.5–1 mm long; calyx cup-shaped, the tube 0.2 mm long, the lobes (4–)5, triangular, to 0.5 mm long, glabrous or puberulent; corolla white, the tube cylindrical, 1.5–2 × 1–1.5

[1] Part I: Introduction and Species 1–16, and Part II: Species 17–47 appeared in the preceding two issues of the *Annals of the Missouri Botanical Garden*, Volume 76: 67–111, 386–429.

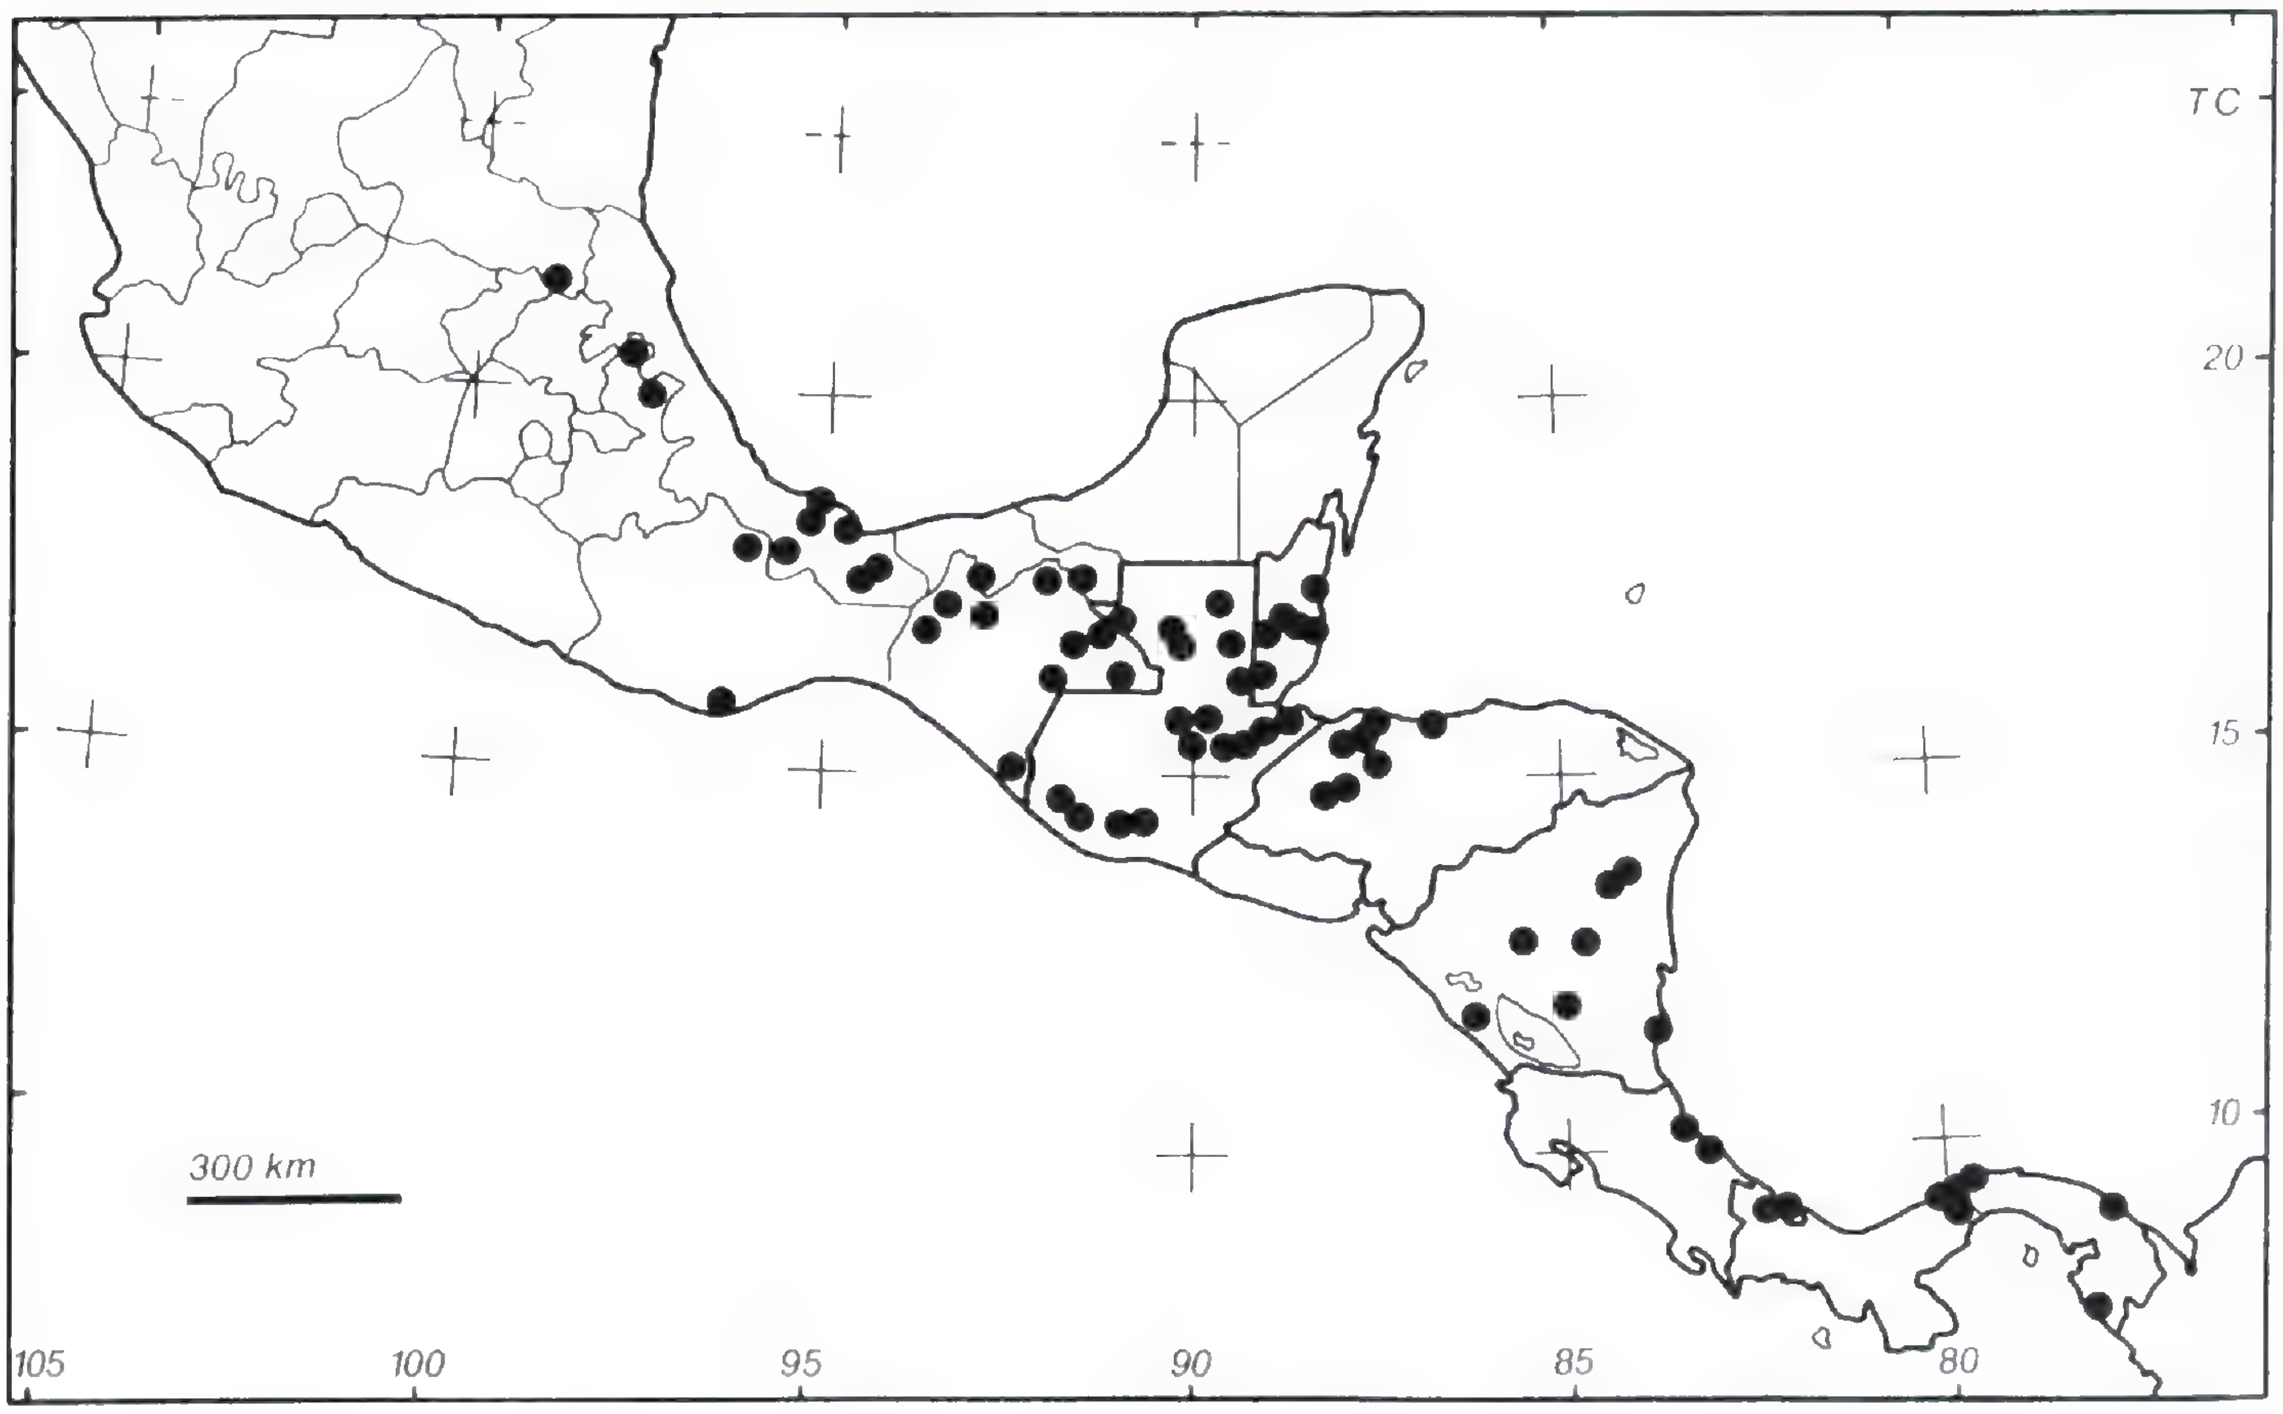

FIGURE 32. Distribution of *Psychotria limonensis* in Mesoamerica.

mm, white pubescent in throat, the lobes (4)5, lanceolate, 1.5–2 × 0.8 mm; stamens (4)5, the filaments 1.5–2 mm long in pins, 3–3.5 mm long in thrums, the anthers 0.7–0.8 mm long; style 3–3.5 mm long in pins, 2.2 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid, (3.5–)4(–4.5) mm long, (3–)3.5(–4) mm diam., maturing red, drying dark red-brown; persistent calyx inconspicuous or a beak to 0.3 mm long; seed dorsal surface with 4–5 deep often irregular longitudinal furrows, the ventral surface with 2 often incompletely divided longitudinal furrows.

Distribution (Fig. 32). Common from Mexico through Panama, especially southern Mexico to western Honduras. The species occurs at elevations of 0–1,700 m, most frequently at 700 m and below, and in tropical moist to wet to sometimes premontane wet forest with equatorial to tropical (usually equatorial-tropical) climate. *Psychotria limonensis* has been collected in flower throughout the year—it appears to flower throughout the year in Panama but just primarily May–August in the rest of its range. Fruits form throughout the year, primarily August–April.

Psychotria limonensis may be recognized by its broad-elliptic, thin-membranous leaves, brochidodromous secondary veins with collector vein near margin, broad umbelliform inflorescences, and small (usually 4 mm long) ellipsoid to subspherical fruit. Leaves on Mexican and Guatemalan specimens have fewer secondary veins than those from elsewhere; the secondaries diverge characteristically at acute (vs. right) angles in Nicaragua.

Psychotria granadensis Bentham in Oersted, Vidensk.

Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1852: 34. 1853. *Uragoga granadensis* (Benth.) Kuntze, Revis. Gen. Pl. 2: 960. 1891. TYPE: Nicaragua: Granada, *Oersted s.n.* (holotype, C, n.v., photo, F neg. 22833).

Psychotria sulzneri Small, Fl. Miami, 176. 1913. No type cited.

Shrub 0.5–2(–3) m tall; young stems glabrous to puberulent, the bark smooth; stipules ovate, long-biacuminate (Fig. 2e), 8–13 × 3–6 mm, glabrous to puberulent, caducous, leaving pale ridge with red-brown fringe. *Leaves* petiolate; petioles (0.3–)0.5–4 cm long, glabrous to puberulent, grooved above; blades membranous, narrow- to medium-elliptic, the apex acuminate or sometimes acute, the base attenuate, (4–)7.5–23 × (1–)2.5–6(–7.7) cm, glabrous above, glabrous to puberulent below, the midvein puberulent below, drying green-brown to sometimes red-brown; secondary veins 8–18 pairs, diverging 70°–80°, brochidodromous with collector vein fairly near margin, slightly arcuate, prominulent and puberulent below, the axils lacking domatia or hairs; tertiary veins inconspicuous to evident, orthogonal reticulate, the tertiary loops between secondary loops and margin often evident. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3–4(–5) degrees; main axis 1.4–4.5 cm long, the peduncle to 2 cm long or lacking; secondary axes in (2)3(4) ranks, the first-rank axes 2, (0.9–)1.8–3 cm long, the second-rank axes 2, (0.4–)0.8–1.2 cm long, the third-rank axes (1)2, 0.1–0.5 cm long, the fourth-rank axes 2, 0.1–0.3 cm long; cymes branched to 2–3 degrees; bracts and bracteoles lanceolate to linear, 0.5–1 mm long, puberulent. *Flowers* pedicellate, the pedicels 0.5–1.5 mm long; calyx cup-shaped, the tube 0.2–0.3 mm long, the lobes 5, triangular, 0.3–0.5 × 0.5 mm, minutely ciliate; corolla white, the tube cylindrical, 1.5–2 × 0.8–1 mm, white pubescent in throat, the lobes 5, triangular, 0.7–1 × 0.5–0.7 mm; stamens 5, the filaments 1–1.5 mm long in pins, 2.5–3 mm long in thrums, the anthers 0.5–0.7 mm long; style 2–3 mm long in pins, 1.5 mm long in thrums, the branches linear. *Fruit* ellipsoid when dry, 4–5 mm long, 3–4.5(–5) mm diam., maturing red, drying red-brown; persistent calyx inconspicuous or a tubular beak to 0.5 mm long; seed dorsal surface with 4–5 shallow longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 33). Widespread from Mexico through Panama at 0–2,000 m elevation, mostly below 1,000 m, in tropical dry to premontane moist forest with equatorial to tropical climate. *Psychotria tenuifolia* occurs also in Florida, Cuba, and Hispaniola. It has been collected in flower throughout the year, primarily May–July, and in fruit throughout the year, primarily August–February.

This variable species includes *P. sessilifolia* (Mexico; narrow leaves), *P. granadensis* (Nicaragua; broad leaves), and *P. sulzneri* (Florida; small, narrow leaves).

Psychotria tenuifolia may be recognized by its narrow-elliptic, thin-membranous leaves; brochidodromous secondary veins with collector vein near the margin; small umbelliform panicles of cymes; and small (4–5 mm long) ellipsoid fruits. Specimens from Honduras and further north are more puberulent, especially on the leaf underside, than from Nicaragua and south. Honduran inflorescences have especially conspicuous linear bracts.

GROUP 8. THE *CHLOPHYLLA* GROUP

Shrub or subshrub or herb (sometimes *P. hammelii* and *P. rosulatifolia*) or small tree (*P. calophylla*); *young stems* glabrous or *red-brown pubescent*; *stipules usually sheathing*, ovate or truncate *with apex usually biaristate or bifurcate* (Fig. 2g), uniform in color, glabrous or ferrugineous-pubescent (or fringed in *P. insueta*), caducous or often persistent at terminal 3–5 nodes in *P. hammelii* and *P. psychotriifolia*. *Leaf* blades elliptic or obovate or oblanceolate (or lanceolate in *P. rosulatifolia*), drying red-brown to green-brown, sometimes paler below; secondary veins (7)10–25(–42) pairs, diverging (45°–)50° 85°(110°), usually brochidodromous with collector vein (Fig. 3c) or sometimes without collector vein or eucamptodromous, the axils lacking domatia; tertiary veins orthogonal reticulate (or sometimes percur-

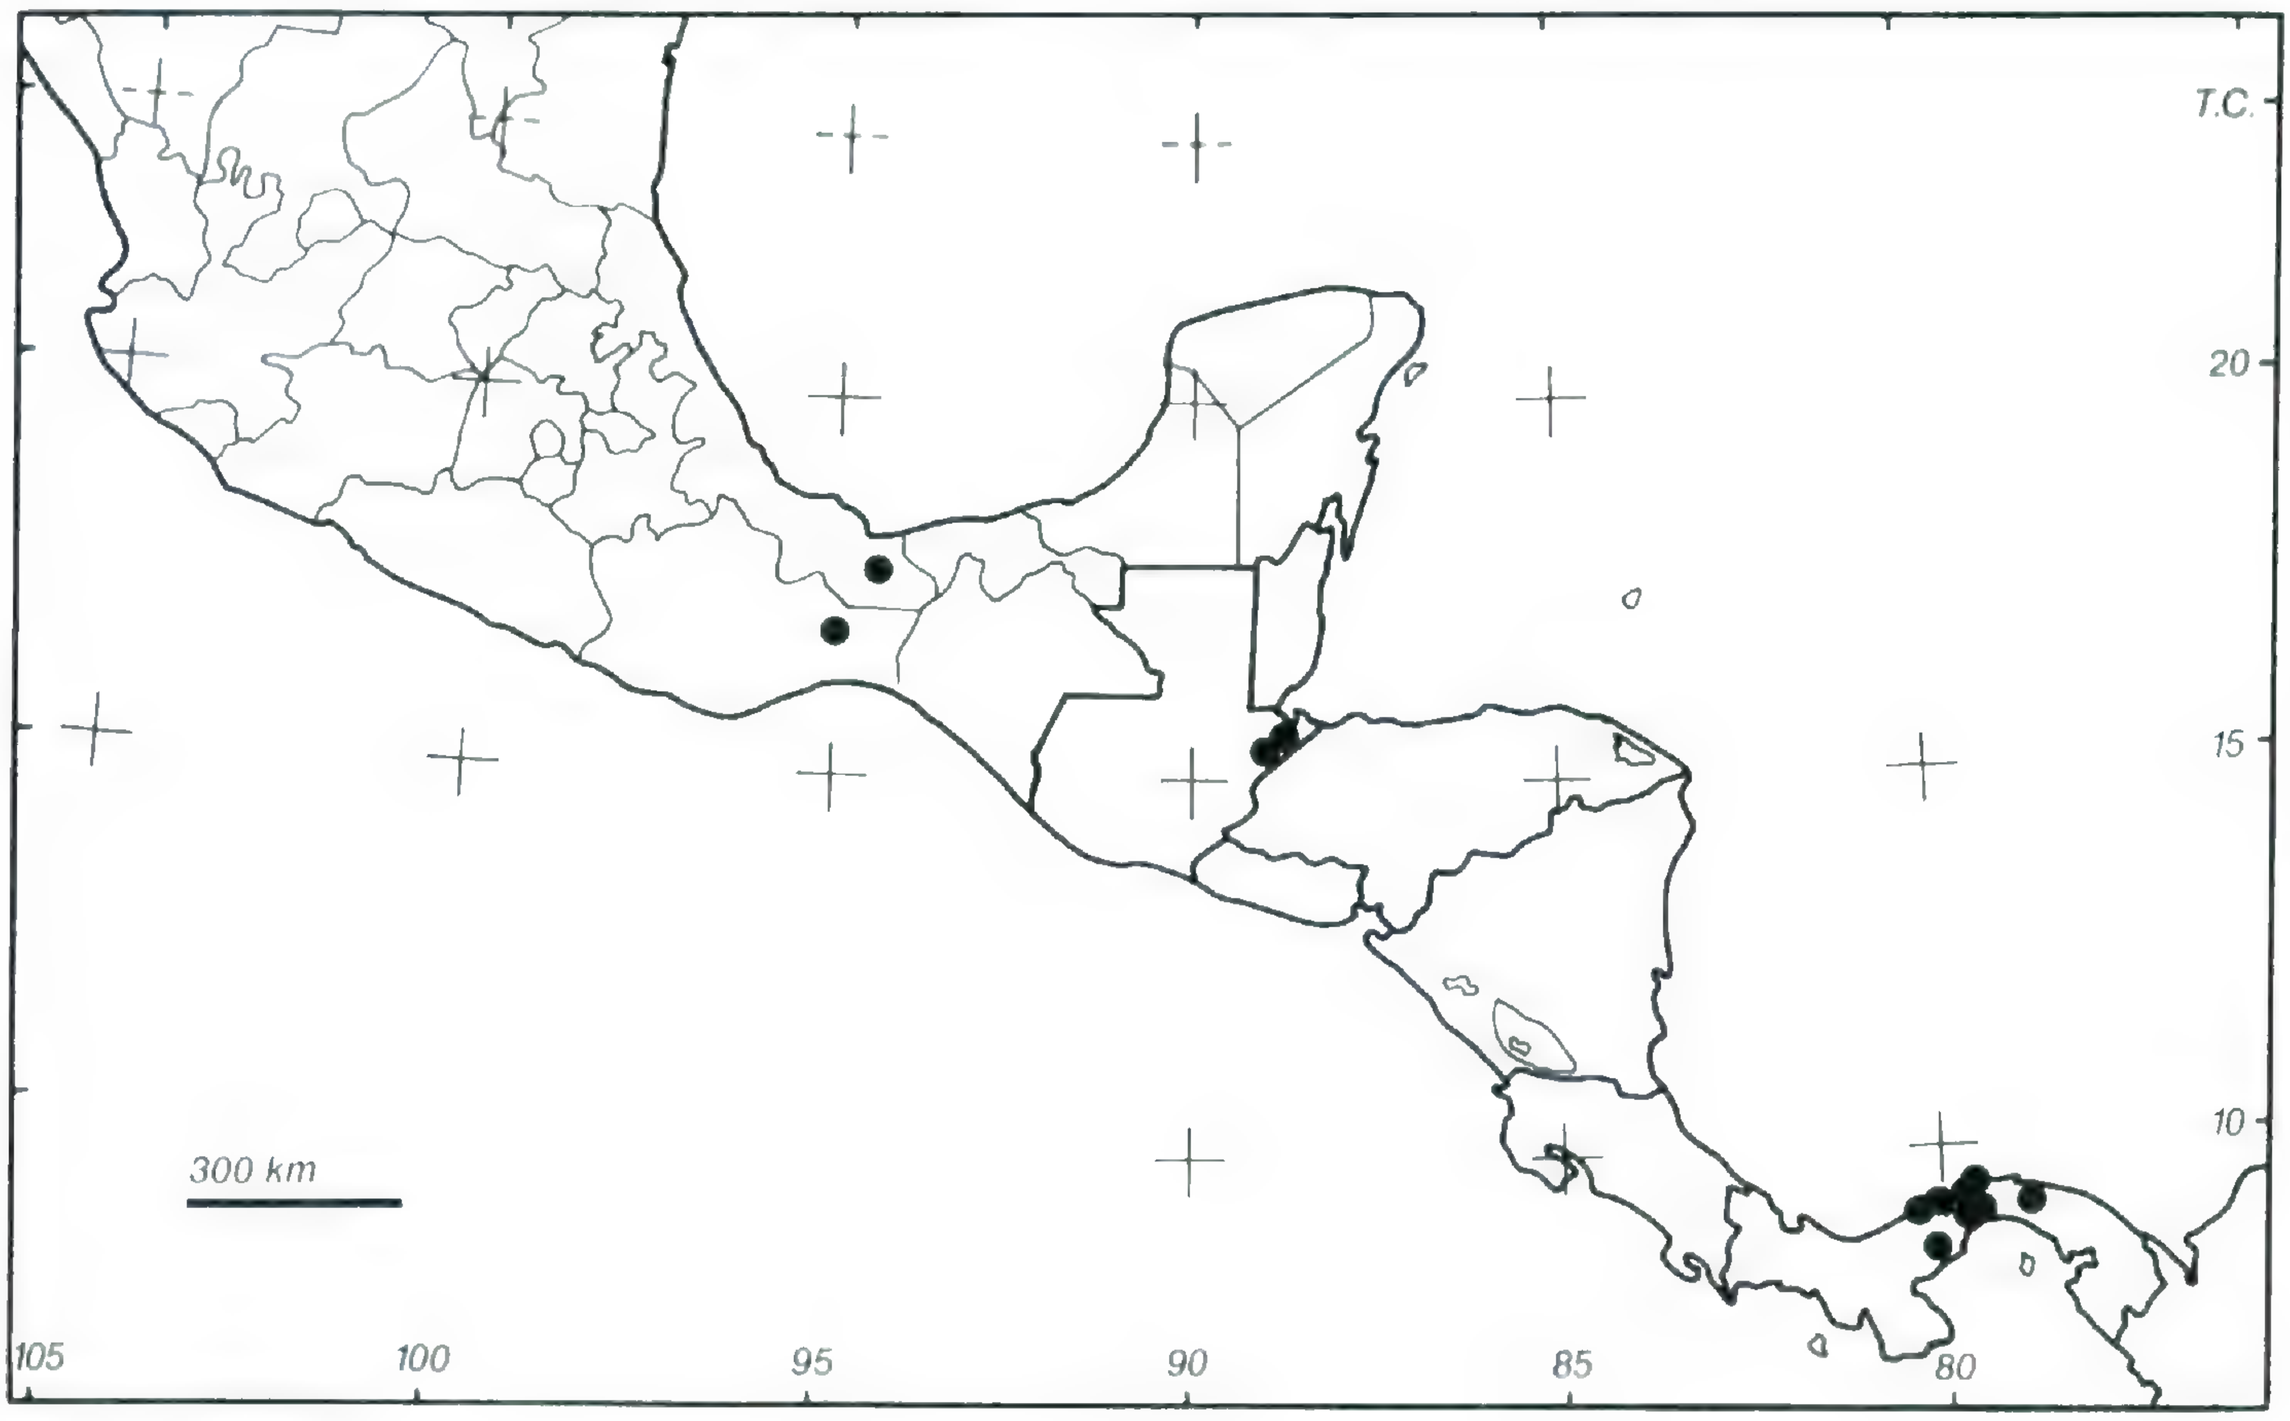

FIGURE 34. Distribution of *Psychotria calophylla*.

rent in *P. calophylla*, *P. insignis*, and *P. rosulatifolia*). *Inflorescences* panicles of cymes or of glomerules, pedunculate except for *P. insignis*, *P. psychotriifolia*, and often *P. calophylla*; secondary axes in 1–2(–3) sometimes size-differentiated pairs per rank and/or in clusters (*P. alfaroana*, *P. chitariana*, *P. dressleri*; Fig. 7d), delicate only in *P. rosulatifolia*; *bracts often conspicuous*. *Corolla* tubes (1.5–)2–5 mm long (10–12 mm in *P. dressleri*), *the lobes usually with apical extensions, protuberances, or thickenings*. *Fruit when dry ellipsoid*; *persistent calyx* inconspicuous or *a beak or a tube* to 3.5 mm long; seed dorsal surface with (3–)4–5 usually deep longitudinal furrows, the ventral surface with 2 shallow, often incompletely divided longitudinal furrows.

Only *Psychotria calophylla* (Fig. 34) and *P. psychotriifolia* (Fig. 35) are not narrow endemics; only the former has been collected north of Nicaragua. *Psychotria rosulatifolia* and *P. dressleri* occur in eastern Panama (Figs. 35, 36) and share inflorescence secondary axes often in size-differentiated pairs, and therefore may be closely related; but phylogenetic relationships among these mostly narrowly endemic species are difficult to hypothesize.

Of the twelve species in the group, four are normally distylous; only one of those—*Psychotria alfaroana*—shows any between-morph asymmetry in floral part length. *Psychotria rosulatifolia* appears pin-monomorphic, based on five flowering collections examined. *Psychotria monteverdensis* appears long-homostylous. The remaining six species are represented by few or no flowering collections and cannot be assessed.

50. Psychotria alfaroana Standley, J. Wash. Acad. Sci. 18: 273. 1928. TYPE: Costa Rica. Guanacaste: El Arenal, 500 m, 18 Jan. 1926 (fr), *Standley & Valerio 45179* (holotype, US). Figure 36.

Subshrub 0.3–0.6 m tall; young stems glabrous, the bark irregularly furrowed longitudinally; stipules sheathing with the sheath 5–7 mm long, biaristate with the extensions 7–12 mm long, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 7–25(30) mm long, glabrous, grooved above; blades membranous, obovate, the apex acuminate to cuspidate, the base attenuate, 11–29 × 4.5–10 cm, glabrous above, glabrous below with minute organic detritus adhering to midvein, drying dull green; secondary veins (7–)11–14(–16) pairs, diverging (60°–)70°–80°(-90°), eucamptodromous, arcuate at midvein—then straight—then arcuate near margin, or constantly arcuate, elevated below, glabrous,

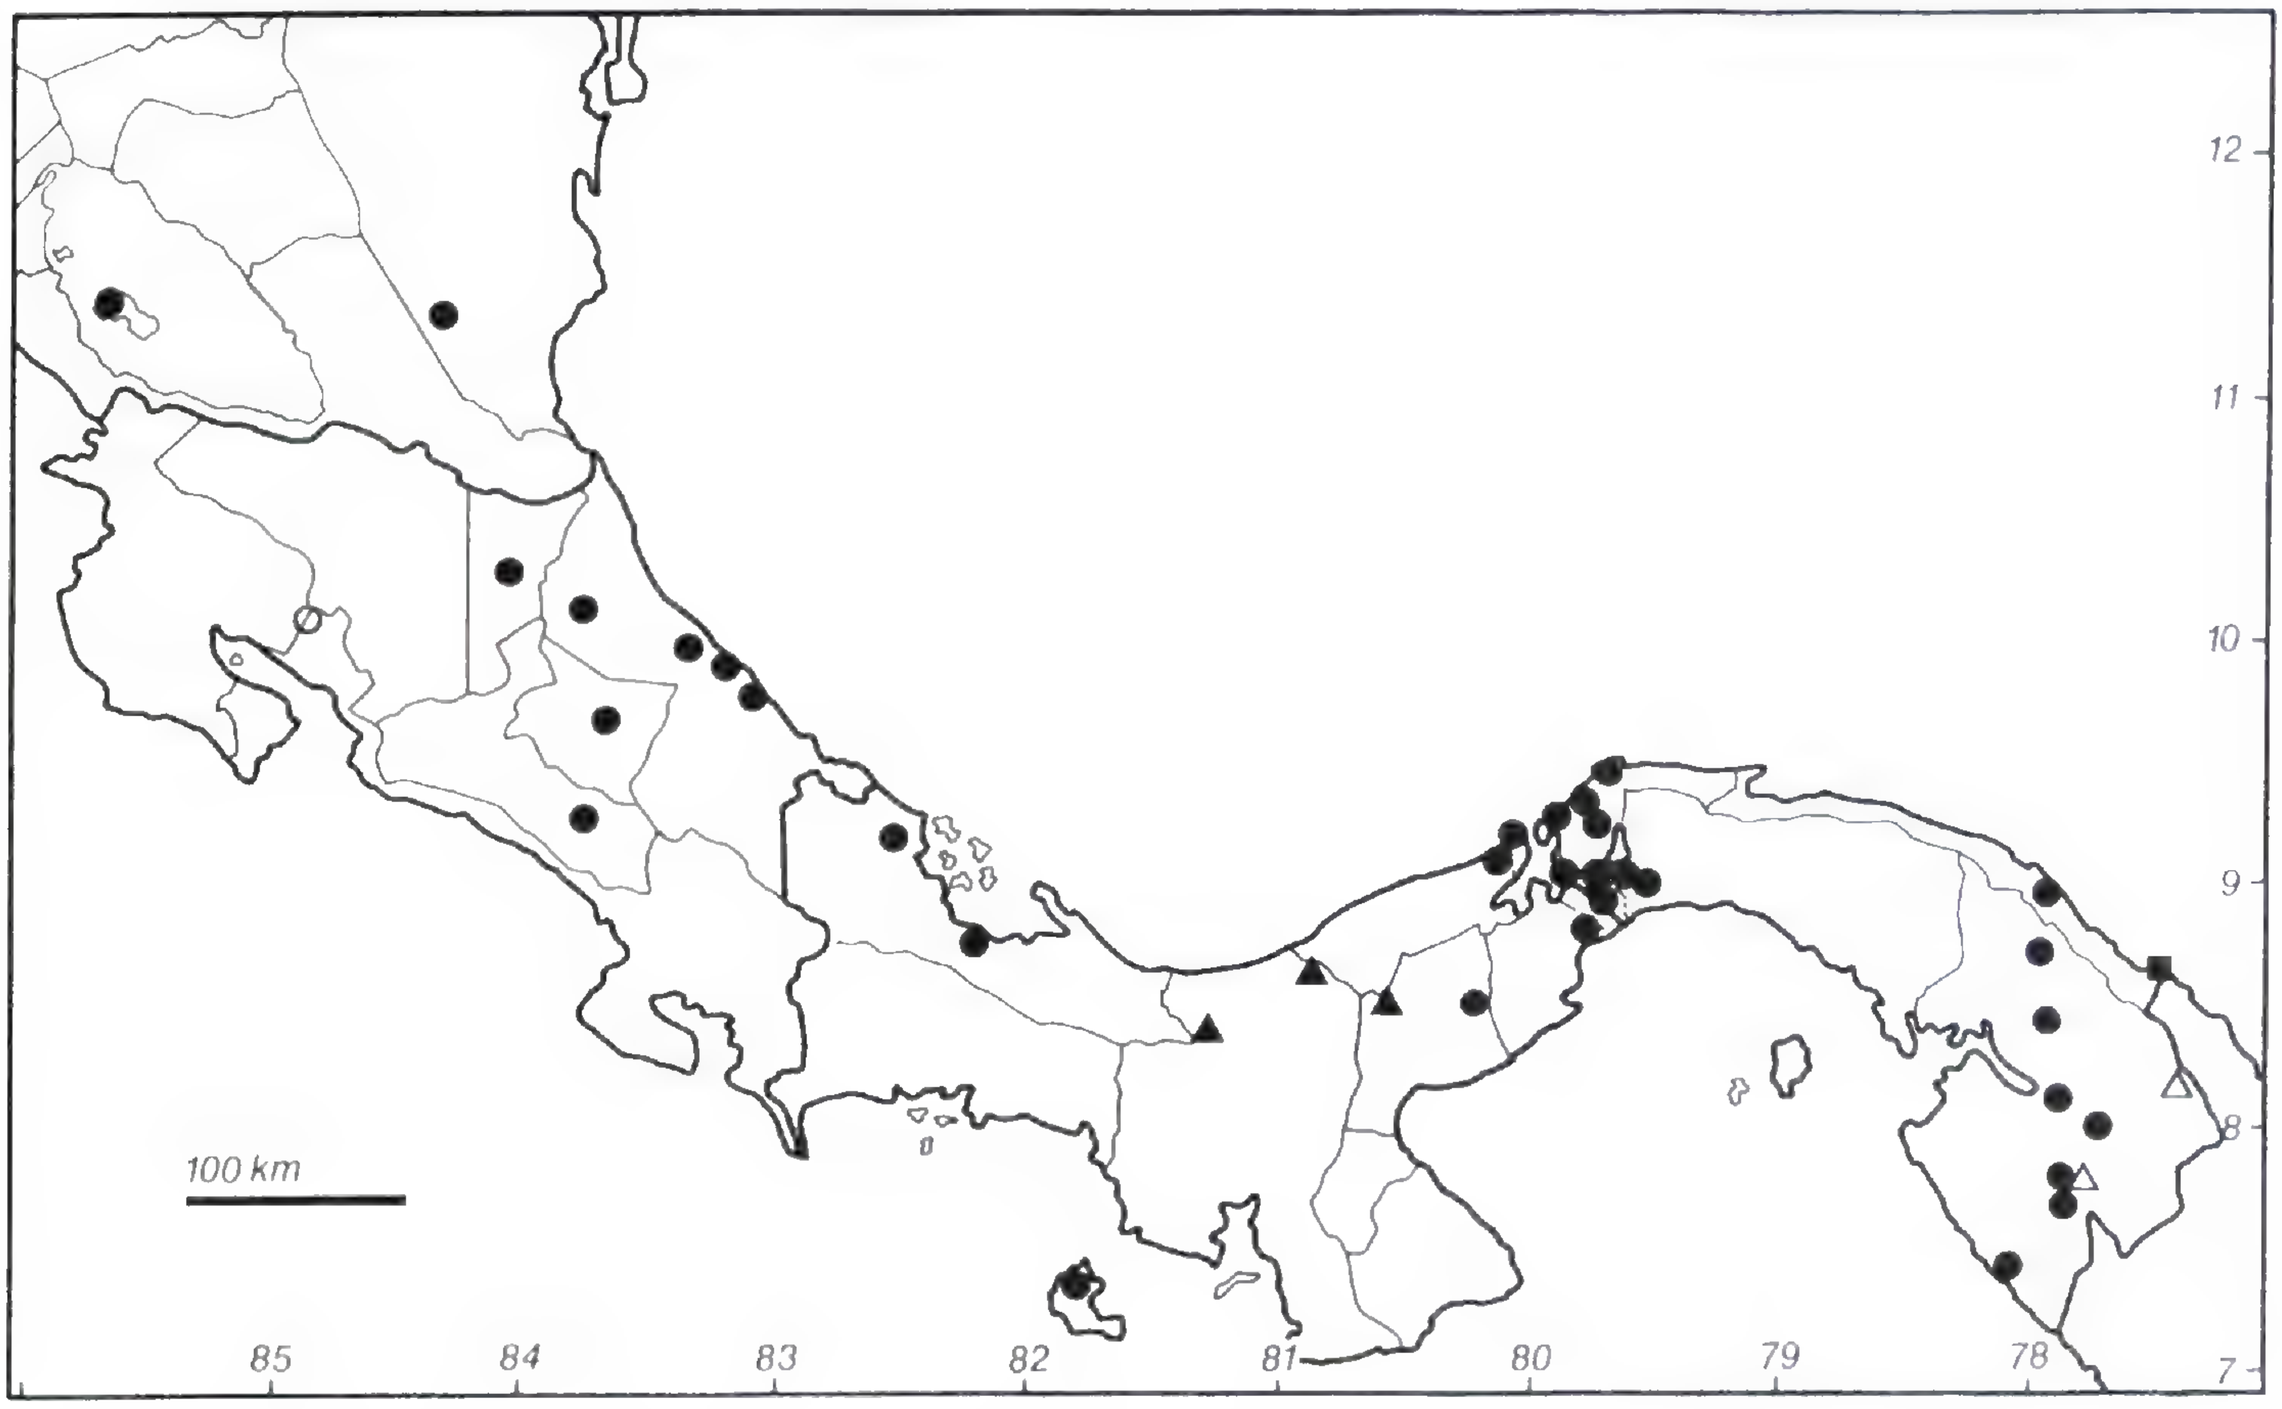

FIGURE 35. Distributions of *Psychotria insignis* (solid square), *P. insueta* (solid triangles), *P. monteverdensis* (open circle), *P. psychotrifolia* (solid circles), and *P. rosulatifolia* (open triangles) in Mesoamerica.

the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate. *Inflorescences* terminal, compact-globose panicles of cymes; panicle branched to 2–3 degrees; main axis (1–)2–4 cm long, the peduncle 1–3 cm long; secondary axes in 1 cluster, several, 5–7 mm long; cymes branched to 1–2 degrees; bracts not evident. *Flowers* pedicellate, the pedicels 1–2 mm long; calyx drying pale brown, cup-shaped, the tube 1 mm long, the lobes 5, linear, 1–2 × 1 mm, glabrous to sparsely ciliate; corolla white, the tube cylindrical, 2.5–4 × 2 mm, white pubescent in throat, the lobes 5, linear, thickened at apex, 2–3 × 1 mm; stamens 5, the filaments 2.5 mm long in pins, 6 mm long in thrums, the anthers 0.8–1.2 mm long; style 4–5 mm long in pins, 3.5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid, 8–10 mm long, 4 mm diam., maturing red, drying black; persistent calyx 1–3 mm long, drying pale brown; seed dorsal surface with 4–5 deep irregular longitudinal furrows, the ventral surface with 2 irregular, incompletely divided longitudinal furrows.

Distribution (Fig. 36). Fairly widespread in Costa Rica, from upland Guanacaste to southeastern Limón, collected in tropical moist forest with equatorial to tropical-equatorial climate at elevations of 100 to 900 m. *Psychotria alfaroana* has been collected in flower January, March, June, and July, and in fruit July (immature), August, January, and February.

Selected specimens examined. COSTA RICA. ALAJUELA: 2 km N of Bijagua on trail to San Miguel, 7 km N of Río Naranjo, 400–500 m, 8 July 1976 (early fr), *J. Utley & K. Utley 5316* (DUKE). CARTAGO: vic. Psychotria alfaroana may be recognized by its suffruticose habit; leaves drying green; compact globose, pedunculate inflorescences with clustered secondary axes only 5–7 mm long; and large (8–10 × 4 mm) ellipsoid fruits usually drying black.

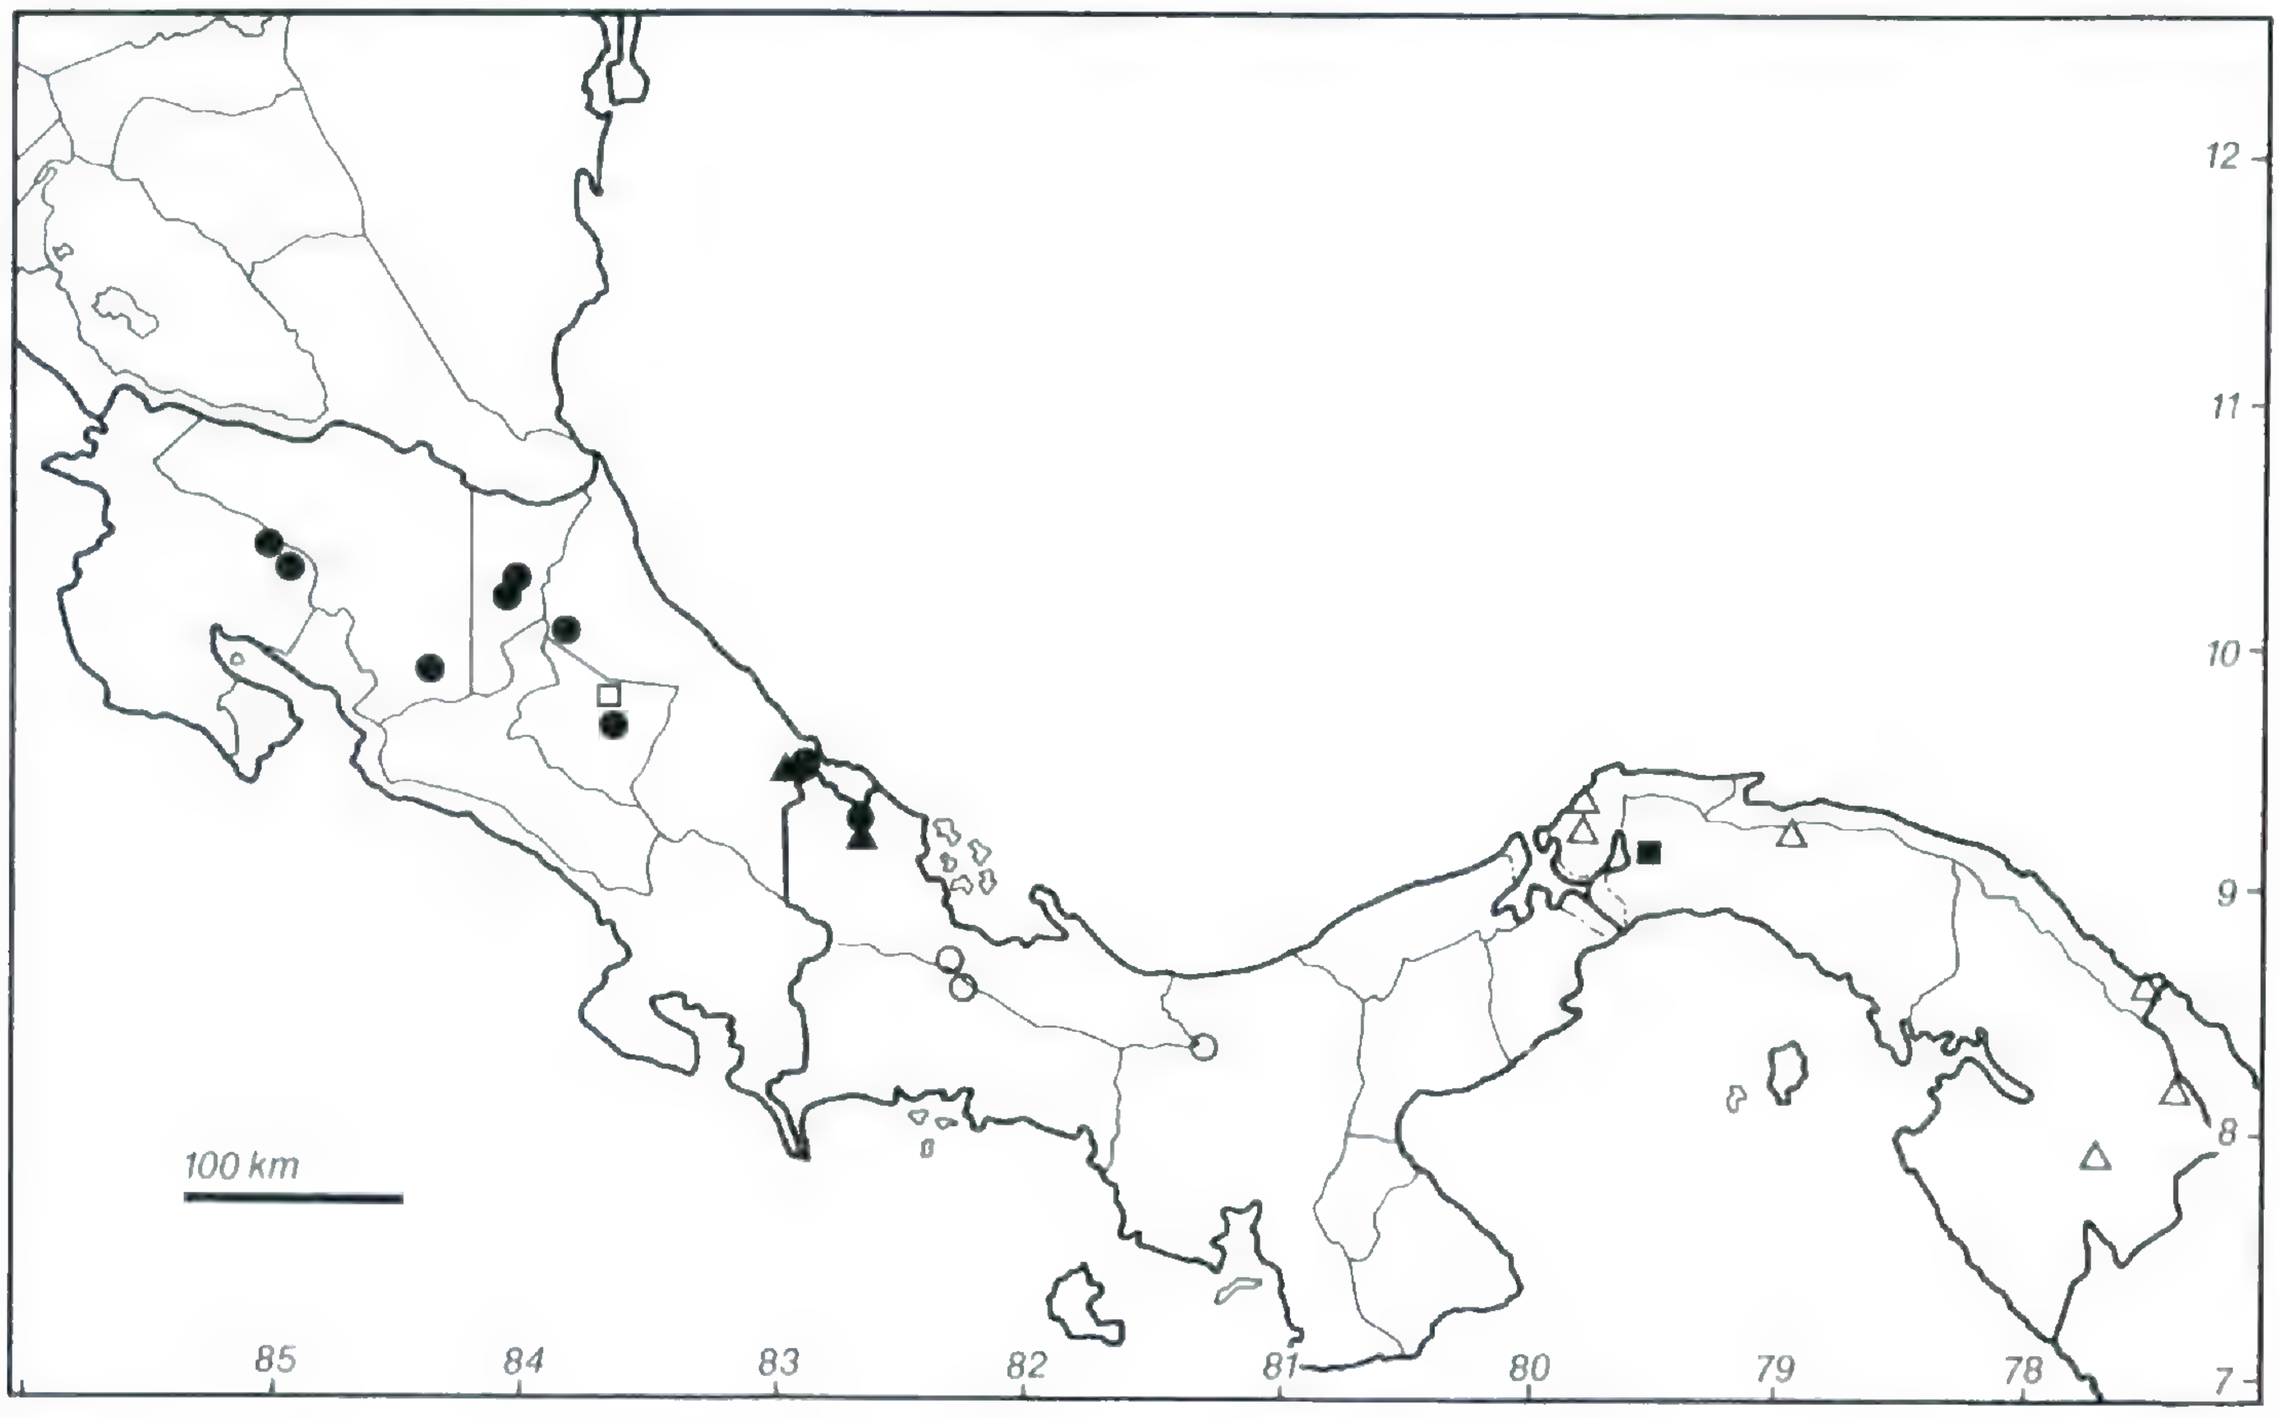

FIGURE 36. Distributions of *Psychotria alfaroana* (solid circles), *P. chitariana* (open square), *P. dressleri* (open triangles), *P. hammelii* (open circles), *P. pacorensis* (solid square), and *P. sixaolensis* (solid triangles).

The corolla tube of the pin morph appears conspicuously shorter (2.5 3 mm) than that of the thrum (3–4 mm).

51. Psychotria calophylla Standley, Contr. U.S. Natl. Herb. 18: 129. 1916. TYPE: Panama. Panamá: Chagres, Isthmus of Panama, 15 Mar. 1850 (early fr), *Fendler 60* (holotype, US; isotypes, GH, MO). Figures 3c, 34.

Psychotria cerroazulensis Dwyer, Ann. Missouri Bot. Gard. 53: 107. 1966. TYPE: Panama. Panamá: Cerro Azul, Goofy Lake area, 1 Sep. 1963 (fl), *Dwyer 2875* (holotype, MO).

Psychotria gatunensis Dwyer & Hayden, Ann. Missouri Bot. Gard. 54: 142. 1967. TYPE: Panama. Canal Area: area W of Limón Bay, Gatun Locks and Gatun Lake, 5 Aug. 1955 (early fr), *Johnston 1554* (holotype, MO; isotypes, A—2 sheets).

Psychotria grandicarpa Dwyer & Hayden, Ann. Missouri Bot. Gard. 55: 42. 1968. TYPE: Panama. Panamá: Cerro Jefe, 12 Mar. 1967 (fr), *Dwyer et al. 7244* (lectotype, MO 2002447, here designated; isolectotypes, MO—2 sheets).

Tree 3–8(–15) m tall; young stems brown-puberulent, the bark smooth; stipules ovate with irregular lobes and 2 aristate to narrow-triangular extensions 3–6 mm long, 8–15 × 5–15 mm, fringed, densely red-brown pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 1–3 cm long, red-brown pubescent, grooved above; blades membranous to subcoriaceous, elliptic to obovate, the apex acuminate, the base attenuate, (10–)13–26(–31) × 5–12 cm, glabrous above, red-brown tomentose to sometimes glabrous below, drying green-brown above and red-brown below; secondary veins (8–)10–15(–18) pairs, diverging 50°–75°, brochidodromous with collector vein undulate (Fig. 3c), constantly arcuate, elevated below, red-brown tomentose, the axils lacking domatia or hairs; tertiary veins inconspicuous to evident, orthogonal reticulate to percurrent. *Inflorescences* terminal, panicles of glomerules; panicle branched to 3(4) degrees; main axis 2.5–15 cm long, the peduncle lacking or 1.5–4.5 cm long; secondary axes in (2)3(4) ranks, the first-rank axes 2, 1.2–8 cm long, the second-rank axes 2, 0.6–4 cm long, the third-rank axes 2, 0.2 2.5 cm long, the fourth-rank axes 2, 0.7 1 cm long; bracts inconspicuous, triangular, 1 mm long, brown pubescent. *Flowers* sessile; calyx cup-shaped, the tube 1–2 mm long, the lobes 5, broad, barely evident, to 0.5 mm long, red-brown pubescent; corolla green-white, the tube cylindrical, 3.5–4 × 2–3 mm, very densely white pubescent in throat, puberulent without, the lobes 5(6), ovate to lanceolate, thickened apically, 2–2.5 × 0.7 mm; stamens 5(6), the filaments 2.5–3.5 mm long in pins,

4.5 mm long in thrums, the anthers 1–1.5 mm long; style 4–6 mm long in pins, 3 mm long in thrums, the branches linear or club-shaped. *Fruit* when dry ellipsoid, 10–14 mm long, 6–9 mm diam., maturing red, drying red-brown, sometimes red-brown puberulent; persistent calyx 2–3.5 mm long; seed dorsal surface with 4–5 longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 34). Known from southern Mexico and Izabal, Guatemala, and disjunct to Colón and Coclé to Panamá Province, Panama. This species is found at elevations of 30 to 1,000 m, mostly below 400 m, in tropical moist to premontane wet forest with equatorial to tropical climate. It has been collected in flower in March and May in Mexico and July–September and in December in Panama. Fruiting collections date from December in Guatemala and August and November–March in Panama.

Selected specimens examined. MEXICO. OAXACA: Mpio. Matías Romero, 3.2 km al SSO del Aserradero La Floresta, 16 km al S de Esmeralda, 17°03′N, 94°47′W, 300 m, 28 May 1981 (fl), *Hendt et al. 3332* (MEXU). VERACRUZ: Mpio. Hidalgotitlán, Río Solosuchil 5–6 km al ESE de Hermanos Cedillo, 150 m, 25 Mar. 1982 (fl), *Lorence et al. 3935* (MEXU). GUATEMALA. IZABAL: along Río Bonita, 30–150 m, 21 Dec. 1941 (fr), *Steyermark 41740* (A, F); along Río Tameja, 50 m, 24 Dec. 1941 (fr), *Steyermark 41785* (A, F); Cerro San Gil, 300–900 m, 25 Dec. 1941 (st), *Steyermark 41924* (F). PANAMA. CANAL AREA: Pipeline Road 5–10 mi. N of Gamboa, 21 Nov. 1971 (fr), *Gentry 2659* (GH, MO, NY); 11 Feb. 1974 (fr), *Nee 9600* (F, MO); nr. Piña, 0–100 m, 6 Dec. 1973 (fr), *Gentry & Nee 8721* (MO); Pipeline Road, 9°15′N, 79°45′W, 50 m, 10 Mar. 1983 (st), *Hamilton et al. 3255* (MO). COCLÉ: hills above El Valle, ca. 1,000 m, 24 Dec. 1972 (fr), *Gentry 6898* (F, GH, MO, NY). COLÓN: Miguel de la Borda, hill nr. beach, 24 Apr. 1970 (early fr), *Croat 10036* (F, MO—2 sheets); Río Guanche, 1–4 km upstream from Portobelo Road, 0–100 m, 10 Dec. 1973 (fr), *Gentry 8791* (MO—2 sheets); headwaters of Río Boqueron nr. fork with Río Nombre de Diosito, 150 m, 21 July 1978 (fl), *Hammel 3959* (MO); Salud, 50 m, 4 Aug. 1971 (fr), *Lao & Holdridge 207* (MO—2 sheets); Santa Rita Ridge rd., 10.2 km from Boyd–Roosevelt Hwy., 350 m, 15 Mar. 1975 (fr), *Mori & Kallunki 3065* (GH, MO); Río Guanche, 2.5 km upstream from bridge on Portobelo Road, 20 m, 27 Aug. 1975 (fl), *Mori & Witherspoon 7973* (MO, US). PANAMÁ: Cerro Azul, 23 Jan. 1967 (fr), *Duke 9363* (DUKE, MO); Cerro Jefe, to 850 m, 1 Jan. 1972 (early fr), *Gentry et al. 3513* (ENCB, MO, NY); El Llano Cartí rd., 9.6–11 km from Inter-American Hwy., 330–360 m, 4 Dec. 1974 (fr), *Mori & Kallunki 3528* (GH, MO).

The three species named from central Panama—*Psychotria cerroazulensis*, *P. gatunensis*, and *P. grandicarpa*—have morphologies well within the range of *P. calophylla* and are therefore included. One of the three specimens at MO of *Dwyer et al. 7244*, cited as the type of *P. grandicarpa*, is hereby chosen as the lectotype.

Psychotria calophylla may be recognized by its arborescent habit, large (usually 13–26 × 5–12 cm), elliptic to obovate leaves (these usually red-brown tomentose below), undulate collector vein, large panicles of glomerules with secondary axes usually in 3 ranks, and large (10–14 × 6–9 mm) ellipsoid fruits. Collections from Guatemala are noteworthy in that the leaf blades are obovate, as opposed to the more comon elliptic shape, and have fewer secondary veins than elsewhere in the range of the species.

52. Psychotria chitariana Dwyer & C. Hamilton in C. Hamilton, Phytologia 64: 221. 1988. TYPE: Costa Rica. Cartago: 13 km E of Turrialba, hwy. to Limón, canyon of Río Chitaría, 9°55′N, 83°36′W, 750–800 m, 10 May 1983 (fl), *Liesner et al. 15400* (holotype, MO; isotype, CR). Figure 36.

Shrub 1 m tall; young stems glabrous, the bark irregularly furrowed, with organic material accumulated in leaf axils; stipules not seen. *Leaves* petiolate; petioles ca. 1.5 cm long, glabrous, winged, flattened above; blades membranous to chartaceous, obovate, the apex rounded to obtuse, the base attenuate, 28–33 × 13–15 cm, glabrous above and below, drying pale brown to greenish red-brown; secondary veins 16–19 pairs, diverging (50°–)60°–65°(–70°), brochidodromous, straight to arcuate near margin, elevated below, glabrous, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate, the intersecondaries conspicuous. *Inflorescences* terminal, dense globose panicles of cymes; panicle branched to 3 degrees; main axis 7.5 cm long, the peduncle 4.5 cm long; secondary axes in 1 rank plus terminal cluster, the first-rank axes 2, 1 cm long, the clustered axes ca. 8, equal, 0.7–1 cm long; cymes branched to 1–2 degrees; bracts linear to triangular, 5 × 2.5 mm, glabrous. *Flowers* pedicellate, the pedicels 3–5 mm long; calyx cup-shaped, the tube 1 mm long, the lobes 5, barely evident, glabrous; corolla greenish white, the tube cylindrical, 4.5–5 × 1.5 mm, white pubescent in throat, the lobes 5, triangular, 2.3 × 1.5 mm; stamens 5, the filaments 4.5 mm long in pins, not seen in thrums, the anthers 1.5 mm long; style 7 mm long in pins, not seen in thrums, the branches minute. *Fruit* not seen.

Distribution (Fig. 36). Known only from the type collection from Cartago, Costa Rica, at 750–800 m in an area of premontane to lower montane

rainforest with equatorial-mountainous climate. *Psychotria chitariana* was collected in flower on May 10.

Psychotria chitariana may be recognized by its large (28–33 × 13–15 cm), obovate leaves with rounded to obtuse apex, and inflorescence secondary axes in one rank plus a terminal cluster.

The only flowering collection seen was a pin.

53. Psychotria dressleri (Dwyer) C. Hamilton, Phytologia 64: 223. 1988. *Cephaëlis dressleri* Dwyer, Ann. Missouri Bot. Gard. 67: 68, fig. 15. 1980. TYPE: Panama. San Blas: SE of Puerto Obaldía, 18 Aug. 1971 (fl), *Croat 16801* (holotype, MO). Figures 7d, 36.

Cephaëlis panchocoënsis Dwyer, Ann. Missouri Bot. Gard. 67: 78. 1980. TYPE: Panama. Darién: S slope of Cerro Tacarcuna above Río Pucro base camp, 700 1,000 m, 25 Jan. 1974, *Gentry & Mori 13895* (holotype, MO, n.v.).

Shrub or subshrub 0.2 1.5 m tall; young stems glabrous, the bark irregularly fissured and fluted, with organic material accumulated in leaf axils; stipules sheathing, slightly cleft at apex, 17–26 × 8 10 mm, glabrous, caducous, leaving a pale ridge with interrupted red-brown fringe. *Leaves* sessile to subsessile; petioles to 1 cm long; blades membranous, obovate, the apex acuminate to cuspidate, the base attenuate, (13–)20–47 × (8–)10–24 cm, glabrous above and below, drying red-brown to green-brown, paler below; secondary veins 17–25 pairs, diverging 50°–70°, eucamptodromous to brochidodromous, straight to slightly arcuate toward margin, elevated below, red-brown puberulent below, the axils lacking domatia or hairs; tertiary veins very conspicuous, orthogonal reticulate, the percurrent tertiaries especially prominent, the looping tertiaries between the secondary loops and the margin also prominent. *Inflorescences* terminal, panicles of glomerules; panicle branched to 2–3 degrees; main axis 2–9 cm long, the peduncle (0.5–)1.5–5 cm long; secondary axes in 1 2 ranks or clustered (Fig. 7d), the first-rank axes 2 or 4, the longer pair 0.5 1.5 cm long, the shorter pair when present 0.5–0.7 cm long, the second-rank axes 2 or 4, the longer pair 0.5 cm long, the shorter pair when present 0.2 cm long; bracts and bracteoles spathulate, 10 15 × 6–8 mm, glabrous. *Flowers* sessile; calyx cup-shaped, the tube 2 mm long, the lobes 5, linear, 1.5–2 × 0.8 mm, fringed; corolla white, the tube cylindrical, 10–12 × 1–2 mm, white pubescent in tube in zone ca. 8 mm from base, the lobes 5, linear with apical appendage 1 mm long, 2 3 × 1 mm; stamens 5, the filaments 10 mm long in pins, 13–14 mm long in thrums, the anthers 2.5 mm long; style 14 mm long in pins, 8–10 mm long in thrums, the branches linear, puberulent. *Fruit* when dry ellipsoid, 8–9 mm long, 3.5–4.5 mm diam., maturing color unknown, when dry deep red-brown; calyx persistent, 1–3 mm long; seed dorsal surface with 3–4 deep longitudinal furrows, the ventral surface with 2 incompletely divided longitudinal furrows.

Distribution (Fig. 36). Known only from eastern Panama near the ridge running along the Caribbean coast south to Cerro Pirre at elevations of 20–1,000 m and across the border into Colombia in tropical wet to premontane wet forest with equatorial-mountainous to equatorial-tropical climate. *Psychotria dressleri* has been collected in flower January–August, and in fruit August–December and March.

Additional specimens examined. PANAMA. COLÓN: Santa Rita lumber road, nr. Aqua Clara rain gauge, 26 July 1974 (fl), *Dressler 4677* (MO—2 sheets); Santa Rita Ridge, ca. 12 km from Transisthmian Hwy., 28 June 1978 (early fr), *Hammel 3665* (MO); Río Guanche, 2.5 km upstream from bridge on rd. to Portobelo, 20 m, 27 Aug. 1975 (fr), *Mori & Witherspoon 7954* (MO); along banks of Río Guanche, above bridge, 50 m, 8 July 1976 (fl), *G. Sullivan 183* (MO). DARIÉN: La Boca de Pirre, 13 Oct. 1967 (early fr), *Bristan 1277* (MO); trail from Tacarcuna Village on Río Tacarcuna to Cerro Malí, 800 1,300 m, 16 Jan. 1974 (fl), *Gentry 13598* (MO); Serranía del Darién, trail from Cerro Malí to Río Pucro camp, 20 July 1976 (fl), *Gentry et al. 16826* (MO). PANAMÁ: El Llano–Cartí Rd., 4 mi. beyond hwy., 500 m, 5 Dec. 1979 (fr), *Croat 49145* (MO).

Material annotated *Cephaëlis panchocoënsis* by Dr. Dwyer does not differ substantially from *P. dressleri* and is therefore included.

Psychotria dressleri may be recognized by its large (usually 20–47 × 10 24 cm), obovate leaves with organic material accumulated in the leaf axils and by its contracted (2–9 cm long) panicles of glomerules with clustered secondary axes and enlarged (10–15 × 6–8 mm) spathulate bracts.

54. Psychotria hammelii Dwyer, Ann. Missouri Bot. Gard. 67: 383, fig. 72. 1980. TYPE: Panama. Veraguas: mountains W of Alto de Piedras W of Santa Fe, 960–1,680 m, 8 Sep. 1978 (early fr), *Hammel 4634* (holotype, MO—2680614; isotype, MO—2806155). Figure 36.

Herb or subshrub 0.1 0.3 m tall, stoloniferous; young stems glabrous, angled, the bark smooth; stipules sheathing, bifurcate, often split down center, 15 22 × 5–10 mm, glabrous, caducous, per-

sistent at top 3–5 nodes, leaving a red-brown ridge. *Leaves* petiolate; petioles 7–18 mm long, glabrous, grooved above; blades membranous, bullate, elliptic, the apex cuspidate, the base narrowly cuneate, (5–)8–12 × (2–)3–4.5 cm, glabrous above, puberulent on veins below, drying deep red-brown; secondary veins 11–15 pairs, diverging (45°–)60°–70°, eucamptodromous, constantly arcuate, elevated below, red-brown puberulent below, the axils lacking domatia or hairs; tertiary veins conspicuous, orthogonal reticulate. *Inflorescences* terminal, panicles of cymes; panicle branched to 3 degrees; main axis 4–4.5 cm long, the peduncle 1.5–3 cm long; secondary axes in 2 ranks, the first-rank axes 2, 1.2–1.3 cm long, the second-rank axes 2, 0.4–0.5 cm long; cymes branched to 1 degree; bracts linear, 8–9 × 3 mm, glabrous. *Flowers* pedicellate, the pedicels ca. 1 mm long; calyx cylindrical, the tube 1–2 mm long, the lobes 5, linear, 1–2 × 0.7 mm, glabrous, fringed; corolla white, the tube cylindrical, 4 × 1.5 mm, white pubescent in throat, the lobes 5, ovate with apical extension 0.5 mm long, 1 × 0.7 mm; stamens 5, the filaments 3 mm long in pins, not seen in thrums, the anthers 1 mm long; style 5 mm long in pins, not seen in thrums, the branches linear. *Fruit* when dry ellipsoid, 5–7 mm long, 3.5–4 mm diam., maturing red, drying deep red-brown; persistent calyx 1–2 mm long; seed dorsal surface with 4 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 36). Known only from the western cordillera in Panama at ca. 1,000 m elevation in low montane wet forest to rainforest with equatorial-mountainous climate. This species has been collected in flower in March and June–July, in fruit in April, and with immature fruit in June and September.

Additional specimens examined. PANAMA. BOCAS DEL TORO: E slope of La Zorra, 19 Apr. 1968 (fr), *Kirkbride & Duke 812* (MO—2 sheets). CHIRIQUÍ: vic. Gualaca ca. 8.5 mi. from Planes de Hornito, La Fortuna, 1,300 m, 10 July 1980 (fl), *Antonio 5060* (MO); behind Vivero Forestal de Boquete, 12 km N of Los Planes de Hornito, IRHE Fortuna Hydroelectric Project, 8°43′N, 82°14′W, 1,100–1,200 m, 17 June 1982 (fl, early fr), *Knapp & Vodicka 5538* (MO); Qda. de Arena, N of Carretera de Oleoducto, IRHE Fortuna Hydroelectric Project, 8°46′N, 82°12′W, 1,100 m, 12 Mar. 1982 (fl), *Knapp et al. 4083* (MO).

Psychotria hammelii may be recognized immediately by its bullate leaves, small (4–4.5 cm long) panicles of cymes with enlarged bracts, and ellipsoid fruits with conspicuous persistent calyx.

The only two flowering collections seen are of the pin morph.

55. Psychotria insignis Standley, Contr. U.S. Natl. Herb. 18: 130. 1916. Not *Ixora insignis* (Muell. Arg.) Kuntze (based on *Rudgea insignis* Muell. Arg. in Martius). TYPE of *P. insignis*: Panama. San Blas: hills of Sperdi, nr. Puerto Obaldía, 20–200 m, Sep. 1911 (fl), *Pittier 4410* (holotype, US; isotype, F). Figure 35.

Shrub; young stems densely ferrugineous-pubescent; stipules ovate, 12 × 4 mm, ferrugineous-pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 2.5–5.5 cm long, ferrugineous-pubescent, perfectly terete or often grooved above; blades membranous, ovate, the apex acuminate to cuspidate, the base cordate, 14–22 × 7–10 cm, glabrous above except for the adaxially puberulent midvein, ferrugineous-pubescent below, drying deep red-brown; secondary veins 17–20 pairs, diverging 100°–105°, brochidodromous with collector vein undulating near margin, constantly arcuate, elevated and densely pubescent below, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate to percurrent. *Inflorescences* terminal, panicles of glomerules; panicle branched to 3–4 degrees; main axis 2.5 cm long, the peduncle lacking; secondary axes in 1 rank, the first-rank axes 1–2, 1.5 cm long; bracts triangular, 2–2.5 mm long, 5 mm across, ferrugineous-pubescent and fringed. *Flowers* sessile; calyx cylindrical, the tube 1 mm long, the lobes 5, linear, 1–1.2 × 0.8 mm, red-brown puberulent; mature corolla, stamens, and style not seen. *Fruit* not seen.

Distribution (Fig. 35). Known only from the type collection from near Puerto Obaldía, San Blas, Panama, at ca. 100 m elevation in tropical moist forest with tropical-subtropical climate. It was collected in flower in September.

Psychotria insignis may be recognized immediately by its large (14–22 × 7–10 cm) ovate leaves with bases cordate and drying deep red-brown, numerous (17–20) secondary veins diverging 100°–105°, and by small (2.5 cm long) ferrugineous-pubescent panicles of glomerules.

56. Psychotria insueta (Dwyer) C. Hamilton, Phytologia 64: 226. 1988. *Cephaëlis insueta* Dwyer, Ann. Missouri Bot. Gard. 67: 73. 1980. TYPE: Panama. Veraguas: 11 km from

Escuela Agricola Alto de Piedra, along Río Dos Bocas, Atlantic slope, 15 Nov. 1974 (early fr), *Mori & Kallunki 3108* (holotype, MO). Figure 35.

Shrub 0.4–1.7 m tall; young stems glabrous to minutely puberulent, the bark furrowed longitudinally, with organic material accumulated in leaf axils; stipules with a sheath 9 mm long and with 2 linear extensions 2 mm long, minutely fringed, caducous, leaving a red-brown ridge without fringe. *Leaves* sessile; blades membranous, obovate to oblanceolate, the apex cuspidate, the base decurrent, 30 42 × 8–19 cm, glabrous above and below, drying dull green or brown-green above, paler dull green below; secondary veins 34–42 pairs, diverging 75°–110° with higher angles toward base, brochidodromous, the collector vein straight along margin, constantly arcuate, elevated below, glabrous, axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate to percurrent. *Inflorescences* terminal, rounded-umbellate panicles of cymes; panicle branched to 4 degrees; main axis 17–18 cm long, the peduncle 3.5–7 cm long; secondary axes in 4 ranks, the first-rank axes 2, 9 cm long, the second-rank axes 2(3), 3–4.5 cm long, the third-rank axes 2, 2–2.5 cm long, the fourth-rank axes 2, 0.7–1 cm long; cymes branched to 3 degrees; bracts subtending branches, broad irregular, 1 mm long, irregularly fringed. *Flowers* pedicellate, the pedicels 0.5–1.5 mm long; calyx cup-shaped, the tube 1–1.5 mm, the lobes 5, barely evident to none, with pubescent fringe; corolla white, the tube cylindrical, 2 × 1.5 mm, white pubescent in throat, the lobes 5, linear, 2 × 1 mm; stamens 4, the filaments 2 mm long in pins, not seen in thrums, the anthers 1 mm long; style 3.5 4 mm long in pins, not seen in thrums, the branches spathulate. *Fruit* ellipsoid when dry, 7–10 mm long, 4–5 mm diam., maturing blackish (?), drying black; persistent calyx a beak to 0.5 mm long; seed dorsal surface with 5 longitudinal furrows, the ventral surface with 2 incompletely divided longitudinal furrows appearing as 1 furrow.

Distribution (Fig. 35). Known only from the continental divide north of El Copé, Coclé, Panama, at ca. 750 m and north down to ca. 200 m elevation, and from the Atlantic slope in Veraguas; it is found in tropical wet to premontane rainforest with equatorial-mountainous climate. This species has been collected in flower on June 21 and in fruit October–November.

Additional specimens examined. PANAMA. COCLÉ: El Copé, on Pacific side, half-hour walk from sawmill, 780 m, 16 Oct. 1979 (fr), *Antonio 2090* (MO); nr. Aserradero El Copé, N of El Copé, second stream E of sawmill, 700–750 m, 2 Nov. 1980 (fr), *Dressler 5964* (MO); E of El Copé sawmill, along stream, ca. 660 m, 21 June 1978 (fl), *Hammel 3595* (MO). VERAGUAS: trail from Coquyito mine to Río Barrera junction with Río Concepción, 150–300 m, 17 Oct. 1978 (early fr), *Hammel 5227* (MO).

Psychotria insueta may be recognized by its large (30–42 × 8–19 cm), glabrous, obovate to oblanceolate leaves with many (34–42) secondary veins diverging 75°–110° and joining in a collector vein; large (17–18 cm long) panicles of cymes; and ellipsoid fruits drying black.

The only flowering collection seen is a pin morph.

57. Psychotria monteverdensis Dwyer & C. Hamilton in C. Hamilton, Phytologia 64: 230. 1988. TYPE: Costa Rica. Guanacaste-Puntarenas: al oeste de Reserva de Monteverde, 1,520–1,590 m, 24 June 1977 (fl), *Dryer 1531* (holotype, MO; isotype, CR). Figure 35.

Shrub 2.5 m tall; young stems glabrous, the bark irregularly furrowed longitudinally; stipules sheathing, truncate with 2 aristate appendages 2 mm long from apical corners, 7–8 × 4 mm, glabrous, caducous, leaving a pale ridge with long red-brown fringe. *Leaves* sessile to petiolate; petioles to 0.5 cm long, glabrous, grooved above; blades subcoriaceous, elliptic, the apex acuminate, the base cuneate, (9–)13–15 × (2–)3–4.5 cm, glabrous above and below, drying pale green-brown; secondary veins 9–11 pairs, diverging 45°–60°, brochidodromous with collector vein undulating near margin, constantly arcuate, prominent below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal, few-branched panicles of glomerules; panicle branched to 2 degrees; main axis 3.6 cm long, peduncle 2.4 cm long; secondary axes in 2 ranks, the first-rank axes 2, 0.6–0.7 cm long, the second-rank axes 2, reduced; bracts linear, 8 mm long, ciliate; bracteoles ovate, 3–4 mm long, ciliate. *Flowers* sessile or with pedicels to 1.5 mm long; calyx cup-shaped, the tube ca. 1 mm long, the lobes 5, triangular to lanceolate, to 1 mm long, ciliate; corolla green-yellow, leathery, the tube cylindrical, 3 × 2 mm, pubescent in throat, the lobes 5, triangular with robust keel-like appendages, 2 × 1 mm; stamens 5, the filaments 2.5 mm long, the anthers 1.2 mm long; style 4 mm long, the branches clublike. *Fruit* not seen.

Distribution (Fig. 35). Known only from the type collection from near the Monteverde Reserve

near the Guanacaste Puntarenas border, Costa Rica, at ca. 1,550 m elevation in low montane wet forest with equatorial-mountainous climate. *Psychotria monteverdensis* was collected in flower on June 24.

Psychotria monteverdensis may be recognized by its subcoriaceous medium-sized (usually 13–15 × 3 4.5 cm) leaves with collector vein, small (3.6 cm long) inflorescences with secondary axes 2 per rank in 2 ranks, those of the second rank sessile, and leathery greenish corollas with keel-like abaxial appendages on the lobes.

Only one flower was dissected, but the minute separation (0.3 mm) between stigma and anthers suggests that the species is long-homostylous.

58. Psychotria pacorensis C. Hamilton, Phytologia 64: 232. 1988. TYPE: Panama. Panamá: vic. Cerro Jefe, Altos de Pacora, 720 m, 18 Dec. 1980 (early fr), *Antonio 3241* (holotype, MO; isotype, ENCB). Figure 36.

Shrub 2–3 m tall; young stems minutely red-brown puberulent, the bark longitudinally grooved and fluted; stipules ovate, 10 × 4 mm, glabrous, caducous, leaving a red-brown ridge with or without fringe. *Leaves* petiolate; petioles 5–13 mm long, glabrous, grooved above; blades membranous, elliptic to obovate, the apex acute to caudate, the base cuneate, (13–)16 25 × (4)5–10 cm, glabrous above, glabrous below except on veins, drying red-brown, paler below; secondary veins 12 14 pairs, diverging 70° 80°, eucamptodromous to brochidodromous, constantly arcuate, elevated and minutely puberulent below, the axils lacking domatia or hairs; tertiary veins conspicuous, orthogonal reticulate, the percurrent tertiaries especially conspicuous, the tertiary arches near margin numerous. *Inflorescences* terminal, panicles of cymes; panicle branched to 3 degrees; main axis 4.5 cm long, the peduncle 3.5 cm long; secondary axes in 3 ranks, the first-rank axes 4, the longer pair 0.5 0.6 cm long, the shorter pair 0.3 cm long, the second-rank axes 4, the longer pair 0.2 0.3 cm long, the shorter pair reduced, the third-rank axes 2, 0.2 cm long; cymes branched to 1–2 degrees; bracts and bracteoles broad, to 1 mm long, fringed. *Flowers* sessile to pedicellate, the pedicels to 2 mm long; mature flowers not seen. *Fruit* when dry ellipsoid, 5.5–7 mm long, 3.5 5 mm diam., maturing purple, drying red-brown; persistent calyx cup ca. 0.5 mm long; seed dorsal surface with 4-5 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 36). Known only from the Altos de Pacora region near Cerro Azul and Cerro Jefe, eastern Panamá Province, Panama, at ca. 750 m elevation in premontane wet forest with tropical-equatorial climate. *Psychotria pacorensis* has been collected with immature fruit in December and in fruit in February.

Additional specimens examined. PANAMA. PANAMÁ: Cerro Jefe, 6 mi. past Cerro Azul on rd. to Altos de Pacora, 780 m, 19 Feb. 1981 (fr), *Sytsma & D'Arcy 3689* (MO -2 sheets).

Psychotria pacorensis may be recognized by its large (usually 16–25 × 5–10 cm) leaves drying red-brown and with brochidodromous veins with secondary loops (not marginal collector vein) and conspicuous tertiary veins including numerous arches between the secondaries and the margin.

59. Psychotria psychotriifolia (Seemann) Standley, Contr. U.S. Natl. Herb. 18: 133. 1916. *Cephaëlis psychotriifolia* Seem., Bot. Voy. Herald: 138. 1854. *Uragoga psychotriifolia* (Seem.) Kuntze, Revis. Gen. Pl. 2: 962. 1891. *Psychotria psychotriaefolia* auctt. TYPE: Panama: *Seemann 182* (holotype, BM, n.v., photo, MO). Figures 2g, 35.

Psychotria sinuensis Standley, Publ. Field Columbian Mus., Bot. Ser. 7: 114. 1930. TYPE: Colombia. Bolívar: Boca Verde, on Río Sinu, 4 Mar. 1918 (fl), *Pennell 4572* (holotype, NY).

Shrub 0.5–2 m tall; young stems ferrugineous-pubescent, the bark smooth; stipules with a sheath 8–13 × 4–5 mm, truncate, biaristate with the extensions 1.5–4 mm long from apical corners (Fig. 2g), glabrous to ferrugineous-pubescent, caducous, often persistent at terminal 3 5 nodes, leaving a ridge. *Leaves* petiolate; petioles 2–15 mm long, ferrugineous-pubescent, grooved above; blades membranous, oblanceolate to elliptic, the apex acute, the base attenuate or subcordate, (5.5–)7.5 17(–20) × (1.5)3 6.5(8) cm, glabrous above, glabrous to red-brown puberulent below, the midvein puberulent, drying green-brown to red-brown, paler below; secondary veins (10)14 20(23) pairs, diverging 70° 85°, brochidodromous, with collector vein almost parallel near margin, constantly arcuate, prominulous below, puberulent below, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules; panicle branched to 2(3) degrees; main axis 8–17 mm long, the peduncle absent; secondary axes in 1–2(–3) ranks, the first-rank axes 2

or 4(6), equal, 0.8–2 cm long, the second-rank axes 2 or 4, equal, 0.5–1 cm long; bracts sheathing, biaristate, 3–5 mm long, glabrous to puberulent; bracteoles subtending glomerules enlarged, cuplike, 3–4 mm long, glabrous to puberulent. *Flowers* sessile; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, lanceolate, 1 × 0.7 mm, puberulent, ciliate; corolla green-white, the tube cylindrical, 1.5 × 1–1.5 mm, white pubescent in throat, the lobes 5, lanceolate with minute apical appendage, 1 × 0.6 mm; stamens 5, the filaments 1.5 mm long in pins, 2–2.5 mm long in thrums, the anthers 0.5–0.7 mm long; style 2.5–3 mm long in pins, 1.3 2 mm long in thrums, the branches short. *Fruit* narrow-ellipsoid when dry, 5 6 mm long, 3–4 mm diam., maturing red, drying red-brown; persistent calyx conspicuous, tubular, 0.5 2 mm long; seed dorsal surface with (4)5 longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 35). Known from southern Nicaragua through Panama, with very discontinuous distribution, at 0–800 m elevation in tropical moist to premontane wet forest with equatorial to tropical climate. This species occurs also in Colombia, Venezuela, and Ecuador. It has been collected in flower and in fruit throughout the year.

Selected specimens examined. NICARAGUA. RIVAS: N de Volcán Concepción, Isla de Ometepe, 11°32′N, 85°38′W, 800–1,000 m, 7 Aug. 1982 (fr), *Sandino 3469* (MO). The original spelling "*psychotriaefolia*" has been corrected to "*psychotriifolia*" in accordance with the International Code of Botanical Nomenclature (Article 73.8).

Psychotria psychotriifolia may be recognized by its oblanceolate to elliptic leaves drying green-brown to red-brown with collector vein near margin, epedunculate inflorescences with enlarged cup-like bracts subtending the ultimate glomerules, and narrowly ellipsoid (5–6 × 3 4 mm) fruits with conspicuous persistent calyx tube.

60. Psychotria rosulatifolia Dwyer, Ann. Missouri Bot. Gard. 67: 423, fig. 77. TYPE: Panama. Darién: trail from Río Pucro base camp up W ridge of Cerro Malí, 640 1,000 m, 6 Feb. 1975 (fr), *Gentry & Mori 14174* (holotype, MO). Figure 35.

Subshrub or herb 0.5 m tall; young stems glabrous or puberulent, the bark irregularly furrowed; stipules sheathing, ovate, often split down center, 15–20 × 6–7 mm, glabrous, caducous, leaving a red-brown ridge. *Leaves* sessile; blades membranous, lanceolate, the apex caudate, the base sagittate, 16–28 × 4.5–8.5 cm, glabrous above and below, drying deep red-brown or sometimes green-brown; secondary veins 27–32 pairs, diverging

80°–95°, brochidodromous with collector vein near margin, constantly arcuate, elevated below, glabrous or red-brown puberulent below, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate to percurrent. *Inflorescences* terminal, spreading panicles of cymes; panicle branched to 4 degrees, the axes delicate; main axis 8–13 cm long, the peduncle 2.5 6.5 cm long; secondary axes in 3 ranks, the first-rank axes 2, 2.5–4 cm long, the second-rank axes 2 or 4, the longer pair 1–2 cm long, the shorter pair when present 1 -1.2 cm long, the third-rank axes 2, 0.5 0.9 cm long; cymes branched to 1–2(–3) degrees; bracts linear, 4 mm long, glabrous; bracteoles triangular, to 1.2 mm long, glabrous. *Flowers* pedicellate, the pedicels 1–2 mm long; calyx cup-shaped, the tube 0.5–0.7 mm long, the lobes 5, often barely evident, triangular, to 0.2 mm long, glabrous; corolla white, the tube narrow-cylindrical, 2.5–4 × 1.2 mm, white pubescent in throat, the lobes 5, linear with 1-mm-long extension from apex, not spreading, 2.5–4 × 1 mm; stamens 5, the filaments 2 mm long in pins, not seen in thrums, the anthers narrow, 2 mm long; style 6 mm long in pins, not seen in thrums, the branches clublike. *Fruit* ellipsoid when dry, 5–6 mm long, 4–4.5 mm diam., maturing red, drying red-brown; persistent calyx a beak ca. 0.5 mm long; seed dorsal surface with 5 deep longitudinal furrows, the ventral surface with 2 barely evident longitudinal furrows.

Distribution (Fig. 35). Known only from the regions of Cerro Pirre and Cerro Malí, eastern Darién, Panama, at ca. 700 1,300 m elevation in premontane to low montane rainforest with equatorial-mountainous climate. *Psychotria rosulatifolia* has been collected in flower in April, July, and August, and in fruit in August, November, and February.

Additional specimens examined. PANAMA. DARIÉN: Cerro Pirre, 11 Apr. 1967 (fl), *Bristan 515* (MO); ascent of Cerro Pirre, Río Pirre, S of El Real, 750 1,030 m, 11 Aug. 1962 (fl, early fr), *Duke 5339* (MO); Cerro Pirre, 750 1,350 m, 9 10 Aug. 1969 (fl, fr), *Duke & Elias 13788* (MO); Cerro Pirre, ridgetop nr. Rancho Plastico, 1,200 m, 10–20 July 1977 (fl), *Folsom 4295* (MO); Cerro Pirre, valley between Pirre and next most southerly peak, 10 20 July 1977 (fl), *Folsom 4428* (MO); top of ridge leading to Cerro Pirre, nr. Rancho Plastico, 1,200–1,400 m, 13 Nov. 1977 (fr), *Folsom et al. 6285* (MO).

Psychotria rosulatifolia may be recognized by its large (16–28 × 4.5–8.5 cm), sessile, oblanceolate leaves with 27–32 secondary veins plus a collector vein; delicate panicles of cymes; flower buds appearing narrow and acuminate due to narrow 1-mm-long apical extensions from corolla lobes; and medium-sized (5–6 × 4–4.5 mm), ellipsoid fruits.

Five pin and no thrum collections suggest strongly that *Psychotria rosulatifolia* is pin-monomorphic.

61. Psychotria sixaolensis C. Hamilton, Phytologia 64: 234. 1988. TYPE: Costa Rica. Limón: rd. between Limón and Shiroles, Río Sixaola, 0.9 mi. SW of Bambu, 6.5 mi. SW of Bribrí, 0 50 m, 12 Aug. 1977 (fr), *Croat 43303* (holotype, MO). Figure 36.

Shrub or subshrub to 1.5 m tall; young stems ferrugineous-pubescent; stipules sheathing, ovate, 10 × 6 mm, ferrugineous-pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 1–3.5 cm long, red-brown puberulent, grooved above; blades membranous, elliptic to obovate, the apex acuminate, the base attenuate, (14)16–30 × (5.5–)8–13 cm, glabrous above, sparsely red-brown tomentose below, the midvein more densely tomentose, drying red-brown; secondary veins (20–)25–35 pairs, diverging 75°–80°, brochidodromous with collector vein near margin, constantly arcuate, elevated below, red-brown tomentose below, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules; panicle branched to 2–3 degrees; main axis in fruit 9.5–15 cm long, the peduncle in fruit 7.5 13.5 cm long; secondary axes in 2 ranks, the first-rank axes 2, 1.5–2 cm long, the second-rank axes 2, 0.5 cm long; bracts and bracteoles ovate, 7 × 6 mm, ferrugineous-pubescent. *Flowers* sessile; calyx cup-shaped, the tube 1–2 mm long, the lobes 5, linear, 2–3 × 0.8 mm, ferrugineous-pubescent; corolla white, the tube cylindrical, 4 × 2.5 mm, white pubescent in throat, the lobes 5, ovate with blunt robust protuberance from near apex, 3 × 1.5 mm; stamens 5, the filaments 3 mm long in pins, not seen in thrums, the anthers 1.3 mm long; style ca. 6 mm long in pins, not seen in thrums, the branches linear. *Fruit* ellipsoid when dry, 7 9 mm long, 5 mm diam., drying red-brown; persistent calyx 2 3 mm long; seed dorsal surface with 4 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 36). Known from southeastern Limón, Costa Rica, and Bocas del Toro, Panama, at 0–50 m elevation in tropical moist forest with equatorial-tropical climate. This species

has been collected in flower in April, in mature fruit in August.

Additional specimens examined. COSTA RICA. LIMÓN: nr. Río Sixaola, ca. 0.5 mi. SW of Bambu, ca. 3 mi. NE of Bratsi, 15 m, 12 Aug. 1977 (early fr), *Croat 43250* (CR, MO). PANAMA. BOCAS DEL TORO: Río Teribe between Qda. Treglo and Puerto Palenque, 2 Apr. 1968 (fl, early fr), *Kirkbride & Duke 536* (MO—2 sheets).

Psychotria sixaolensis may be recognized by its ferrugineous aspect, large (usually 16–30 × 8–13 cm) leaves with usually 25–35 secondary veins and a collector vein, and long-pedunculate panicles of glomerules with large (7 × 6 mm) ovate bracts.

The lone flowering collection seen is a pin morph.

EXCLUDED TAXA

Psychotria microdon (A. P. de Candolle) Urban, Symb. Antill. 9: 539. 1928. *Rondeletia microdon* DC., Prodr. 4: 408. 1830. *Mapouria microdon* (DC.) Bremek., Recueil Trav. Bot. Néerl. 31: 286. 1934.

Psychotria pinularis Sessé & Mociño, Fl. Mexic. ed. 2, 57. 1894.

Steyermark (Mem. New York Bot. Gard. 23: 446–447. 1972) included this species in subgenus *Psychotria*, from which it differs, however, in having leaves drying pale green, a seed cross-section with only a central keel on the dorsal surface (vs. several longitudinal furrows), marcescent stipule remnants persisting at the nodes, and lateral branches in opposite pairs (vs. diverging singly from a main axis). This species does not appear closely related to any neotropical members of *P.* subg. *Heteropsychotria* Steyerm., either. Instead, the above character states plus the leaf secondary veins arching broadly toward the margin suggest affinity with African *P.* subg. *Tetramerae* (Hiern) E. Petit, many species of which have bacterial "nodules" on the leaf undersides (Petit, Bull. Jard. Bot. État 34: 1–229, 1964; 36: 65–190, 1966). *Psychotria microdon* and *P. nutans* Sw. may be the sole neotropical species—aside from *P. punctata* Vatke, introduced in Florida—of that subgenus.

APPENDIX I. Numerical list of taxa.

Group 1

1. *Psychotria carthagenensis* Jacq.
2. *P. clivorum* Standl. & Steyerm.
3. *P. lamarinensis* C. Hamilton
4. *P. micrantha* Kunth
5. *P. neillii* C. Hamilton & Dwyer
6. *P. quinqueradiata* Polak.
7. *P. viridis* Ruiz & Pavón

Group 2

NOTES

NOTES ON ARACEAE

Anthurium iramirezae Bunting, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Depto. Río Negro, Serranía de Tapirapeco: afloramiento de roca granítica, 1°20′N, 64°55′W, 1,350 m, 25 Mar. 1988, *I. Ramírez & L. Laskowsky 310* (holotype, VEN). Figure 1A, B.

Herba perennis ca. 75 cm alta. Caulis horizontalis brevis crassusque. Petioli subteretes sed adaxialiter canaliculati, 19–40 cm longi. Foliorum laminae cartilagineae, ovatae, 30–37 cm longae (petiolos subaequantes vel eis usque ad duplo longiores), 19–24 cm latae, basi non profunde cordatae sinu plus minusve arcuato 1.0–1.7 cm profundo, apice breviter acuminatae, abaxialiter sparsim obscureque fusco-punctatae, nervis lateralibus primariis utrinque ca. 7 sub angulo 45–55° ex costa oreuntibus. Pedunculi 45–71 cm longi. Spathae anguste oblongo-ovatae, usque ad 11 cm longae, in sicco 1.8 cm latae, basi decurrentes per 0.8 cm, recurvatae vel reflexae, virides, persistentes. Spadices atropurpurei, 13.3–15.3 cm longi, sessiles sed axe antice nudo.

Perennial herb ca. 75 cm tall. Stem horizontal, thick, with very short internodes, some dry cataphyll remains, and few leaves. Petioles subterete but adaxially canaliculate, the canal narrower than petiole width and with rounded margins, 19–40 cm long; geniculum 1.7–2.3 cm long, 1.0–1.2 cm thick. Leaf blades nearly erect on petiole, cartilaginous (drying stiff), ovate, 30–37 cm long (subequaling or to twice as long as petioles), 19–24 cm wide (1.5–1.7 times longer than wide), basally shallowly cordate with sinus 1.0–1.7 cm deep, apically obtuse and briefly acuminate ending in a cusp to 1.3 cm long, adaxially glossy, abaxially sparsely and obscurely brown-punctate; midrib and all veins prominently elevated; primary lateral veins 7(–8) arising from each side of midrib at angles of 45–55° and running to margins; lesser veins forming a rather fine reticulum prominent on both faces; lowermost primaries not naked in sinuses. Peduncles solitary, 45–71 cm long. Spathes narrowly oblong-ovate, to 11 cm long (including 8-mm-long slender tip), drying 1.8 cm wide, basally decurrent for 0.8 cm, recurved or reflexed, green, persistent. Spadices cylindric, 13.3–15.3 cm long, 0.75 cm thick, dark purple becoming green in age, exceeding 1.5 cm thick in fruit, sessile but axis naked on front for 0.8 cm, with 6–8 flowers visible in the principal spiral. Fruits unknown.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: same locality as type collection, *Ramírez & Laskowsky 318* (VEN).

This species is closely related to *Anthurium guanchezii* Bunting but differs by having a cartilaginous leaf blade not basally stipitate, the lowermost primary lateral veins not naked in the basal sinus, a proportionally narrower spathe, and a nonstipitate spadix. In *A. guanchezii* Bunting, the blade is pergameneous or semicoriaceous, and the spathe is 3.6 times longer than broad. Additionally, *A. iramirezae* grows at an altitude of 1,350 m on granitic outcrops with thin soil and woody vegetation to 10 m tall, whereas *A. guanchezii* occurs in moist forests at 120 m altitude some 500 km to the north.

From *A. wurdackii* Bunting, the new species differs by having leaf blades that tend to be ovate and proportionally broader with an arcuate basal sinus, while the peduncle is shorter and the base of the spathe is more shortly decurrent. In *A. wurdackii*, the leaf blade is often elliptic-ovate, about 1.9 times longer than wide with an angular basal sinus, and the spathe is decurrent for 3.5–7.5 cm. Further, the leaf blade of *A. wurdackii* apparently lacks abaxial, dark punctations such as occur in *A. iramirezae*.

The species is named in honor of a collector of the type material, Ivón Ramírez, a young Venezuelan botanist who also successfully introduced it into cultivation. I observed the plant in Maracay, Venezuela, among a collection of unusual Venezuelan aroids and other plants growing at the family home of her husband, Germán Carnevali.

Philodendron triplum Bunting, sp. nov. TYPE: Venezuela. Edo. Bolívar: carretera El Dorado–Santa Elena de Uairén, en aprox. km 120 al sur de El Dorado, en bosque al lado de la vía, 1,200 m, 22 Feb. 1968, *G. S. Bunting 3102* (holotype, NY; isotype, MY). Figure 1C.

Herba perennis subrosulata. Caulis brevis validusque cataphyllorum reliquiis fibrosis ferrugineis tectus. Petioli abaxialiter rotundati superficie adaxiali late sed leviter concava, usque ad 19 cm longi. Foliorum laminae subcoriaceae, oblongae, usque ad 58 cm longae, 16.5 cm latae, basi rotundatae sinu acuto 1 cm profundo, apice acutae vel obtusae et breviter acuminatae, nervis later-

A

B

C

alibus primariis utrinque 9–11 sub angulo 55–65° ex costa abeuntibus. Inflorescentia ignota.

Subrosulate, perennial herb. Stem short, stout, with accumulated, rust-colored, fibrous cataphyll remains. Petioles abaxially rounded, with adaxial face broadly but shallowly concave, to 19 cm long. Leaf blades subcoriaceous, oblong, to 58 cm long (3 times longer than petioles), 16.5 cm wide (ca. 3.5 times longer than wide), at base rounded and notched (1 cm deep), at apex acute or obtuse and briefly acuminate; primary lateral veins 9–11 arising from each side of midrib at angles of 55–65°, with some secondary lateral veins manifest. Inflorescence unknown.

The type collection was taken from a plant growing as an epiphyte 2 m above the ground; it is not certain that it represents the fully mature adult phase of this species. A similar though somewhat less adult plant, collected in the same area as the type, has recently been seen in cultivation at the family home of Lic. Germán Carnevali in Maracay, Venezuela. A juvenile specimen, *Bunting 2916* (MY), collected in the same sector at km 126 south of El Dorado, Bolívar, Venezuela, apparently pertains to this taxon. It has leaves of similar form, texture, and color, but, as is typical of juvenile shoots, has a more slender stem with elongate internodes and has wide-winged petioles basally encircling the stem and sheathed up to the base of the blade.

This species differs from *Philodendron melinonii* Brongn. ex Regel by the proportionally shorter petioles and narrower leaf blades. In *P. melinonii*, the blade length is 1.4 times longer than the petiole and 1.5–2.4 times longer than wide.

The specific epithet reflects the fact that the leaf blade is three times longer than the petiole and more than three times longer than wide.

I am grateful to Lic. Germán Carnevali and his wife, Sra. Ivón Ramírez de Carnevali, for making available dried and living specimens of the aroids collected by them during recent botanical explorations. My appreciation is expressed to the Director and personnel of the Herbario Nacional (VEN), Jardín Botánico, Caracas, for the loan of herbarium material.

—George S. Bunting, *101 Linden Ave., Pocomoke City, Maryland 21851, U.S.A.*

HOSTA JONESII (LILIACEAE/FUNKIACEAE), A NEW SPECIES FROM KOREA

Hosta Tratt. is an economically important genus of approximately 22–25 species restricted to eastern Asia. *Hosta* has been placed in the Liliaceae (Cronquist, 1981; Hutchinson, 1964) or Funkiaceae (Dahlgren et al., 1985). Bailey (1930), Stearn (1931), and Hylander (1954) all pointed out that the major difficulty with the classification of the *Hosta* lies in the uncertainty regarding criteria for delimiting the species. The taxonomic difficulties have been attributed to relatively few diagnostic characters (Fujita, 1976), the extreme difference in appearance between living plants and dried herbarium specimens (Hylander, 1954), and possible widespread hybridization (Maekawa, 1940). Thus the treatment of species within *Hosta* has varied depending on authors. For example, Maekawa (1969) described several new species but combined others recognized in his 1940 treatment. Fujita (1976) noted that Maekawa (1940, 1969) did not consider the variability of natural populations when developing his classification. Fujita recognized only 15 species as native to Japan, while Maekawa (1969) had recognized 25 species there. Although Fujita carefully described morphological characters and ecological and geographical distribution, his studies were confined to Japan.

In 1985, 1987, and 1988, I conducted field trips to collect hostas from natural populations in Korea and on Tsushima Island of Japan in order to understand better the variation patterns. While visiting several islands off the coast of southern Korea, I encountered a morphologically distinct group of *Hosta* populations not referable to any described species of *Hosta*. The herbaria at Seoul National University (SNU), Tokyo University (TI), and Kyoto University (KYO) were visited and there were several undetermined specimens of this group collected by Young Chung (SNU) and one specimen collected by T. Nakai (TI). Loans were examined from BH, BM, E, K, L, and PE, but no herbarium specimens of the group were encountered. This series of populations is a new species as described below.

Hosta jonesii M. Chung, sp. nov. [subgen. *Bryocles* (Salisb.) F. Maekawa sect. *Tarthanthae* (F. Maekawa) F. Maekawa]. TYPE: KOREA: Kyeongsang Nam Do, Namhae Gun, Sangju Myeon, Namhae Island, Mt. Kumsan, N 13 mi. ascent from Yangha Ri. Among rocky and humus soil on south-facing slope, shade, ca. 250 m, common, 28 Aug. 1988, *M. G. Chung & M. S. Chung 1613* (holotype, GA). Figure 1.

Rhizoma breve repens. Folia erecto-patentia; laminae elliptico-lanceolatae vel anguste ovatae, 6–13 cm longae 3–5 cm latae, obtusae vel breviter acuminatae in apice, leviter angustatae in base, distincte petiolatae, supra atro-virentes vel viridulae, utrinque 5–7 nervatae, nervis infra paullo laevibus; petioli 4.5 13 cm longi 4–7 mm lati. Scapi oblique ascendentes, 35–60 cm longi 2–4 mm lati, in infera parte purpureo-punctati, teretes; inflorescentia ca. 15 cm longa (1–)3–20 florifera, bracteis acutis, navicularibus, viridibus, clausis. Infra inflorescentiam bracteae ascendentes, lanceolatae, 15–40 mm longae 4–20 mm latae. Pedicelli ascendentes, 4 8 mm longi, albo-virentes, minute purpureo-punctati. Alabastra viridescentia. Perianthia 40–50 mm longa, ca. 25 mm in diametro; pars inferior tuborum angustiorum saepe albescens; pars superior tuborum dilatatorum paullo campanulata, dilute purpurea; nervi interiores leviter colorati; lobi oblongi, acuti, 13 15 mm longi 7 8 mm lati. Stamina 39 48 mm longa, fere aequilonga corollae; antherae ca. 3 mm longae subflavescenti-purpureae. Pistillum 45–52 mm longum.

Herbaceous perennials from short, creeping rhizomes. Leaves erect-patent, spirally arranged at the base of stem; petioles 4.5–13 cm long, 4–7 mm wide, dotted with purple, slightly winged; blades elliptic-lanceolate or narrowly ovate, 6–13 cm long, 3–5 cm wide, dark dull green, slightly rigid, obtuse or acuminate at the apex, gradually narrowed at the base into the petioles, the nerves of upper leaf surface inconspicuous when fresh, nearly glabrous on the 5–7 pairs of somewhat smooth, not-elevated nerves of lower leaf surface, margins thinly white-lined. Scapes obliquely ascending, terete, 35–60 cm long, 2–4 mm wide, dotted with purple dots basally, usually with 2 lanceolate bracts below inflorescence, these 15–40 mm long, 4–20 mm wide; bracts within inflorescence acute, navicular, green, 8–13 mm long, 3–4 mm wide, not open at flowering, relatively persistent after flowering; pedicels obliquely ascending, 4–8 mm long, whitish green, minutely purple-dotted, usually shorter than the subtending bracts. Perianths 40–50 mm long, ca.

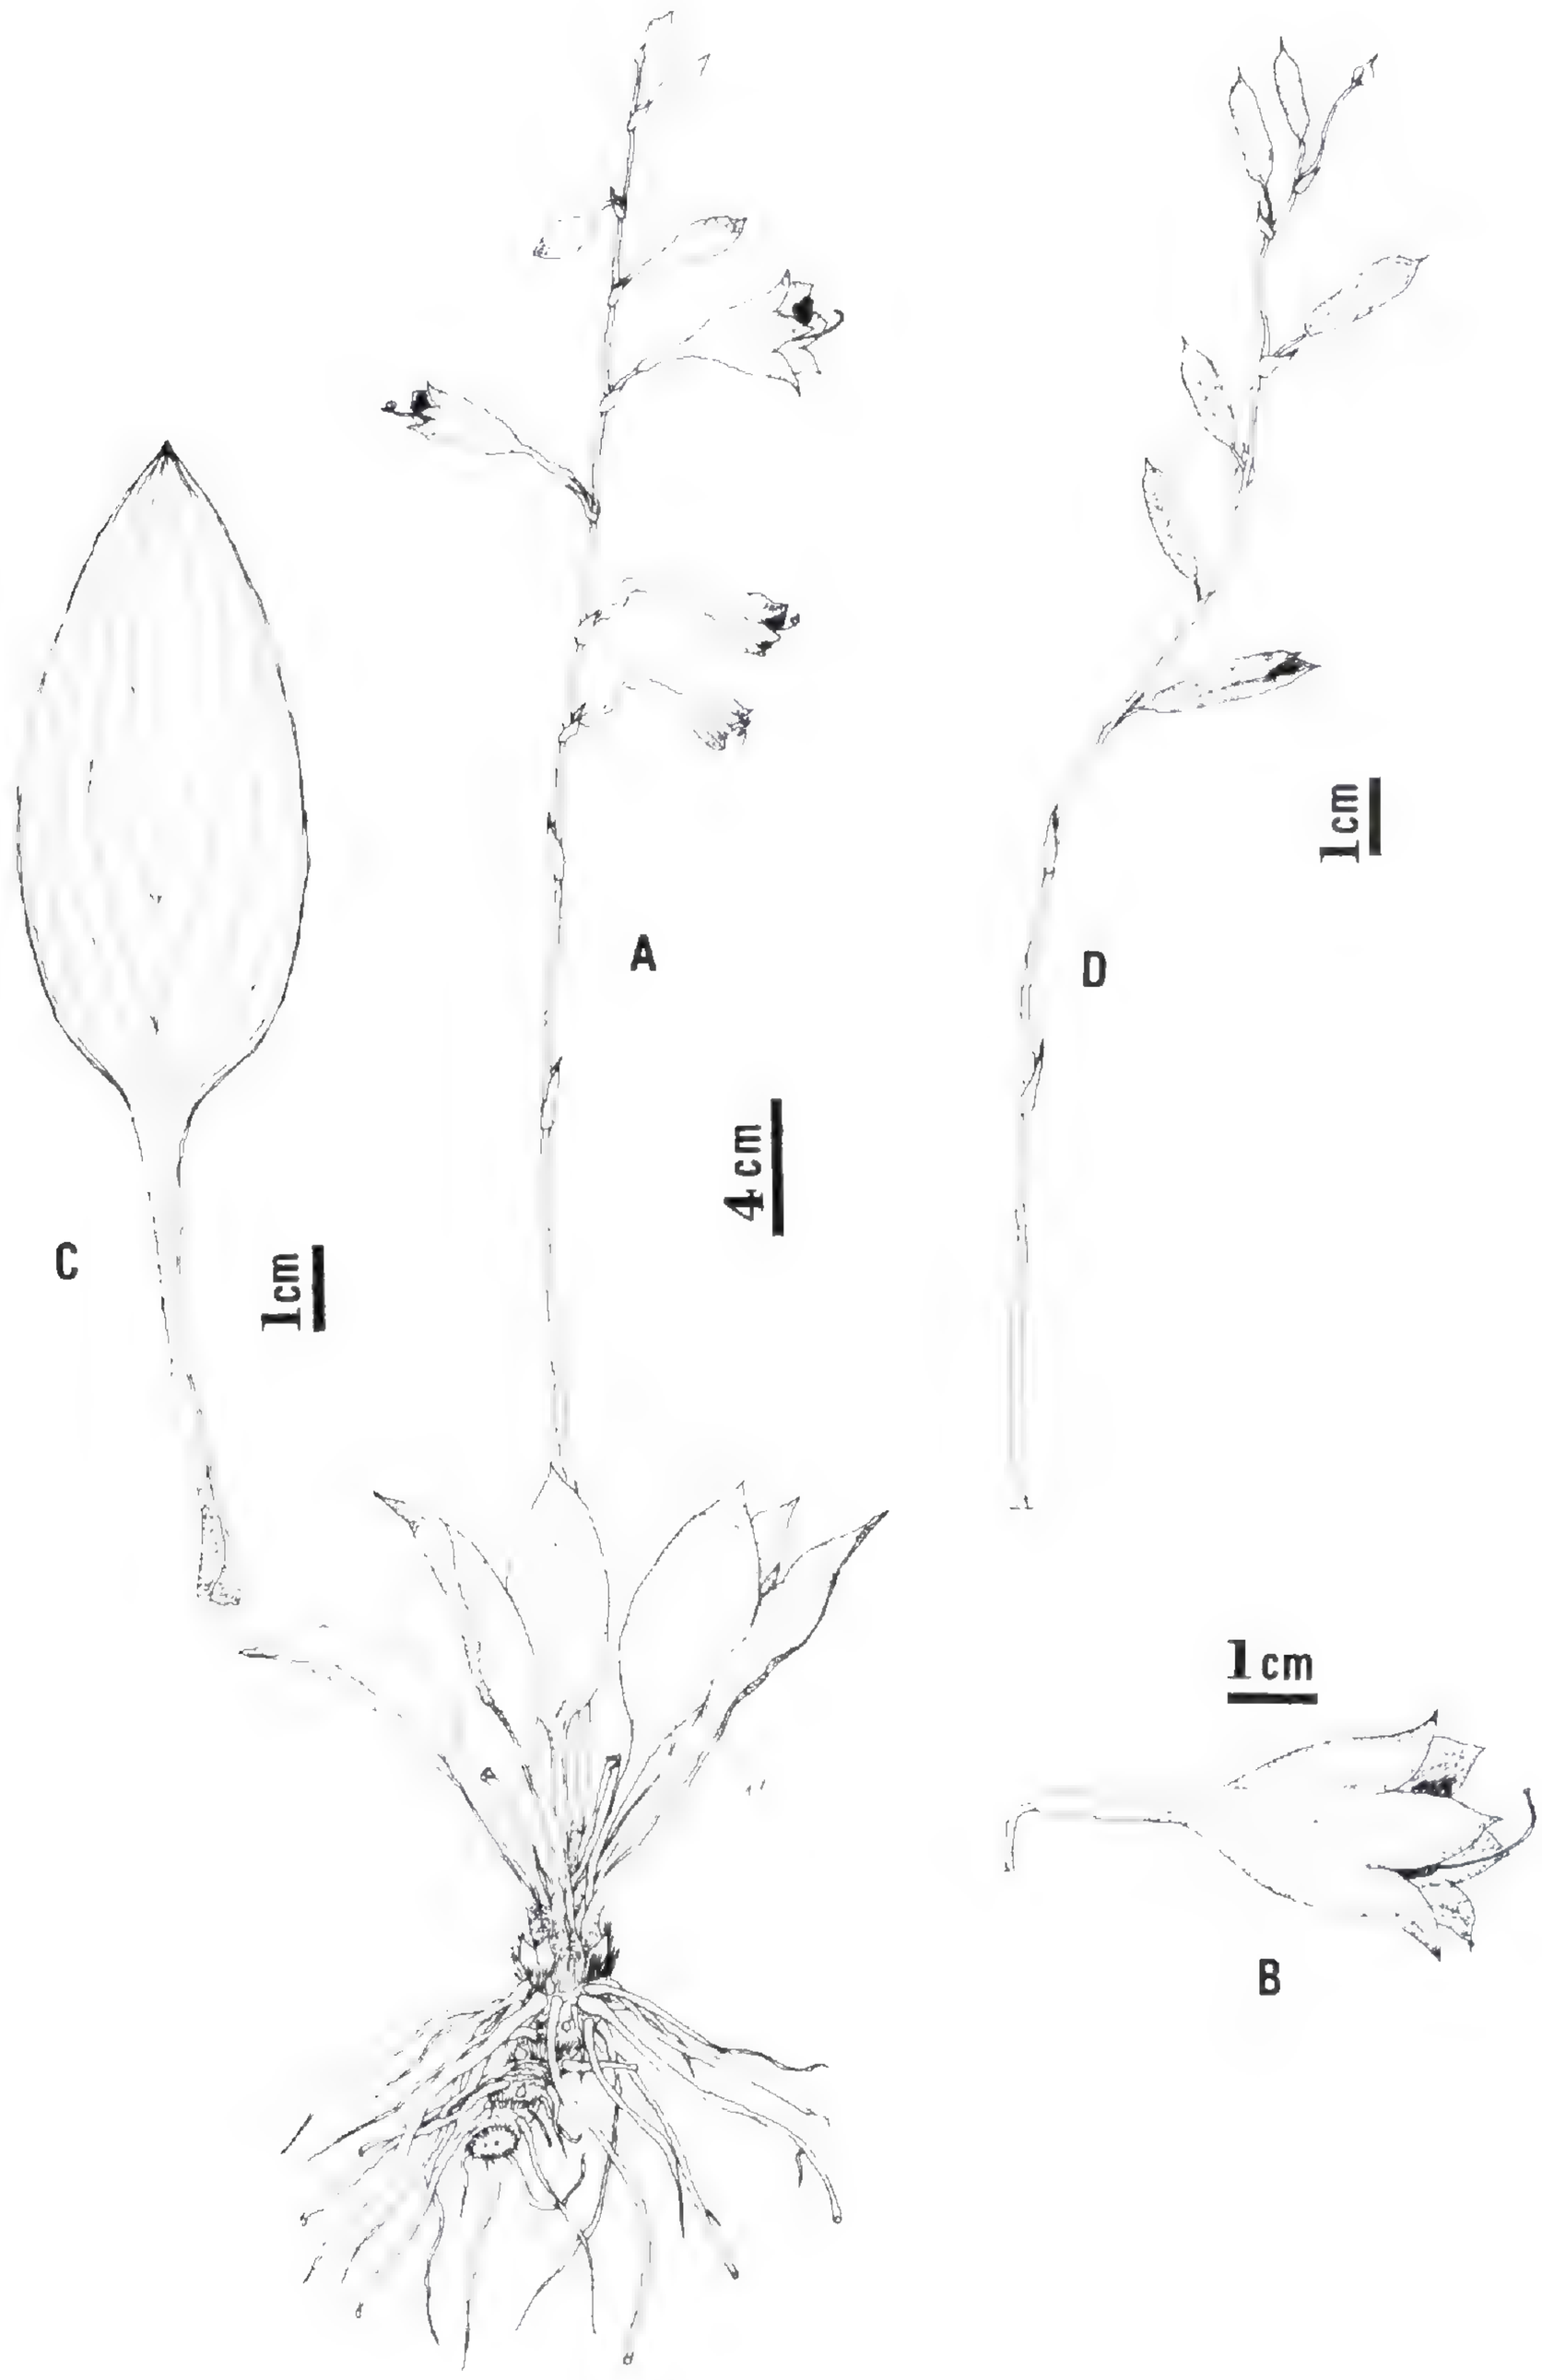

FIGURE 1. *Hosta jonesii* (A–C, holotype).—A. Habit. -B. Flower viewed from the side.—C. Leaf, adaxial surface. -D. Fruits on the obliquely ascending scape.

25 mm diam., about (1–)3 20 flowers on each raceme, whitish purple, greenish in bud; the basal narrower portion of perianth tubes whitish; the upper dilated portion of perianth tube somewhat bell-shaped; the inner nerves not intensely colored; lobes oblong, acute, 13–15 mm long, 7–8 mm wide; 6 translucent lines originating from the dividing parts of the lobes extend to the middle of lower narrower perianth tube; stamens 39–48 mm long, nearly equal to or longer than perianth; anther ca. 3 mm long, yellowish purple. Pistil 45–52 mm long. Capsule cylindric, 22–33 mm long, 4–6 mm wide. Flowering in mid August to early September.

Korean name. Tadohae-bibich'u.

Paratypes. KOREA: Kyeongsang Nam Do, Namhae Gun, Namhae Island; Mt. Kumsan, *Y. Chung s.n.* (NA);

Cholla Nam Do, Yoch'on Gun, Dolsan Island, *M. Chung 957* (GA); *S. Lee 101* (GA), *103* (KYO), *106* (MO), *107* (SNU), *112* (TI). Each collection from shade of pine–oak forest on rocky and rich humus soil near ocean.

Hosta jonesii is distinguished from other species of *Hosta* by the navicular, green, persistent bracts; thick, adaxially dark dull green leaves; and white-lined leaf margins. This species appears to be related to *H. minor* (Baker) Nakai by the shape of bracts and perianths and by the creeping rhizomes. It differs by the terete scapes, elliptic-lanceolate leaf blades, and flowering period from middle August to early September. *Hosta minor* flowers in mid July to early August and is endemic to southeastern Korea, including Wando and Kojae islands. The new taxon also is very close to *H. tsushimensis* N. Fujita (Fujita, pers. comm., 1988) but differs by having short creeping rhizomes; longer perianth lobes; upper dilated portions of perianth tubes bell-shaped; whitish purple inner perianth nerves; scapes dotted basally with purple; thinly white-lined leaf margins; somewhat smooth, not-elevated nerves of lower leaf surfaces; and thick, dark dull green leaves. *Hosta yingeri* S. B. Jones is distinct from *H. jonesii* by having ovate, adaxially lustrous leaves; delicate raceme of flowers spread around the central axis of the inflorescence; decurrent, flat bracts; relatively longer pedicels; and distinct, exserted 3+3 stamens.

The new species is named in honor of Dr. Samuel B. Jones, who has provided encouragement with my studies of *Hosta*. I thank Dr. Richard A. LaFleur for correcting the Latin description and Nancy C. Coile for comments on this manuscript. I also thank Dr. N. Fujita, Dr. H. Obha, and Mr. Haynes Currie for discussions on the classification of *Hosta*. Special thanks go to my parents, Mun Su and Jeom Ryo Chung, my wife, Min Suk Chung, Mr. Jong Sae Son, Seok Myeon Lee, and Chin Seop Hwang for their company on field trips. Gratitude is due the directors and curators of BH, BM, E, GA, K, KYO, L, PE, SNU, TI, and US.

A NEW SPECIES OF *ALLOMARKGRAFIA* (APOCYNACEAE) AND NOTES ON THE GENUS

Allomarkgrafia laxiflora A. Gentry, sp. nov. TYPE: Colombia. Nariño: Tumaco Tuquerres road, W of Junín, 900 m, tropical pluvial forest, 25 Nov. 1981, *A. Gentry, C. Barbosa, E. Barrera, C. Bonifaz, H. Cuadros, L. Quiñones, E. Renteria & D. Sanchez 34939* (holotype, COL; isotypes, COL, MO).

Frutex scandens, glaber. Folia anguste oblonga, acuminata, coriacea, prope basin supra glandulifera. Inflorescentia laxa. Flores calyce 5-lobato, corolla infundibuliformi, parte superiore anguste campanulata, parte basali tubulosa, intra pilosa infra insertionem antherarum sagittatarum. Fructus linearis, 31–35 cm longus, ca. 2 mm latus.

Vine, stems terete, glabrous, drying dark with pale lenticels. Leaves very narrowly oblong, acuminate, cuneate at base, 7–13 × 1.5–2.8 cm, coriaceous, completely glabrous, the secondary and tertiary venation not evident, glandular adaxially at base of midvein, the petiole 0.5–0.8 cm long. Inflorescence axillary, open, dichotomously branched, the dichotomies subtended by minute triangular bracts. Calyx lobes round-tipped, 1–2 mm long; corolla pale yellow, narrowly campanulate above a narrowly tubular base, constricted at intersection of upper and lower tubes at level of stamen insertion, glabrous outside, inside densely pilose in upper half of lower part of tube, the base plus upper tube ca. 2.5 cm long, the lobes round, ca. 5 mm long, glabrous outside; filaments pilose, 1 mm long, the anthers sagittate, connivent, 5 mm long, the obtuse basal auricles ca. 1 mm long, the thin apical connective ca. 1 mm long; gynoecium 2 mm long, glabrous, apocarpous. Follicles paired, long and narrow, glabrous, 31 35 cm long, terete and ca. 2 mm wide before dehiscing, flat and to 5 mm wide when dehisced, the seeds narrow, acute, 5–6 mm long, with a dense apical tuft of tan trichomes to 3 cm long.

Although this distinctive new species resembles species of *Mandevilla*, it belongs to *Allomarkgrafia*, which differs from *Mandevilla* primarily in the paniculately branched inflorescence. However, this species is not at all close to *A. plumeriiflora* Woods., with which it was first identified. Among the obvious features differentiating *A. laxiflora* from *A. plumeriiflora* are the very openly branched inflorescences with small bracts, very differently shaped, narrower flowers, and narrower leaves.

Allomarkgrafia laxiflora is probably more closely related to *A. foreroi* A. Gentry and *A. ovalis* (Mgf.) Woodson, both of which occur in Chocó, Colombia, and both of which have similar laxly branching inflorescences. The new species differs vegetatively from both of these species in having very obscure leaf venation like that of *A. plumeriiflora*. The distinctive corolla shape of *A. laxiflora* likewise helps separate it from its two probable closest relatives. In *A. ovalis* the corolla is broadly (vs. narrowly) infundibuliform-campanulate above

FIGURE 1. *Allomarkgrafia laxiflora* (*Gentry et al. 34939*).

the basal tube, and in *A. foreroi* it is more narrowly campanulate above the basal tube, which is longer and narrower than that of the new species. *Allomarkgrafia foreroi* differs further from *A. laxiflora* in having slender, more tenuous inflorescence branches; longer, thinner calyx lobes; and differently colored flowers (white with upper tube greenish and lower tube reddish).

There are only two other *Allomarkgrafia* species in addition to those discussed above: Peruvian *A. tubiflora* Woodson ex Dwyer has leaves like *A. ovalis* and a longer campanulate upper corolla tube much like that of many Bignoniaceae, while Costa Rican *A. brenesiana* Woods. has white flowers with a gradually and narrowly infundibuliform upper part of the corolla tube. Another Costa Rican species described by Woodson is conspecific with *A. plumeriiflora*.

Thus from a bitypic genus (Woodson, 1933) *Allomarkgrafia* has now grown to six species. As currently known, it is strongly Chocó-centered, with four out of the six species occurring in trans-Andean Colombia: *Allomarkgrafia laxiflora* and *A. foreroi* are endemic to Chocó; *A. ovalis* is wide-ranging from Amazonian Peru to Panama; and *A. plumeriiflora* ranges from trans-Andean Colombia to Nicaragua. The two localized outliers are *A. brenesiana* at middle elevations in Costa Rica and *A. tubiflora* in upper Amazonian Peru (900–950 m).

The species of *Allomarkgrafia* may be separated by the following key:

1a. Inflorescence closely branching with strongly ascending, crowded, conspicuously bracteate branches; corolla tube base with conspicuous medial or submedial swelling; flowers shorter than 3 cm, the upper tube broadly infundibuliform ..... *A. plumeriiflora*

1b. Inflorescence laxly branching with small, inconspicuous bracts (reduced to 2–3 few-flowered branches in *A. tubiflora*); corolla tube base lacking prominent swelling; flowers longer than 3 cm, the upper tube campanulate or narrowly infundibuliform.

2a. Corolla tube very gradually narrowly infundibuliform above the narrow basal part; Costa Rica above 1,000 m ..... *A. brenesiana*

2b. Corolla tube abruptly campanulate above the narrow basal part; South America to Panama, below 1,000 m.

3a. Leaves broadly elliptic to oblong, the finely parallel tertiary venation conspicuous; base of corolla tube much shorter than campanulate to obconical upper part.

4a. Upper part of corolla tube broadly infundibuliform-campanulate, the mouth 2–3 cm across ..... *A. ovalis*

4b. Upper part of corolla tube campanulate, the mouth less than 1.5 cm across ..... *A. tubiflora*

3b. Leaves narrowly to very narrowly oblong or elliptic, the tertiary venation inconspicuous or not evident; base of corolla tube longer than narrowly campanulate upper part.

5a. Leaves abruptly acuminate, coriaceous, the secondary and tertiary venation not visible or very obscure below; young branchlets drying dark with light lenticels; inflorescences ca. twice branched, the branches drying black or dark brown; basal part of corolla tube pilose inside in upper half ..... *A. laxiflora*

5b. Leaves tapering gradually to long acumen, chartaceous, the secondary and tertiary veins not pronounced but clearly visible below; young branchlets drying light with dark lenticels; inflorescences 3–4 times dichotomous, the branches drying light brownish; basal part of corolla tube pilose inside only near apex ..... *A. foreroi*

CHROMOSOME NUMBER IN *WALLERIA* (TECOPHILAEACEAE)

The small African genus *Walleria*, comprising three species (Carter, 1962), is generally considered to be allied to the Lilialean family Tecophilaeaceae. The five core genera of Tecophilaeaceae, *Tecophilaea*, *Zephyra*, and *Conanthera* (all Chilean), *Odontostomum* (Californian), and *Cyanella* (southern African), are small seasonal perennials united by their tunicate cormous rootstock, basally clustered leaves, racemose inflorescences, and flowers with poricidal anthers, partly inferior ovary, and subulate style with a punctiform stigma. In addition, the pollen grains have an operculate sulcus and tectate-columellate ektexine (Simpson, 1985), and the smooth seeds have a multilayered testa with a black, phytomelan-encrusted outer layer. As treated by Hutchinson (1934), the first modern phylogenist to recognize the family, Tecophilaeaceae also included the African *Cyanastrum*, now generally treated as the sole genus of Cyanastraceae (Dahlgren et al., 1985; Simpson, 1985). In 1959 Hutchinson transferred *Walleria* to Tecophilaeaceae from Liliaceae–Dianelleae (Hutchinson, 1934). Dahlgren et al. (1985: 165) accepted *Walleria* in Tecophilaeaceae with reservations; Dahlgren & van Wyk (1988) concluded that it did belong in the family, although they placed it in its own subfamily, Wallerioideae.

Walleria is discordant in Tecophilaeaceae for several reasons. The rootstock is a fleshy naked tuber, the leaves are cauline (not basal), the inflorescence is foliose, and the ovary is completely superior. Also, the seeds are warty and dark brown, not smooth and black, and it is uncertain whether they contain phytomelan (Dahlgren & van Wyk, 1988), although this is said to be absent by Huber (1969). Simpson (1985) demonstrated that the pollen grains of *Walleria* resemble those of other Tecophilaeaceae in having a medial apertural operculate sulcus and an endexinous basal layer of the operculum and aperture border. Although the operculum of *Walleria* differs from other Tecophilaeaceae in being very scanty and in having a granular (vs. tectate-columellate) ektexine, its basic structural similarity with that of the core genera of the family supports inclusion of *Walleria* there (Simpson, 1985). Embryologically, *Walleria* differs in having mostly campylotropous ovules (anatropous in other Tecophilaeaceae) and a large embryo (Dahlgren & van Wyk, 1988). With this background in mind, we undertook this investigation of the chromosome number in the two tropical African members of the genus, previously unknown cytologically.

Materials and Methods

Root tips were harvested at mid-morning from greenhouse-grown wild-collected material, tubers of *W. mackenzii* and seeds of *W. nutans*. The tips were placed in saturated aqueous mono-bromonaphthalene, and left at room temperature for four hours before fixation in 3 : 1 absolute ethanol glacial acetic acid for two minutes. After hydrolysis in 10% HCl for six minutes at 60°C, the apical portions of the tips were squashed in FLP orcein (Jackson, 1972).

Voucher data are as follows:

Walleria nutans Kirk—Namibia. Gobabis: Steinhausen road, *Goldblatt & Manning 8802* (MO).

W. mackenzii Kirk—Malawi, Zomba district, near Thondwe village, *Goldbatt 7519* (MO).

Observations and Discussion

The diploid chromosome number in both species of *Walleria* examined is $2n = 24$. The chromosomes are of moderate size, 2–4 μm in the method used. The chromosomes are mostly acrocentric but four of the smaller pairs are sub-metacentric.

Basic chromosome number in Tecophilaeaceae is probably $x = 12$ (Ornduff, 1979; Goldblatt, 1980). *Cyanella* has predominantly $n = 12$ or 24, although a population of *C. hyacinthoides* has $n = 14$, and one population of *C. lutea* has $n = 8$ (Ornduff, 1979). Of the New World genera examined cytologically, *Tecophilaea* has $n = 12$ (La Cour, 1955) and *Odontostomum* $n = 10$ (Cave, 1949, 1970). The chromosome cytology of *Walleria* thus accords well with Tecophilaeaceae and, viewed in conjunction with data reviewed above, supports its placement here.

NEW COMBINATIONS AND TAXONOMIES IN CLUSIACEAE

On preparing treatments of Clusiaceae for various floras in Central America, I have found the need to make several new combinations.

Dystovomita paniculata (J. D. Smith) Hammel, comb. nov. *Rheedia paniculata* J. D. Smith, Bot. Gaz. 55: 431. 1913. TYPE: Costa Rica. San José: between Río Union and Río Convento, 800 m, Feb. 1898, *Pittier 11957* (holotype, US).

Tovomita pittieri Engler, Bot. Jahrb. Syst. 58, Beibl. 130: 8. 1923. *Dystovomita pittieri* (Engler) D'Arcy, Ann. Missouri Bot. Gard. 65: 695. 1978. TYPE: Costa Rica. Cartago: Tuis Mountains, 1,000 m, May 1899, *Pittier 16094* (holotype, B, not seen; isotype, US).

Chrysochlamys clusiifolia subsp. *panamaensis* Maguire, Phytologia 36: 395. 1977. TYPE: Panama. Darién: Cerro Mali, 1,400 m, Jan. 1975, *Gentry & Mori 13769* (holotype, MO).

The following specimens probably represent most of the collections of this species.

Additional specimens examined. COLOMBIA. CHOCÓ: Río Truando, 40 200 m, *Duke 13320* (MO); Hoya del Río San Juan, 5 m, *Forero 4464* (MO); area of Baudó, 8 m, *Fuchs 21764* (MO); Serranía del Darién, 1,400 m, *Gentry 16775* (MO); Quibdó to Tutunendo, 90 m, *Gentry 24258a* (MO); 80 m, *Gentry 30286* (MO); Río Tagachi, 100 m, *Gentry 37059* (MO). This is the only species of *Dystovomita* in Central America. Its large, ovate to nearly round leaves with very distant parallel lateral veins and large ligulate swellings at the bases of the petioles make even sterile material unmistakable. The holotype at US consists of two sheets: US—1382472, a twig with the remains of an inflorescence, and US—1382473, leaves.

At MO we still have very little material of this genus from Venezuela, where a second species, *D. clusiifolia* (Maguire) D'Arcy, is endemic (one collection, *Schultes 14755*, is from Vaupés in southeastern Colombia). Although I can see no way to distinguish sterile material of *D. clusiifolia* from *D. paniculata*, seemingly minor differences in the staminate flowers, along the lines indicated by Maguire (1977) and D'Arcy (1978), do hold up for the many new collections of the latter species, which is restricted to Colombia, Panama, and Costa Rica. However, contrary to somewhat inaccurate and contradictory interpretations of prior authors, the flowers of both species have two bracteoles; the internode between the bracteoles and sepals is shorter in *D. clusiifolia* than in *D. paniculata*.

In addition to differences in the staminate flowers, the fruits of *D. clusiifolia* appear to have somewhat longer stigmas (or at least they persist longer) and are slightly larger at maturity than those of *D. paniculata*.

Garcinia intermedia (Pittier) Hammel, comb. nov. *Rheedia intermedia* Pittier, Contr. U.S. Natl. Herb. 13: 454. 1912. TYPE: Guatemala. Alta Verapaz: Río Lanquín, 300 m, Mar. 1902, *von Türckheim 8180* (holotype, US, photo MO; isotypes, F, MO).

Calophyllum edule Seemann, Bot. Voy. Herald 89. 1853. *Rheedia edulis* (Seemann) Planchon & Triana, Ann. Sci. Nat. Bot. Ser. 4. 14: 310. 1860. Not *Garcinia edulis* Exell, in Journ. Bot. 1927. TYPE (of *C. edule* Seemann): Panama. Veraguas: San Lorenzo, *Seemann s.n.* (BM, not seen, photo MO).

Rheedia tonduziana Engler, Bot. Jahrb. 58 Beibl. 130: 10. 1923. TYPE: Costa Rica. San José: along Río Virilla near San Juan, 1,100 m, May 1897, *Tonduz 11249* (holotype, B, not seen, photo MO; isotype, US, photo MO).

Robson (1958) discussed the logical error in maintaining *Rheedia* separate from *Garcinia*, essentially saying that no basis for separating them exists. Previously, *Garcinia* was not considered to occur naturally in the New World, only *Rheedia*. Features thought to distinguish *Rheedia* from *Garcinia* (number of perianth parts and degree of fusion of the stamens) are not constant in *Rheedia* and occur in both genera. Adams (1972) and Four-

net (1978) treated *Rheedia* as a synonym of *Garcinia* for floras within the West Indies. D'Arcy (1980) nevertheless kept the two genera separate on grounds that transferring the species of subg. *Rheediopsis* from *Garcinia* to *Rheedia* would be "more correct" than uniting *Rheedia* with *Garcinia*. Recent comparative work within the family supports Robson's position (P. Stevens, pers. comm.).

Seemann's epithet (*edule*) cannot be transferred to *Garcinia* as it would create a later homonym. *Rheedia intermedia* clearly belongs in *Garcinia* and provides the oldest available epithet for the species.

Garcinia intermedia is the only Central American member of the genus with a soft, edible, exocarp. All others have a thick, tough, inedible exocarp and delicious, white, acidic, sweet endocarp (as in the mangosteen, *Garcinia mangostana* L.). Leaf sizes and shapes are variable in the species and encompass the narrow-leaved material named as *Rheedia tonduziana*.

Garcinia macrophylla C. Martius, Flora 24. 2. Beibl. 35. 1841. *Rheedia macrophylla* (C. Martius) Planchon & Triana, Ann. Sci. Nat. Bot. Ser. 4. 14: 309. 1860. *Garcinia megaphylla* Verdc., Kew Bull. 31: 262. 1977, nom. illeg. (superfluous new name based on *Rheedia macrophylla* (C. Martius) Planchon & Triana). Not *Garcinia macrophyla* Miq. (1864). Not "*G. macrophylla* Anderson ex Hooker" (manuscript name listed in *Index Kewensis* (1895), this species published as *G. andersonii* Hooker, 1872). TYPE: Brazil. *Martius s.n.* (not seen).

Rheedia macrantha Standley & Steyermark, Field Mus. Nat. Hist. Bot. 23: 65. 1944. TYPE: Guatemala. Alta Verapaz: along Río Frío near Tactic, 1,400 m, Apr. 1941, *Standley 90524* (holotype, F).

In a footnote to a description of a new African species of *Garcinia*, Verdcourt (1977) transferred *Rheedia macrophylla* to *Garcinia* giving it the new but superfluous name, *G. megaphylla*. His citation states that *Rheedia macrophylla* Planchon & Triana is "non *Garcinia macrophylla* T. Anders., nec Mart., nec Miq." However, Planchon & Triana gave a complete citation of *G. macrophylla* C. Martius in synonymy of their *R. macrophylla*. Clearly, the basionym of *Rheedia macrophylla* (C. Martius) Planchon & Triana and oldest usage of the epithet "macrophylla" in *Garcinia* is *G. macrophylla* C. Martius. *Garcinia macrophylla* Miq., from Sumatra, published more than 20 years after Martius's Brazilian species, may need a new name. It is not certain that *G. macrophylla* C. Martius occurs in southern Central America (see discussion under *Garcinia magnifolia* Pittier).

Garcinia madruno (Kunth) Hammel, comb. nov. *Calophyllum madruno* Kunth, Nov. Gen. & Sp. 5: 202. 1822. *Rheedia madruno* (Kunth) Planchon & Triana, Ann. Sci. Nat. Bot. Ser. 4. 14: 315. 1860. TYPE: Colombia. Antioquia: Magdalena and Cauca valleys, 300–1,000 m, *Bonpland 1723* (P, not seen, photo MO).

Verticillaria acuminata Ruíz Lopez & Pavón, Syst. Fl. Peruv. 140. 1798. *Rheedia acuminata* (Ruíz Lopez & Pavón) Planchon & Triana, Ann. Sci. Nat. Bot. Ser. 4. 14: 314. 1860. Not *Garcinia acuminata* Planchon & Triana (1860). TYPE: Peru: *Ruíz & Pavón s.n.* (G, not seen, photo, MO).

Ruíz and Pavón's older epithet, *acuminata*, cannot be transferred to *Garcinia* as it would create a later homonym. *Calophyllum madruno* appears to provide the next-oldest available epithet for this distinctive species with tuberculate fruits.

Garcinia magnifolia (Pittier) Hammel, comb. nov. *Rheedia magnifolia* Pittier, Contr. U.S. Natl. Herb. 13: 454. 1912. TYPE: Costa Rica. Cartago: above Río Hondo near Matina, 400 m, Aug. 1901, *Pittier 16165* (holotype, US, photo MO).

Rheedia chocoensis Cuatrec., Ann. Inst. Biol. 20: 106. 1949. TYPE: Colombia. Valle: Río Calima, La Trojita, 5–50 m, Feb. 1944, *Cuatrecasas 16387* (holotype, F).

I consider Panamanian material previously identified as *Rheedia lateriflora* L. and *R. macrophylla* to be conspecific with *Garcinia magnifolia*. Stigmas of *G. humilis* (Vahl) C. Adams (= *R. lateriflora*) and *G. macrophylla* are lobed, and the mature fruits are apiculate, whereas *G. magnifolia* has globose mature fruits with a disc-shaped stigma. Recent Colombian collections demonstrate that *R. chocoensis* falls within the variability of *Garcinia magnifolia*.

Under the taxonomy adopted here, with fruiting material most important for identifying specimens, four native species of *Garcinia* occur in Central America. They can be distinguished by the following key:

KEY TO NATIVE SPECIES OF *GARCINIA* IN CENTRAL AMERICA

1a. Fruits with a soft, edible exocarp and 1 or 2 seeds; leaves usually drying dull on both surfaces ..... *G. intermedia*

1b. Fruits with a hard, inedible exocarp and often more than 2 seeds; leaves usually drying shiny above.
2a. Exocarp tuberculate; mature fruit mostly less than 4 cm in diam.; leaves drying metallic silver-green below, resin lines obvious on leaves ..... *G. madruno*
2b. Exocarp smooth; mature fruit often 6 cm or more in diam.; leaves drying green or brown below, resin lines inconspicuous.
3a. Leaves very coriaceous, drying greenish below; fruits globose, not apiculate ..... *G. magnifolia*
3b. Leaves ± membranaceous, drying brownish below; fruits ovoid, apiculate ..... *G. macrophylla*

A NEW SPECIES OF *CALYCOLPUS* (MYRTACEAE) FROM THE VENEZUELAN GUAYANA

In preparation of a treatment of the subtribe Myrtinae (Myrtaceae) for the *Flora of the Venezuelan Guayana* a new species of *Calycolpus* has come to my attention. It is known to me through two collections, both from Estado Bolívar, Venezuela. It clearly belongs to *Calycolpus* as shown by the following combination of characters: flowers pentamerous and erect; stamens exserted, the anthers elongate, with several glands in the connective; seed coat lustrous with no pulpy covering, the outer seed coat ca. 1 cell thick at narrowest point, the superficial cells of the seed coat nearly isodiametric.

Calycolpus bolivarensis Landrum, sp. nov. TYPE: Venezuela. Bolívar: entre kms 146 y 145 de carretera a San Juan de Manapiare, 150 m, 5 Mar. 1977 (fl), *A. Fernández 3068* (holotype, MY). Figure 1.

C. cochleato McVaugh primo adspectu simillima, sed folio sessili vel subsessili, oblongo-lanceolato; petioli 0–1 mm longi; nervi laterali prominenti subtus; pedunculis in brachyblastos bracheatos aggregatos in extremitatibus ramunculorum.

Frutex circa 1-metralis; pili albi, simplices; ramuli juventute dense puberulentes; folia 4.5–10 cm longa, 1.8–3.3 cm lata, 2–3-plo longiora quam latiora; apex acuminatus; basis subcordata; laminae coriaceae, in sicco pallido-brunneae vel atrorufo-brunneae; hypanthium campanulatum, circa 4 mm longum, dense puberulum; stamina circa 185, circa 8 mm longa, antheris circa 0.8 mm longa, connectivum circa 10-glandulis; ovarium 3-loculare, loculis 15–19-ovulatis; stylus 7–10 mm longus, glaber.

Shrub ca. 1 m high, the twigs, leaves, and flowers sparsely to densely puberulent on most surfaces; hairs whitish, simple, mainly appressed, <0.1–ca. 0.8 mm long; young twigs grayish to reddish brown, densely puberulent. Leaves sessile or subsessile; blades stiffly coriaceous, drying light brown to dark reddish brown, oblong-lanceolate, 4.5–10 cm long, 1.8–3.3 cm wide, 2–3 times as long as wide, moderately to sparsely puberulent or densely puberulent along the midvein, the margin revolute, the apex acuminate, the base subcordate; midvein impressed to nearly flat above, prominent below; lateral veins ca. 20–22 pairs, nearly straight, leaving the midvein at nearly a 90° angle, visible or not visible above, prominent below; marginal veins about equaling laterals in prominence, running about parallel to and ca. 2–3 mm from the margin; petiole 0–1 mm long, 1–3 mm wide. Peduncles ca. 1–2 cm long, ca. 1.5 mm wide at apex, velvety puberulent, borne in the axils of bracts, clustered in bracteate shoots at the tips of branches; bracteoles clasping the hypanthium, triangular, ca. 0.6–1.5 mm wide, 1–2 mm long. Calyx lobes before anthesis about triangular, ca. 2–3 mm long, 2–2.5 mm wide, densely to sparsely appressed puberulent within, sparsely puberulent without, the hypanthium tearing 1–3 mm between the lobes at anthesis, the calyx lobes thus longer than before; petals sparsely to moderately puberulent; hypanthium campanulate, ca. 4 mm long, densely velvety puberulent; disk ca. 5 mm across, densely puberulent on staminal ring; stamens ca. 185, ca. 8 mm long; anthers ca. 0.8 mm long, with ca. 10 glands in connective; ovary 3-locular; ovules 15–19 per locule, ± multiseriate; style 7–10 mm long, glabrous. Fruit globose, probably ca. 1 cm diam.; seeds ca. 12 per fruit, ca. 4 mm long, the seed coat lustrous, ca. 1 cell thick across distal wall, the cells nearly isodiametric.

Additional specimen examined. Venezuela. Bolívar: entre Guaniamo y Perro de Agua, ca. 100–280 m, 9 June 1984 (young fr), *S. Lopez-Palacios, A. Carabot & C. Rosquete 4521* (NY).

Calycolpus bolivarensis is most similar to *C. cochleatus*. The differences are summarized in the key below.

1a. Leaves oblong-lanceolate, sessile to subsessile, the petiole 0–1 mm long; lateral veins prominent below; peduncles borne in the axils of bracts, clustered in bracteate shoots at the tips of young branches; hypanthium densely puberulent ..... *C. bolivarensis*

1b. Leaves elliptic to obovate, petiolate, the petiole 1–6 mm long; lateral veins indistinct to scarcely visible below; peduncles borne in the axils of leaves or bracts, solitary or clustered in axillary bracteate shoots along the length of young branches; hypanthium densely lanate ..... *C. cochleatus*

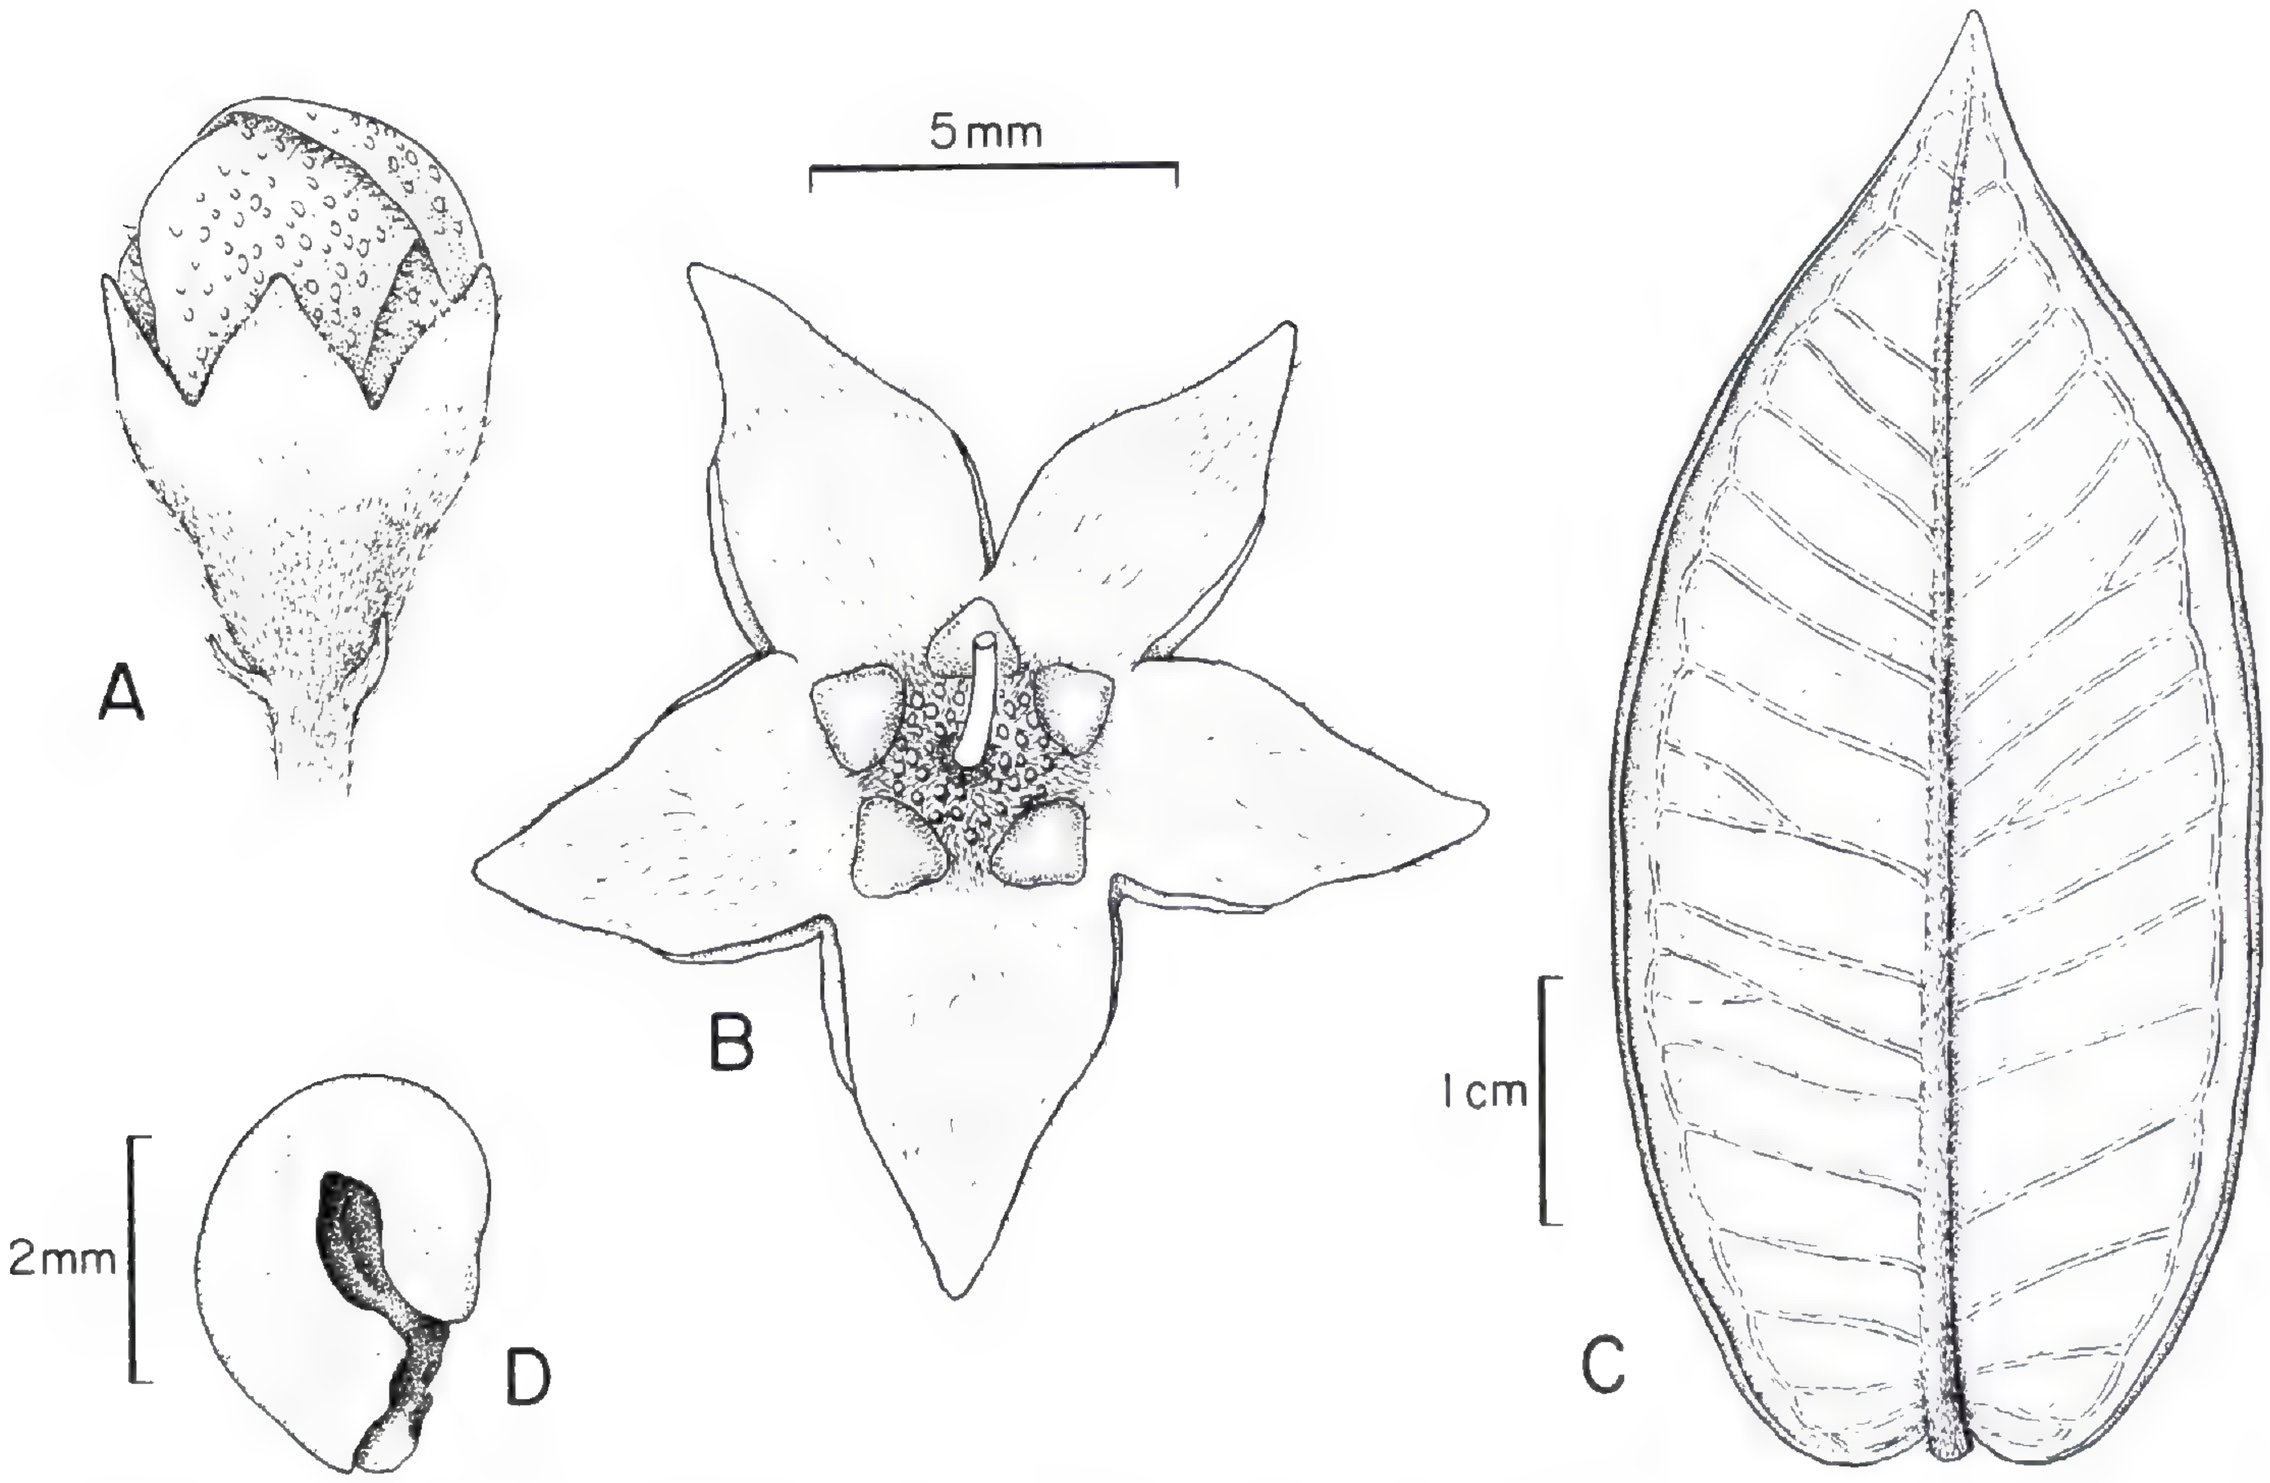

FIGURE 1. *Calycolpus bolivarensis*. A. Flower bud. B. Flower after anthesis, showing subtriangular petal scars, stamen scars, and tears between calyx lobes.—C. Leaf from below.—D. Lateral view of seed. A, C from *Fernandez 3068* (MY); B, D from *Lopez-Palacios et al. 4521* (NY). Drawn by Bobbi Angell.

I am grateful to Bruce Holst for discovering and sending me the specimen of *Calycolpus bolivarensis* from MY that I have used as the type.

CHROMOSOME NUMBER IN *PHENAKOSPERMUM* AND *STRELITZIA* AND THE BASIC CHROMOSOME NUMBER IN STRELITZIACEAE (ZINGIBERALES)

Chromosome counts are available for most Afro-Madagascan members of Strelitziaceae but until now the neotropical *Phenakospermum* has been unknown cytologically. Chromosome cytology of the small southern African genus *Strelitzia* is comparatively well known. The two acaulescent species *S. reginae* Ait. (syn. *S. parvifolia* Ait.) and *S. juncea* Link (possibly only a form of *S. reginae*) have diploid numbers of $2n = 14$; in contrast, the caulescent *S. alba* (L.f.) Skeels (syn. *S. augusta* Thunb.) has $2n = 22$ (Table 1). The closely related *S. nicolai* Regel & Koern., also caulescent, has been reported by Satô (1948, 1960) as having $2n = 14$. The remaining species, *S. caudata* R. A. Dyer, is unknown cytologically.

It has seemed puzzling that the chromosome number of *S. nicolai* corresponded with the two acaulescent species rather than with the allied caulescent *S. alba*, particularly as the merit of maintaining the two species as separate (Geldenhuys, pers. comm.) is in some doubt. We have now established that at least one Transkeian population of *S. nicolai* has the same chromosome number, $2n = 22$, as *S. alba*. The chromosome number in *Phenakospermum* is also $2n = 22$.

Materials and Methods

Seeds collected in the wild were germinated in the greenhouse. Actively growing root tips were harvested at mid morning into saturated aqueous mono-bromo-naphthalene and left at room temperature for four hours before fixation in 3:1 absolute ethanol-glacial acetic acid for two minutes. After hydrolysis in 10% HCl for six minutes at 60°C, the apical portions of the tips were squashed in FLP orcein (Jackson, 1972). Voucher data are as follows: *Phenakospermum guianensis* Aublet, Guyana: *DeFilipps s.n.* (US); *Strelitzia nicolai* (L.f.) Skeels, South Africa. Transkei: coastal bush at Mkambati Nature Reserve, *P. Goldblatt 7603a* (MO).

Observations and Discussion

The diploid chromosome number of *P. guianensis* and *S. nicolai* is $2n = 22$. The chromo-

[1] Reports by Satô (1948, 1960) of $n = 7$ in this species are presumed to be incorrect and hence are excluded from the table.

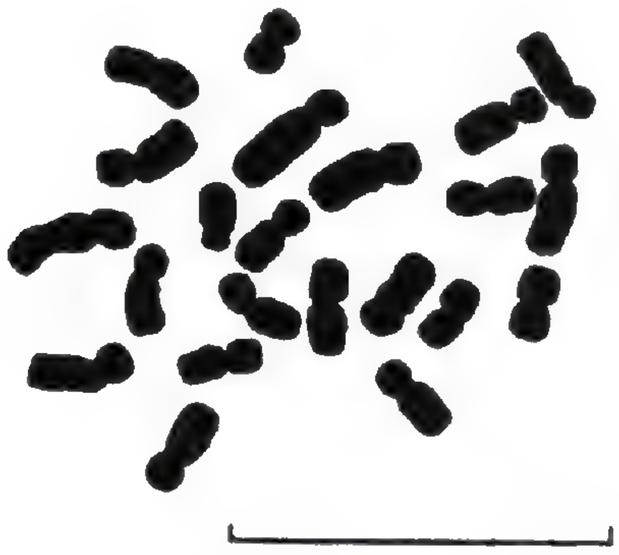

FIGURE 1. Mitotic metaphase in *Strelitzia nicolai*. Scale bar = 10 μm.

somes are of moderate size, ranging 1.5–3.5 μm in the method used. The chromosomes are mostly acrocentric, but four of the smaller pairs are submetacentric (Fig. 1). The karyotypes are comparable to those illustrated by Small et al. (1980) for *S. reginae* and *S. juncea* except for the difference in the number of chromosomes.

It is likely that Satô's count of $2n = 14$ for *Strelitzia nicolai* is incorrect. Our count provides additional evidence that the caulescent species of *Strelitzia* have $x = 11$. This corresponds with the number in the Madagascan *Ravenala*, also $x = 11$ (Table 1), the least specialized member of the family according to Lane (1955). All the arborescent members of Strelitziaceae thus have $x = 11$.

The families most closely related to Strelitziaceae—Musaceae and Heliconiaceae—have $x = 11$ and 12 respectively (Goldblatt, 1980). This makes it reasonable to hypothesize that $x = 11$ is basic for Strelitziaceae, as Mahanty (1970) suggested. If this is correct, it follows that the arborescent members of the family have retained the ancestral base number while the acaulescent species of *Strelitzia* have a derived chromosome number. This implies that the acaulescent condition in the family is secondary, which is consistent with the conclusions of Lane (1955) and Tomlinson (1960).

The alternative, that $x = 7$ is basic, seems to us less likely, although Chakravorti (1960) has suggested that $x = 11$ in Musaceae (including Strelitziaceae and Heliconiaceae) is derived from $x = 7$ by fragmentation across eight secondary constrictions in the *S. reginae* karyotype. This process is mechanically unlikely (Jones, 1977). In light of the predominance of decreasing over ascending aneuploidy in plants (Stebbins, 1950; Jones, 1977 & pers. comm.; Goldblatt, 1981), we assume that the chromosome number in the acaulescent species of *Strelitzia* was achieved by chromosome fusion leading to the reduced base number. Critical measurement of the quantity of DNA in *Strelitzia* may help solve this question.

Support for this study by grants DEB 81-19292 and BSR 85-00148 from the U.S. National Science Foundation is gratefully acknowledged.

ENCEPHALARTOS VOIENSIS (ZAMIACEAE), A NEW EAST CENTRAL AFRICAN SPECIES IN THE *E. HILDEBRANDTII* COMPLEX

In the past 30 years, several locally endemic species of *Encephalartos* have been described for Central Africa. Most are from Mozambique (Dyer & Verdoorn, 1969; Lavranos & Goode, 1985), Zimbabwe (Dyer & Verdoorn, 1969), and, to a lesser extent, Zaire (Devred, 1959; Malaisse, 1969). All of these taxa are located west and southwest of a line connecting Lake Victoria, Lake Tanganyika, and Lake Niassa (Fig. 1). Little work has taken place on *Encephalartos* east of this line. In fact, the distribution map in the most thorough and recent work on African *Encephalartos* (Melville, 1957) shows no collections between the line and the east coast of Africa other than two locally endemic species he described: *E. bubalinus* Melville and *E. tegulaneus* Melville. Heenan (1977) repeated Melville's (1957) descriptions and included a discussion of three undescribed and imperfectly known, presumably new taxa from this area.

One of us (JPS) has recently collected material of *Encephalartos* in the central border region of Kenya and Tanzania. In these collections there is

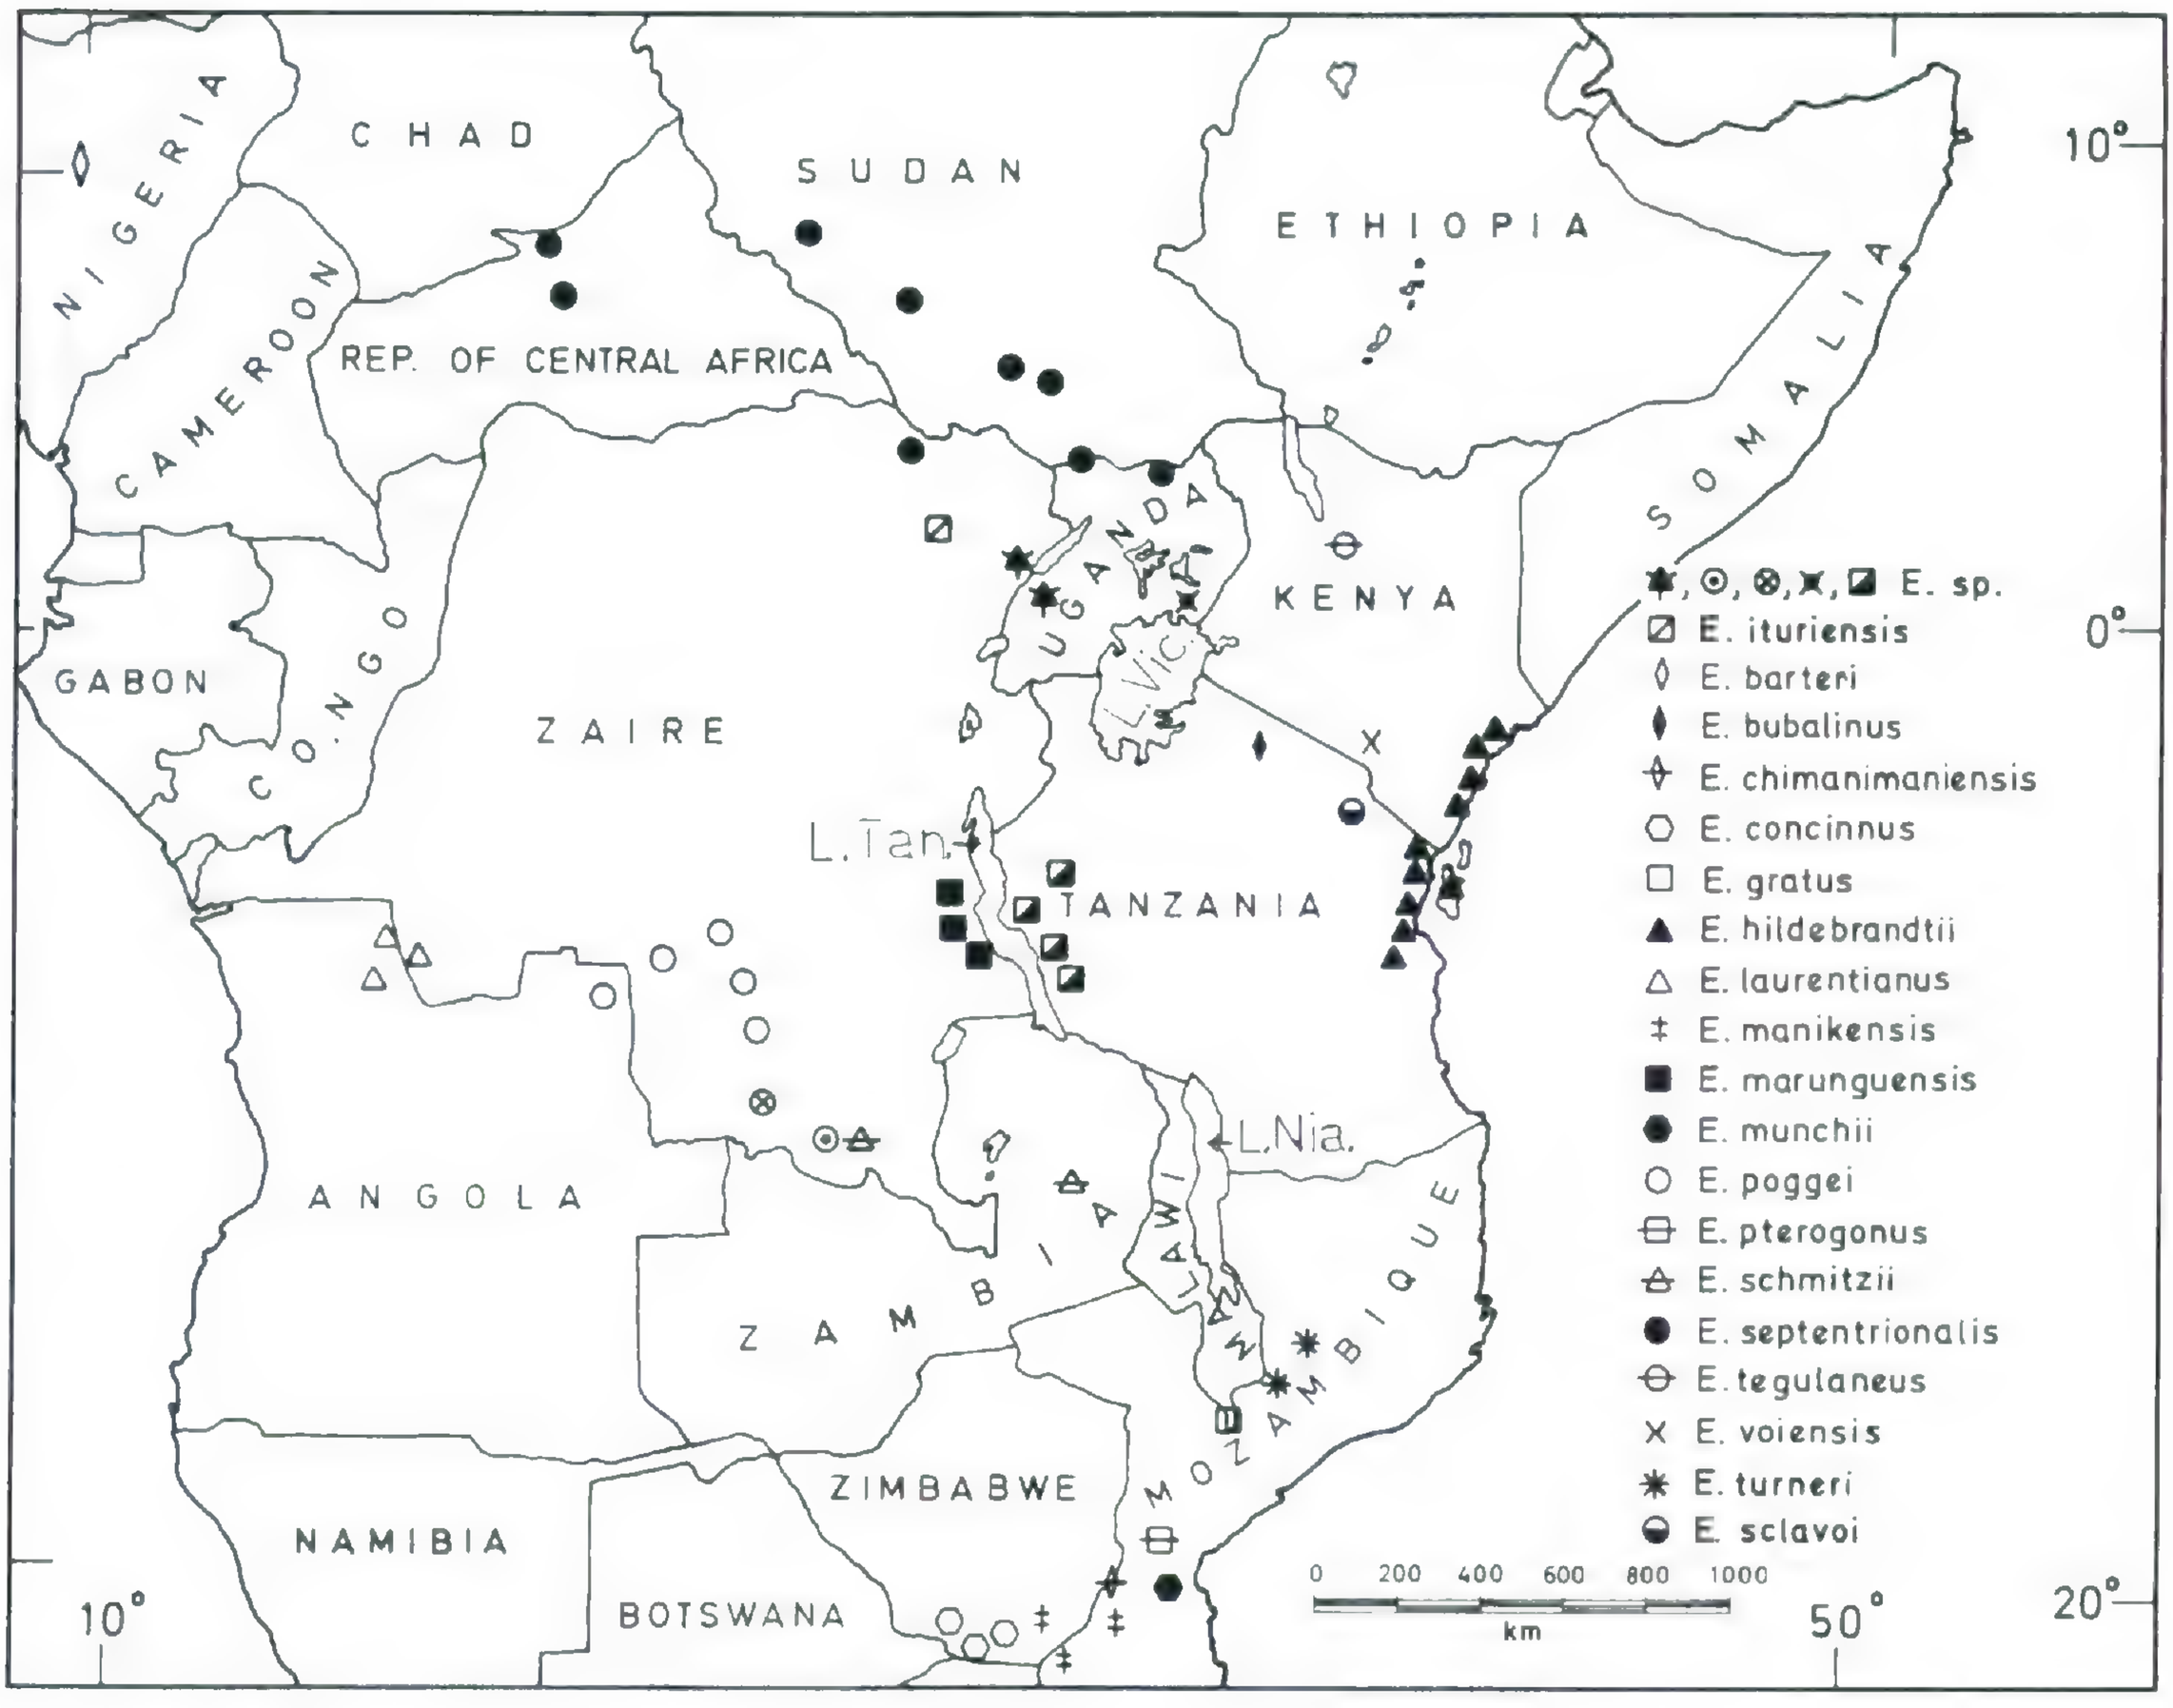

FIGURE 1. Distribution map of *Encephalartos* species in Central Africa. Derived, in part, from Melville (1957) and Devred (1959). L. Nia. = Lake Niassa, L. Vic. = Lake Victoria, L. Tan. = Lake Tanganyika.

at least one new species, which is known to us from two localities near Voi, Kenya. This species appears in many respects, including locality, to correspond to Heenan's (1977) *Encephalartos* "sp. B." This species is described below and is followed by a discussion of its relationships and affinities to neighboring congeners.

Encephalartos voiensis Moretti, D. Stevenson & Sclavo, sp. nov. TYPE: Kenya: Voi, 2 Jan. 1986 (♀), *Sclavo 1* (holotype, K). Figure 2.

Truncus erectus, ad 2.5 m altus, 35–70 cm diam. Cataphylla acuminato-lanceolata vel linearia, dense tomentosa. Folia 2–4 m longa, oblonga, ad basin abrupte attenuata; rachis glabra duobus sulcis superne praedita. Foliola mediana alternata vel subopposita, oblanceolata, subfalcata, sensim acuminata, pungentia, marginibus calloso-dentatis, dentibus 1–5, basi abrupte cuneata superne 1–5 infereque 0–1 spinosa, 25–40 cm longa, 4 cm lata; foliola inferiora abrupte diminuta, bifurcata; foliola infima in spinas mutata. Strobilus ♂ lineare-cylindricus, 45–50 cm longus, 10 cm diam.; pedunculus ebracteatus, 5–7 cm longus, 3–5 cm diam.; microsporophylla ad axin perpendicularia, deltoideo-cuneata, 35–40 mm longa, 22–25 mm lata, bulla deflexa praedita. Strobilus ♀ cylindricus vel ovoideo-cylindricus, 50–60 cm longus, 15–20 cm diam.; pedunculus ebracteatus, 5–7 cm longus, 3–5 cm diam.; megasporophylla mediana rhomboidea, 35 mm longa, 40 mm lata; pedicellus 10 mm longus, tribus abaxialibus faciebus praeditus; bulla rhomboidea, 40 mm lata, 18 mm alta, 24 mm profunda; bullae terminalis facies hexagona atque vulticulo praedita; adaxialis facies ex tribus trapezoideis partibus constituta atque tuberculata crista tuberculatoque margine praedita; lateralis bullae lobi 7–9 mm longi, 2–4 mm lati, ad latera complanati.

Trunk erect, to 2.5 m tall, 35–70 cm diam., straight to slightly tapering towards apex, leaf bases persistent. *Leaves* 2–4 m long, oblong, gradually tapered basally and becoming abruptly spinose in the lower ⅕. *Petiole* bulbous and tomentose. *Rachis* glabrous and with 2 shallow longitudinal adaxial grooves between leaflet insertions. *Median leaflets* alternate to subopposite, coriaceous, adaxially concave, blue-green, inserted at a right angle to the rachis and slightly oblique in the ab-adaxial plane, oblanceolate, subfalcate, 25–40 cm long, 4 cm wide, gradually acuminate apically and pungent, abruptly attenuate and strongly inequilateral basally, superior margin with 1–5 strong spinose teeth on the basal curve and with 1–5 barely discernible callose teeth along the rest, inferior margin with 0–1 small teeth basally and 1–5 barely discernible callose teeth along with the rest. *Lower leaflets* exhibiting an abrupt transition from those with 1 basal spinose tooth on the superior margin to those with bifurcate apices to completely reduced and pungent lower leaflets. *Microsporangiate strobilus* long-cylindric, greenish yellow when young, yellow to tan when shedding pollen, 45–50 cm long, 10 cm diam.; peduncle without bracts, glabrous, 5–7 cm long, 3–5 cm diam. *Median microsporophylls*, 35–40 mm long, 22–25 mm wide, perpendicular to the strobilus axis, cuneate to deltoid, bulla deflexed, terminal facet triangular to pentagonal. *Megasporangiate strobilus* cylindrical to ovoid-cylindrical, green to yellow when young, yellow to tan when mature, 50–60 cm long, 15–20 cm diam.; peduncle ebracteate and glabrous, 5–7 cm long, 3–5 cm diam. *Median megasporohylls* pedicellate with rhomboid bulla, 35 mm long, 40 mm wide; pedicel with 3 abaxial facets, the median facet inconspicuous and triangular, 10 mm long. *Bulla of megasporophyll* rhomboidal, 40 mm wide, 18 mm high, 24 mm deep; the terminal facet slightly concave and hexagonal, 15–17 mm wide, 6–8 mm tall; adaxial face with 2 lateral trapezoidal facets, a median rectangular to trapezoidal facet, and a short median lobe 2–4 mm wide and long, the margin and seminal fringe tuberculate; abaxial face with 2 lateral trapezoidal facets and a median rectangular to trapezoidal facet with obtuse lateral sagittal ridges, the inferior ridge and sagittal crest tuberculate; lateral lobes 7–9 mm long, 2–4 mm wide, flattened laterally.

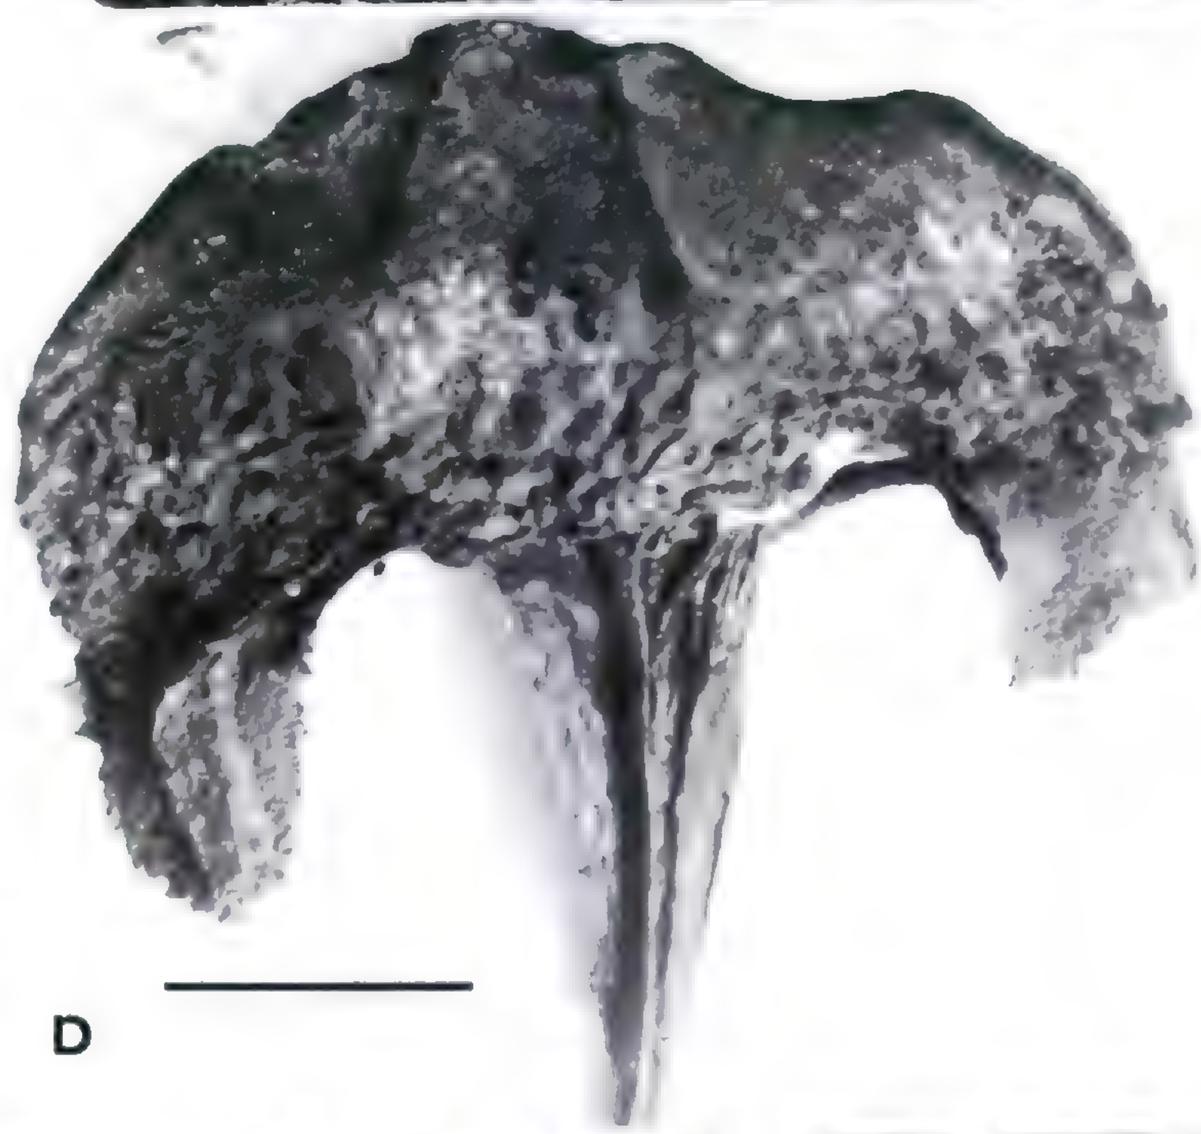
Additional specimens examined. KENYA: near Voi, Mlilonyi Hill, 4 Jan. 1986 (♂), *Sclavo 2* (EA, K, MO, NAP).

Encephalartos voiensis lives in isolated mountains surrounded by dry savanna in which species of *Encephalartos* do not occur. The new species occurs on steep rocky slopes in cloud forest at 1,500–1,800 m elevation as an understory plant. It also grows in partial shade and full sun areas of forest clearings.

Encephalartos voiensis shares some characters with *E. bubalinus*, *E. gratus* Prain, *E. hildebrandtii* A. Br. & Bouché, and *E. tegulaneus*, which are all found in the same general vicinity (Fig. 1); and, to a lesser extent, it resembles *E. manikensis* (Gilliland) Gilliland and its allies in Central Mozambique and in Zimbabwe. *Encephalartos voiensis* shares different features with each of these taxa. For example, foliage characteristics are closest to *E. bubalinus* and (especially) *E. hildebrandtii* in that 1–5 spinose teeth are present on the basal curve of the superior margin of the median pinnae, and at least one spinose tooth is present near the basal portion of the inferior margin. *Encephalartos voiensis* differs from these two species by having subfalcate, very abruptly cuneate basally, very dark green to blue-green leaflets, and the transition to

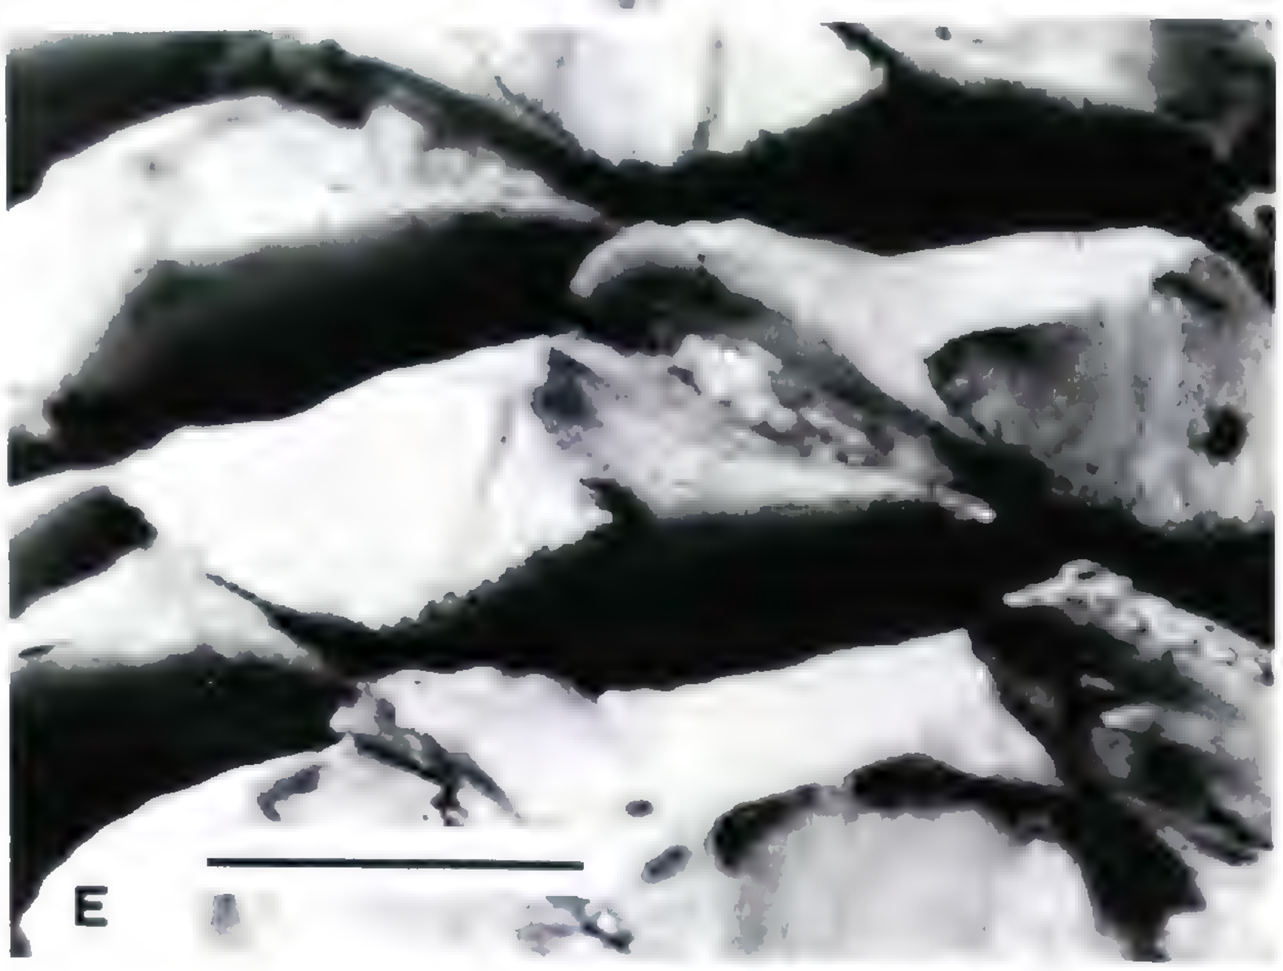
A

C



D

B



E

reduced leaflets in the lower ⅕ of the rachis is abrupt rather than gradual. *Encephalartos voiensis* can be distinguished further from *E. bubalinus* because the former has median leaflets 4 (vs. 1–2) cm wide, 25–40 (vs. 10–20) cm long, and gradually acuminate (vs. acute) apices. In general, in *E. hildebrandtii*, the median leaflet apices are either bifurcate or trifurcate; in *E. voiensis*, by contrast, they are always pungent. Moreover, the median leaflets of *E. hildebrandtii* have up to nine spinose teeth along each margin; in *E. voiensis* these teeth are reduced to barely discernible callose bumps.

The mega- and microsporangiate strobili of *E. voiensis* resemble those of *E. bubalinus*, *E. gratus*, *E. hildebrandtii*, and *E. tegulaneus* with respect to overall size, shape, and color. There are, however, significant differences in mega- and microsporophyll characters. As in vegetative characters, *E. voiensis* shares individual characters with each of the aforementioned species, but none that is common to all except perhaps the presence of inferior and sagittal crest tubercles. For example, only *E. gratus* and *E. voiensis* have a rectangular to trapezoidal adaxial median lobe. This median lobe is 5–12 mm long in *E. gratus* but only 2–4 mm long in *E. voiensis*. *Encephalartos tegulaneus* has a unique abaxial tuberculate facet that replaces the abaxial angle of the pedicel of its megasporophylls. This feature also occurs in *E. voiensis*, but here the facet is narrower, usually does not extend the full length of the pedicel, is barely discernible in herbarium material, and is nontuberculate. The ab- and adaxial margins of the bulla of the megasporophylls of *E. voiensis* and *E. hildebrandtii* are tuberculate and without ridges, whereas those of *E. bubalinus*, *E. gratus*, and *E. tegulaneus* always have some distinct ridges. The overall appearance of the megasporophylls of *E. voiensis* in shape and arrangement of the bulla facets is most similar to those of *E. hildebrandtii*. Compared with the previously discussed taxa, the lateral lobes of the bulla of *E. voiensis* are uniquely smaller and thinner and appear laterally compressed in the ab-adaxial plane.

The deltoid to cuneate microsporophylls of *E. voiensis* are more similar to those of *E. bubalinus* than to the oblong microsporophylls of *E. gratus*, *E. hildebrandtii*, and *E. tegulaneus*. In addition, only *E. voiensis* and *E. bubalinus* have their microsporophylls inserted at a right angle to the strobilus axis at pollen shedding, whereas in the other species they are either ascendant as in *E. gratus* and *E. hildebrandtii* or descendant as in *E. tegulaneus*. *Encephalartos voiensis* has a median facet on the ab- and adaxial bulla faces; these median facets are not present in *E. gratus*.

Encephalartos voiensis exhibits little variability except that some leaflet characters appear to be associated with habitat differences. The leaflets of plants growing in deep shade are thinner in texture and barely subfalcate, and they generally have fewer and smaller marginal spinose teeth. Only shade plants exhibit these features, and they would most likely change under exposure to higher light intensities, as Stevenson et al. (1986) observed in *Ceratozamia latifolia* under otherwise similar conditions.

Even though the relationship of *E. voiensis* is not completely clear, it is our opinion, based on vegetative morphology, that *E. voiensis* is most closely related to *E. hildebrandtii*. This is because in the cycads, in general, vegetative characters are more useful in separating species as, for example, in *Ceratozamia* (Stevenson et al., 1986), *Dioon* (Sabato & De Luca, 1985), and *Macrozamia* (Johnson, 1959). There are several reasons for this. First, vegetative characters are always present and often exhibit more obvious macroscopic diversity than do reproductive characters. Secondly, most data concerning reproductive characters are either fragmentary or nonexistent, and herbarium material is highly unreliable because of the vast amount of distortion of size and shape induced by drying. Thirdly, because all cycads are dioecious, we think it is important to establish vegetative characters that can be correlated with reproductive characters to establish a common denominator. In the case of the species discussed in this work, microsporophyll and megasporophyll characters do help corroborate the species delimitations indicated by vegetative characters. Finally, cycads often exhibit extreme changes in vegetative morphology between species of different habitats and or localities while at the same time exhibiting only subtle differences in reproductive morphology. These vegetative changes

are stable and remain so even when the species are brought together and cultivated through successive generations in a uniform environment.

The high incidence of locally endemic species of *Encephalartos* in Central Africa appears to be related to habitat preference and physical geography in this region. That is, in general, *Encephalartos* here prefers steep wooded slopes, and this habitat occurs in isolated areas surrounded by savanna in which this genus does not occur. Even *E. hildebrandtii* (Fig. 1) occurs at the top and on the sides near the top of coastal cliffs and on the sides of river valleys. With the appropriate habitats isolated from each other, there is the opportunity for locally endemic taxa to differentiate. *Encephalartos voiensis* fits this pattern because it also occurs on steep slopes of isolated mountains surrounded by savanna. As more areas of Central Africa are explored for *Encephalartos* populations, more new taxa will certainly be discovered.

Keys to East Central African Species of *Encephalartos*

KEY TO VEGETATIVE PLANTS

1a. Median leaflet apices bi- or trifurcate ..... *E. hildebrandtii*
1b. Median leaflet apices sharply pointed, ending in a spikelike tip.
  2a. Median leaflets subfalcate ..... *E. voiensis*
  2b. Median leaflets linear to oblanceolate.
    3a. Median leaflets linear, narrower than 2 cm ..... *E. bubalinus*
    3b. Median leaflets lanceolate or oblanceolate, wider than 2 cm.
      4a. Median leaflets oblanceolate, margins reflexed, distinctly striate below ..... *E. tegulaneus*
      4b. Median leaflets lanceolate, margins flat, indistinctly striate below ..... *E. gratus*

KEY TO MEGASPORANGIATE PLANTS

1a. Microsporophylls oblong, either ascendant or descendant at pollen shedding.
  2a. Bulla puberulent ..... *E. gratus*
  2b. Bulla glabrous.
    3a. Microsporophylls ascendant ..... *E. hildebrandtii*
    3b. Microsporophylls descendant ..... *E. tegulaneus*
1b. Microsporophylls deltoid to cuneate, at right angles to strobilus axis at pollen shedding.
  4a. Lateral ridges of bulla acute ..... *E. bubalinus*
  4b. Lateral ridges of bulla subacute to obtuse ..... *E. voiensis*

KEY TO MEGASPORANGIATE PLANTS

1a. Median lobe of bulla well developed, 7–12 mm long, bulla puberulent ..... *E. gratus*
1b. Median lobe of bulla absent or if present shorter than 5 mm, bulla glabrous or nearly so.
  2a. Median lobe of bulla 2–4 mm long ..... *E. voiensis*
  2b. Median lobe of bulla absent.
    3a. Bulla subtriangular, abaxial angle of pedicel absent ..... *E. tegulaneus*
    3b. Bulla rhomboid, abaxial angle of pedicel present.
      4a. Adaxial margin of bulla with radiating ridges ..... *E. bubalinus*
      4b. Adaxial margin of bulla with tubercles ..... *E. hildebrandtii*

A NEW SPECIES OF *PERSEA* (LAURACEAE) FROM SURINAM, WITH A DISCUSSION OF ITS POSITION WITHIN THE GENUS

In a shipment of Lauraceae recently received from the University of Surinam, Paramaribo, I encountered a specimen of *Persea* that turned out to represent a new species, differing from all other neotropical *Persea* species by its deciduous and strongly unequal tepals.

Persea julianae van der Werff, sp. nov. TYPE: Surinam: Wilhelmina Mountains, Juliana Peak, small tree, 7 m tall, flowers very pale yellow, axes of inflorescence reddish, *Schulz 10234* (holotype, MO; isotype, BBS). Figure 1.

A congeneribus tepalis deciduis et valde inaequalibus differt.

Tree, 7 m tall. Very young shoots and buds densely appressed-pubescent, the twigs soon becoming glabrous. Leaves alternate, elliptic, 10–14 × 3.5–5 cm, ± coriaceous, the base acute, the tips acute or shortly acuminate, the upper surface glabrous, the lower surface with scattered appressed hairs, the midvein clearly impressed and the lateral veins weakly impressed on upper surface, both of these vein types clearly raised on lower surface; tertiary venation weakly raised on lower surface. Petioles 1–1.5 cm long, glabrous, canaliculate. Inflorescences 4–6 cm long, in axils of deciduous bracts or leaves, paniculate, appressed-pubescent, the axes reddish (fide collector). Pedicels ca. 4 mm long. Flowers very pale yellow. Tepals 6, strongly unequal, united at the very base and falling off in old flowers as a unit, with stamens and staminodia attached. Outer tepals broadly ovate, ca. 2 mm long, appressed-pubescent outside, glabrous inside. Inner tepals elliptic, ca. 6 mm long, appressed-pubescent on both surfaces. Fertile stamens 6, these representing the outer 2 whorls, ca. 5 mm long, the filament slender, ca. 4 mm long, densely pubescent, the anther glabrous, 4-celled, the cells introrse. Stamens of the third whorl about as long as the outer stamens, the filament similarly pubescent, the anther as wide as the filament and devoid of anther cells; glands present, sub-basal. Outer 9 stamens with widened bases. Staminodia (whorl IV) ca. 2.5 mm long, widened at base, filament densely pubescent, inside of the anther glabrous except for an apical tuft of hairs, the outside sericeous, the base cordate. Ovary ellipsoid, ca. 1 mm long, glabrous or with few hairs near the apex; style ca. 2.5 mm long, glabrous. Fruit unknown; tepals deciduous in very early fruiting stage.

The distinctive characters of *P. julianae* make it difficult to place in the most recent infrageneric classification. In her revision of the neotropical species of *Persea*, Kopp (1966) recognized two subgenera. Subgenus *Persea* is characterized by its equal tepals that are pubescent on inner and outer surfaces, usually puberulous ovary, and tepals deciduous at the fruiting stage. This subgenus includes the type species of *Persea*, *P. americana* Mill., and three other Central American species. Subgenus *Eriodaphne* is characterized by its strongly unequal tepals with the outer tepals internally glabrous, usually glabrous ovary, and persistent tepals in the fruiting stage. This subgenus includes about 70 neotropical species and is further divided by Kopp (1966) into four sections. Section *Mutisaea* includes the species with a corymbiform inflorescence; section *Hexanthera* includes species with only six fertile stamens (representing the outermost whorls), section *Aurataea* includes species with a (sometimes slightly) pubescent ovary; and section *Eriodaphne* includes the remaining species, with a glabrous ovary. The species with partly or entirely two-celled stamens belong to section *Eriodaphne*. Thus, the two subgenera can be readily identified in flower (tepals equal vs. unequal) and fruit (tepals deciduous vs. persistent).

The usefulness of this classification of the neotropical *Persea* species is undercut by several species with characters of both subgenera. Several Central American species (for example *P. albida* Kostermans, *P. rigens* Allen, and *P. sylvatica* van der Werff) have equal tepals, which are persistent in the fruiting stage. These species were included in section *Eriodaphne* by Kopp, but the equal tepals

FIGURE 1. *Persea julianae*.—A. Habit.—B. Flower.—C. Detail of flowers showing two outer tepals (small), each with a fertile stamen (whorl I) and a tall staminode (whorl III), and one inner tepal (long) with a fertile stamen (whorl II) and a short, sagittate staminode (whorl IV).—D. Staminode of whorl III, with sub-basal glands.—E. Stamen of whorl I/II.—F. Pistil.—G. Staminode of whorl IV.—H. Old flower, showing dehiscence of tepals and stamens.

do not support this placement. Kopp's (1966) infrageneric classification is weakened further by the unequal tepals deciduous in the fruiting stage of *P. julianae*.

If it were not for the deciduous tepals, *P. julianae* would be immediately placed in subg. *Eriodaphne* section *Hexanthera*, which is represented in Amazonian Brazil and Venezuela by *P. fastigiata* Kopp, *P. pseudofasciculata* Kopp, and *P. hexanthera* Kopp. These species are compared in Table 1.

Persea julianae, named after the Queen Mother of the Netherlands, is only known from the type collection from the Juliana Peak in Surinam at an elevation of 1,050 m. It was collected in a 20-m-tall forest, rooting in a thick humus layer on sandy clay.

Kostermans (1936) recorded three species of

TABLE 1. Selected characters of *Persea julianae*, *P. pseudofasciculata*, *P. fastigiata*, and *P. hexanthera*, based on MO type specimens, with exception of *P. hexanthera*, where data are based on the protologue and the collection *Bernardi s.n.*, annotated by Kopp.

	Tepals	Length of Inflorescence	Pubescence	Lengths of Inner Tepals	Lengths of Pedicels	Twigs	Lengths of Petioles
P. julianae	deciduous	⅓–½ leaves	sparse, appressed	6 mm	4 mm	solid	1.0–1.5 cm
P. pseudofasciculata	persistent	+ ½ leaves	dense, appressed	7 mm	3 mm	hollow	2.5 cm
P. fastigiata	persistent	longer than leaves	sparse, appressed	4 mm	3 mm	solid	1.0–1.5 cm
P. hexanthera	persistent	longer than leaves	sparse, appressed	8.5 mm	5 mm	hollow	2.5 cm

Persea from Surinam, *P. americana* Miller, P. *benthamiana* Meissner, and *P. coriacea* Kostermans. As noted, the strongly unequal tepals, glabrous ovary, and number of fertile stamens separate *P. julianae* from the cultivated *P. americana*. Specimens treated by Kostermans (1936) as *P. benthamiana* were included by Kopp (1966) under *P. nivea* Mez and are characterized by having nine fertile stamens, persistent tepals, and glaucous whitish lower leaf surfaces.

Persea coriacea is an enigmatic species known only from the type collection, from the Hendrik Peak in the Emma Chain, not far from the Juliana Peak. This species is described as having subequal tepals ± 1.75 mm long and nine fertile stamens; these details separate it clearly from *P. julianae*. Kostermans (1936) also mentioned that the fruit was subtended by a small, flat cupule with an entire margin, a character not found in any other *Persea* species. This was probably one reason why Kopp (1966) excluded *P. coriacea* from *Persea* without suggesting an alternative generic placement. The MO isotype of *P. coriacea* does not solve these difficulties. The label states that flower buds and fruits were collected. Presence of floral buds and fruits on the same specimen is very unusual for Lauraceae and is often the result of a disease in which galls, developed from buds, are mistaken for fruits. The buds on the MO isotype *are* diseased, which explains Kostermans's observation that frequently a staminode of the fifth whorl is present. The papillose lower leaf surface is against its inclusion in *Persea*. Papillose lower leaf surfaces are common but not restricted to *Aniba*, but *P. coriacea* does not match any *Aniba* species I know. I regard *P. coriacea* as a name based on a monstrosity, different from the other *Persea* species reported from Surinam; for correct placement, additional specimens are needed.

I thank Dra. M. Werkhoven for making the specimen available. J. Myers drew the illustration.

THE PUBLICATIONS OF EDGAR ANDERSON: ADDITIONS

Eisendrath (1972) published a bibliography of the writings of Edgar Anderson, botanist at the Missouri Botanical Garden and Professor of Botany at Washington University for most of his career, spanning the years from 1922 until his death in 1969. For biographical information on Anderson, see Finan (1972).

The Missouri Botanical Garden Library is gathering for binding and cataloging the collected works of the curatorial staff, past and present. The following additions to the Eisendrath bibliography of Edgar Anderson have turned up:

1934. A chromosomal interchange in maize involving the attachment to the nucleolus. Amer. Naturalist 68: 345–350.

1934. Chromosomes involved in a series of interchanges in maize. Amer. Naturalist 68: 440–445. [With I. W. Clokey.]

1935. Chromosomal interchanges in maize. Genetics 20: 70–83.

1946. Christmas Eve thoughts from an herb garden. News Bulletin. New York unit of the Herb Society of America [2?]: [1].

1955. A nice quiet evening with a potato. Missouri Bot. Gard. Bull. 43(April): 50–53. (Reprinted as pp. 39–42 *in* C. B. Heiser, 1969. Nightshades, the Paradoxical Plants. W. H. Freeman and Company, San Francisco.)

1966. Islands of tension. Landscape 15: 7–8. (Reprinted in Arnoldia 48(3): 28–31. 1988.)

1967. Review of R. H. Platt, 1965, The Great American Forest. Prentice-Hall, Englewood Cliffs, New Jersey. Landscape 16: 33.

BOOK REVIEW

Flora of Australia, Volume 19. Myrtaceae—*Eucalyptus*, *Angophora*. By G. M. Chippendale, including an introduction and appendix, with contributions by D. J. Chippendale & S. G. M. Carr, A. S. George, K. D. Hill, L. A. S. Johnson, and P. J. Lang. Australian Government Publishing Service, Canberra. 1988. xvi + 543 pp., 111 figs. (38 color), 564 maps. ISBN 0-644-05866-8. Paper, price unknown.

This recently published volume of the *Flora of Australia* is the first of three that will cover that large group of trees and shrubs, the Myrtaceae. It is beautifully illustrated with numerous line drawings and seven pages of color photographs, is printed on high-quality paper, and has a good paperback binding. The volume includes a family description by A. S. George and treatments by G. M. Chippendale of the diverse genus *Eucalyptus* L'Hér. (513 species) and the much smaller *Angophora* Cav. (7 species). George calculates that there are about 75 genera and over 1,500 species of Myrtaceae in Australia. Thus, *Eucalyptus* accounts for about one third of the family there. As stated in the introduction, "more than any other group, these plants [the eucalypts] give a distinctive character to the Australian landscape." Of course, species of *Eucalyptus* are also planted around the world for ornamental and forestry purposes. Chippendale's contribution is very welcome indeed.

An informative introduction relates some of the taxonomic history of *Eucalyptus*. The last complete account was that of Blakely, *A Key to the Eucalypts* (1934), with updated editions appearing in 1955 and 1965. Until the late 1950s taxonomy was based on macroscopic characters of buds, fruits, and anthers, but since then a variety of anatomical and inflorescence features have been investigated by various workers. Presently, studies of *Eucalyptus* are appearing at an explosive rate. A quick look at the 18 issues of the *Australian Journal of Botany* for the period 1984–1986 shows that not one issue was without at least one article with *Eucalyptus* in the title and that 59 articles on *Eucalyptus* appeared, 18 of which were systematic. Thus, Chippendale's treatment is necessarily a synthesis of knowledge of *Eucalyptus* as it was in the mid 1980s, and it will soon be out-of-date. In fact, 24 species published while the book was being typeset could not be included. But considering the history of *Eucalyptus*, we cannot expect another comprehensive work soon.

Chippendale briefly reviews some of the features that have been used in systematic studies of *Eucalyptus*, viz., stamens and anthers, cotyledons, operculum, ovules, leaf waxes, oil glands, trichomes, and stigma and style morphology. However, his key to species depends on "readily-observable characters of habit, bark, leaf arrangement and form, inflorescence, buds and fruit."

Near the beginning of the volume are color photographs illustrating types of bark, habit, and various species in flower. Labeling the photographs of the various bark types would have made them more useful.

There are 60 pages of keys for *Eucalyptus*, first one dividing the species into 20 groups and then a key to the species in each group. For systematic treatment the species are divided into 92 series, but these have no close relationship to the 20 groups of species in the key. A description of each series is provided with an accompanying citation of type and notes on size, distribution, and distinguishing characteristics. There is no key to or synopsis of the series, but they are divided into groups in the introduction of the genus under the discussion of some of the systematically important characters. For each species are provided: a description of ca. 8 lines; citation of types, synonyms, and published illustrations; a figure illustrating buds and fruits; a short list of representative specimens; and notes on distribution and distinguishing characteristics. Distribution maps for all species are found on 38 pages at the end of the systematic treatment.

The style of the keys is very brief. Usually only one character comparison is made in each couplet and the alternatives can sometimes seem rather arbitrary, e.g., on page 8, lines 8 and 9 "adult leaves more than 12 cm long" versus "adult leaves less than 12 cm long"; or lines 1 and 2 on page 9—"leaves green" versus "leaves glaucous or grey green or yellow green." The very first character used in the key is bark type, and bark characters are utilized at other points in the key. I experimented by attempting to "identify" three species I know and was able to run them through the key without problem. I was less successful with identified specimens of three other species I did not know, even when I allowed myself knowledge of the bark by looking it up in the descriptions. In

my quick look at the key, I ran into one contradiction: if one takes lead "3:" on page 7, "operculum ± equal to or longer than hypanthium," one may later come to lead "100:" in group 9 on page 31, "operculum ± equal in length to, or shorter than, hypanthium."

In an appendix, Chippendale describes as new or lectotypifies several series, and nine new species included in the flora are formally published by D. J. Carr & S. G. M. Carr, L. A. S. Johnson & K. D. Hill, and P. J. Lang.

Chippendale's impressive treatment of *Eucalyptus* is sure to be a vital reference for botanists, foresters, and horticulturists. It obviously represents many years of careful study and deep familiarity with the genus. I am very happy that it has been published and recommend it to anyone with an interest in *Eucalyptus*.

Works on Orchids from the Missouri Botanical Garden

Orchids of Panama

L. O. Williams & P. H. Allen

A facsimile of the Orchidaceae, Flora of Panama, which originally appeared in four separate issues of the Annals of the Missouri Botanical Garden from 1940 to 1949. A checklist of Panama's 800 species of orchids has been prepared by R. L. Dressler and appears as an appendix. viii + 484 + xxvi pp., illustrated. 1980. $20.00.

Icones Pleurothallidinarum I: Systematics of the Pleurothallidinae (Orchidaceae)

Carlyle A. Luer

The 29 genera of this subtribe, which contains about 4,000 species, are discussed and illustrated. The introduction contains a detailed discussion of pleurothallid morphology and a key to the genera. 81 pp., color frontispiece, illustrated. 1986. $7.50.

Icones Pleurothallidinarum II: Systematics of Masdevallia (Orchidaceae)

Carlyle A. Luer

Masdevallia contains about 350 species. This overview is at the infrageneric level and includes 29 plates illustrating a representative species of each infrageneric taxon recognized. In addition, each infragenus is described and its constituent species listed. 63 pp., illustrated, color frontispiece. 1986. $6.50.

Icones Pleurothallidinarum III: Systematics of *Pleurothallis* (Orchidaceae)

Carlyle A. Luer

This work provides a guide to the genus *Pleurothallis* with keys to the subgenera, keys to the sections and subsections, and lists of representative species for each infrageneric taxon. A black and white illustration of a representative species of each genus, section, and subsection is included. 109 pp., color frontispiece, illustrated. 1986. $8.50.

Icones Pleurothallidinarum IV: Systematics of *Acostaea*, *Condylago*, and *Porroglossum* (Orchidaceae)

Carlyle A. Luer

The 33 taxa included in these pleurothallid genera are not closely related, but each has developed an actively motile labellum. In each, a stimulus by the pollinator causes the lip to rise quickly, temporarily trapping the pollinator between the lip, column, and petals. Escape requires the pollinator to brush past the stigma, rostellum, and anther. 91 pp., illustrated. 1987. $8.00.

Thesaurus Dracularum, 1 & 2

Carlyle A. Luer with Rodrigo Escobar R. German translations by Fritz Hamer. Illustrations by Stig Dalström.

Thesaurus Dracularum is a popular monograph of the genus *Dracula*. Each of the 80-odd known species is illustrated by a watercolor painting accompanied by descriptions, discussions, and distributions in both English and German, with distribution maps and black and white line drawings. In elephant-size format. Standing orders available. The first two of six fascicles. $40.00 each, postpaid.

To place an order, send check or money order in U.S. funds, payable to U.S. bank; U.S. shipments: add $1.50 for one book and $.50 for each additional book; non-U.S. shipments: add $2.50 for one book, and $.50 for each additional book. Orders should be prepaid; a $1.00 fee will be added to orders requiring invoices. No shipments are made until payment is received. Mail form with your check or money order, payable to Missouri Botanical Garden, to:

FLORA OF THE VENEZUELAN GUAYANA—VII CONTRIBUTIONS TO THE FLORA OF THE CERRO ARACAMUNI, VENEZUELA[1]

Julian A. Steyermark†, *Bruce K. Holst*,[2] *and Collaborators*

Abstract

A preliminary checklist of the vascular plant flora of Cerro Aracamuni, an isolated sandstone massif of the Roraima Shield in southern Territorio Federal Amazonas, Venezuela, is presented. The list is based on collections from five expeditions to the area. Brief comments on geography and affinities of its flora are included. Twenty-seven new taxa, including one genus, 24 species, and two subspecies are described from the massif, and three new combinations are made. The new taxa include *Ilex aracamuniana* (Aquifoliaceae); *Philodendron roraimae* subsp. *aracamuniense* (Araceae); *Pochota aracamuniana* (Bombacaceae); *Navia carnevalii*, *N. iosothrix*, *N. patria*, *N. platyphylla*, *N. terramarae* (Bromeliaceae); *Hexapterella steyermarkii* (Burmanniaceae); *Symbolanthus aracamuniensis* (Gentianaceae); *Licaria trinervis* (Lauraceae); *Tococa liesneri* (Melastomataceae); *Sauvagesia guianensis* subsp. *aracamuniensis* (Ochnaceae); *Aracamunia liesneri* (Orchidaceae); *Piper mosaicum* (Piperaceae); *Rapatea aracamuniana* (Rapateaceae); *Cephalodendron aracamuniensis*, *Coussarea liesneri*, *Neblinathamnus aracamunianus*, *Remijia reducta* (Rubiaceae); *Bonnetia liesneri*, *Ternstroemia guanchezii*, *T. maguirei* (Theaceae); *Abolboda scabrida*, *Xyris aracamunae*, *X. liesneri*, and *X. prolificans* (Xyridaceae). The three new combinations are: *Paepalanthus sulcatus* (Eriocaulaceae); *Senefeldera yutajensis* (Euphorbiaceae); and *Persea perseiphylla* (Lauraceae).

Of the sandstone massifs of the Roraima Shield, Cerro de la Neblina, on the Venezuelan–Brazilian border, to date has yielded the highest number of endemic genera and species of vascular plants. Thus its neighbors to the north and northeast, Cerro Avispa and Cerro Aracamuni, have emerged as especially interesting for botanical exploration. The first botanical collections from the summits of Cerro

[1] We thank Paul Berry, Germán Carnevali, and George Rogers for carefully reviewing the manuscript, and Luther Raechal for assistance in preparing the text. John Myers prepared several of the plates. Part of this work was supported by National Science Foundation grant BSR 8515205. We also thank the specialists who supplied determinations and descriptions. Their names are listed after each of the families whose treatments they contributed. The illustration and Latin diagnosis of *Aracamunia* were done by Bruno Manara.

[2] Missouri Botanical Garden, P.O. Box 299, St. Louis, Missouri, 63166-0299, U.S.A.

† Dr. Steyermark died on October 15, 1988. For recollections on him and a record of much of his work see the *Annals* issue 76-3.

Avispa, and apparently from Cerro Aracamuni, were made by Félix Cardona Puig and G.C.K. & E. Dunsterville on a trip with the Venezuelan Border Commission in 1972. Coordinates used by them for what they called the "Aracamuni section of Cerro Avispa" (01°30′N, 65°51′W) match very closely with those from the most recent expedition to Cerro Aracamuni. Charles Brewer Carias gathered several plants during a stop to the summit by helicopter in 1983. Small gatherings of plants from the base and slopes of Aracamuni were made on two other occasions, in 1959 from a 900-m-tall granitic outlier of Cerro Aracamuni by John Wurdack and Lincoln Adderley, and from an eastern escarpment of Aracamuni at 750 m by Otto Huber and Ernesto Medina in 1981.

Cerro Aracamuni is the largest of the table mountains closest to Cerro de la Neblina, so exploration of its summit was considered essential to help verify that the high degree of endemism reported from Neblina was not an artifact of incomplete collecting. Although the summit of Cerro Aracamuni attains an elevation of only 1,500 m, contrasted with 3,040 m on Neblina, most of the summit of Neblina lies between 1,800 and 2,200 m.

In 1987, the Terramar Foundation of Venezuela provided Ronald Liesner of the Missouri Botanical Garden and Germán Carnevali and Francisco Delascio of the Herbario Nacional de Venezuela the opportunity to explore the summit and slopes of Cerro Aracamuni between October 15 and November 3, 1987. They gathered a total of 1,018 collections (including some bryophytes and fungi, which are not considered in this paper) from the summit and slopes.

Cerro Aracamuni lies near the southern tip of Territorio Federal Amazonas, Venezuela, in Dept. Río Negro, approximately 125–140 km northeast of Cerro de la Neblina (Fig. 1). It is a small to medium-sized massif for the Guayana region, rather long and narrow with a north-to-south orientation, extending from 01°24′N, 65°47′W to 01°32′N, 65°49′W. Vertical sandstone escarpments flank some of the sides, and a few rock outcrops appear on the upper edges. From its summit, streams drain into the Matapire and Siapa rivers on the east, north, and south, and into the Río Yatúa on the west. Several kilometers of lowland rainforest extend on the Río Siapa side to the base of the massif. The large rapids, Raudal and Salto Gallineta, are prominent topographic features on the igneous outcrops along the Río Siapa. Most of the massif is believed to be of Roraima sandstone.

A close relationship with the flora of Cerro de la Neblina is expected on Cerro Aracamuni due to the proximity of the two massifs. Four of the genera previously known only from Cerro de la Neblina, *Neblinanthera*, *Celiantha*, *Cephalodendron*, and *Neblinathamnus*, are now known from Cerro Aracamuni as well. Species (and subspecies) previously known only from Neblina, and now recorded from Aracamuni, are: *Sobralia speciosa* C. Schweinf., *Endlicheria vinotincta* Allen, *Spathelia neblinaensis* R. Cowan & Briz., *Diacidia glaucifolia* (Maguire) W. R. Anderson, *Philacra auriculata* Dwyer, *Tyleria silvana* Maguire, *Maieta neblinensis* Wurd., *Neblinanthera cumbrensis* Wurd., *Tococa pachystachya* Wurd., *Orthaea wurdackii* Maguire, Steyerm. & Luteyn, *Celiantha bella* Maguire & Steyerm., *Faramea boomii* Steyerm., *Ferdinandusa neblinensis* Steyerm., and *Pagameopsis maguirei* subsp. *neblinensis* Steyerm.

Two additions to the Venezuelan flora from the Aracamuni expeditions are *Tyleria silvana* Maguire, previously known from the Brazilian side of Cerro de la Neblina and Serra Pirapucú, and an as of yet unidentified species of the genus *Jacqueshuberia*, previously known only from Amazonian Brazil and Colombia.

Vegetation of the Summit

The summit is covered mostly by 0.5–1-m-high, dense savanna (non-Poaceae) and low shrub vegetation, and small forested areas occur in depressions and along streams. The savanna is inhabited mostly by Eriocaulaceae, Rapateaceae, Bromeliaceae, Xyridaceae, Liliaceae, and Sarraceniaceae. Common shrubs and small trees of the savanna include *Poecilandra retusa*, *Pagameopsis maguirei* subsp. *neblinensis*, *Bonnetia tristyla*, *Distictella monophylla*, *Emmotum glabrum*, and *Gongylolepis huachamacari*. The patches of forest and gallery forest include *Neblinanthera cumbrensis*, *Aegiphila roraimensis*, *Clusia* sp., *Diacidia glaucifolia*, *Phyllanthus vacciniifolius*, *Psychotria duricoria*, *P. tapajozensis*, and *Tyleria silvana*.

The remainder of this paper is divided into two sections, descriptions of new taxa and presentation of new combinations, and the preliminary checklist of the flora of Cerro Aracamuni.

New Taxa and Combinations from Cerro Aracamuni

Aquifoliaceae—contributed by Julian Steyermark

Ilex aracamuniana Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Proa

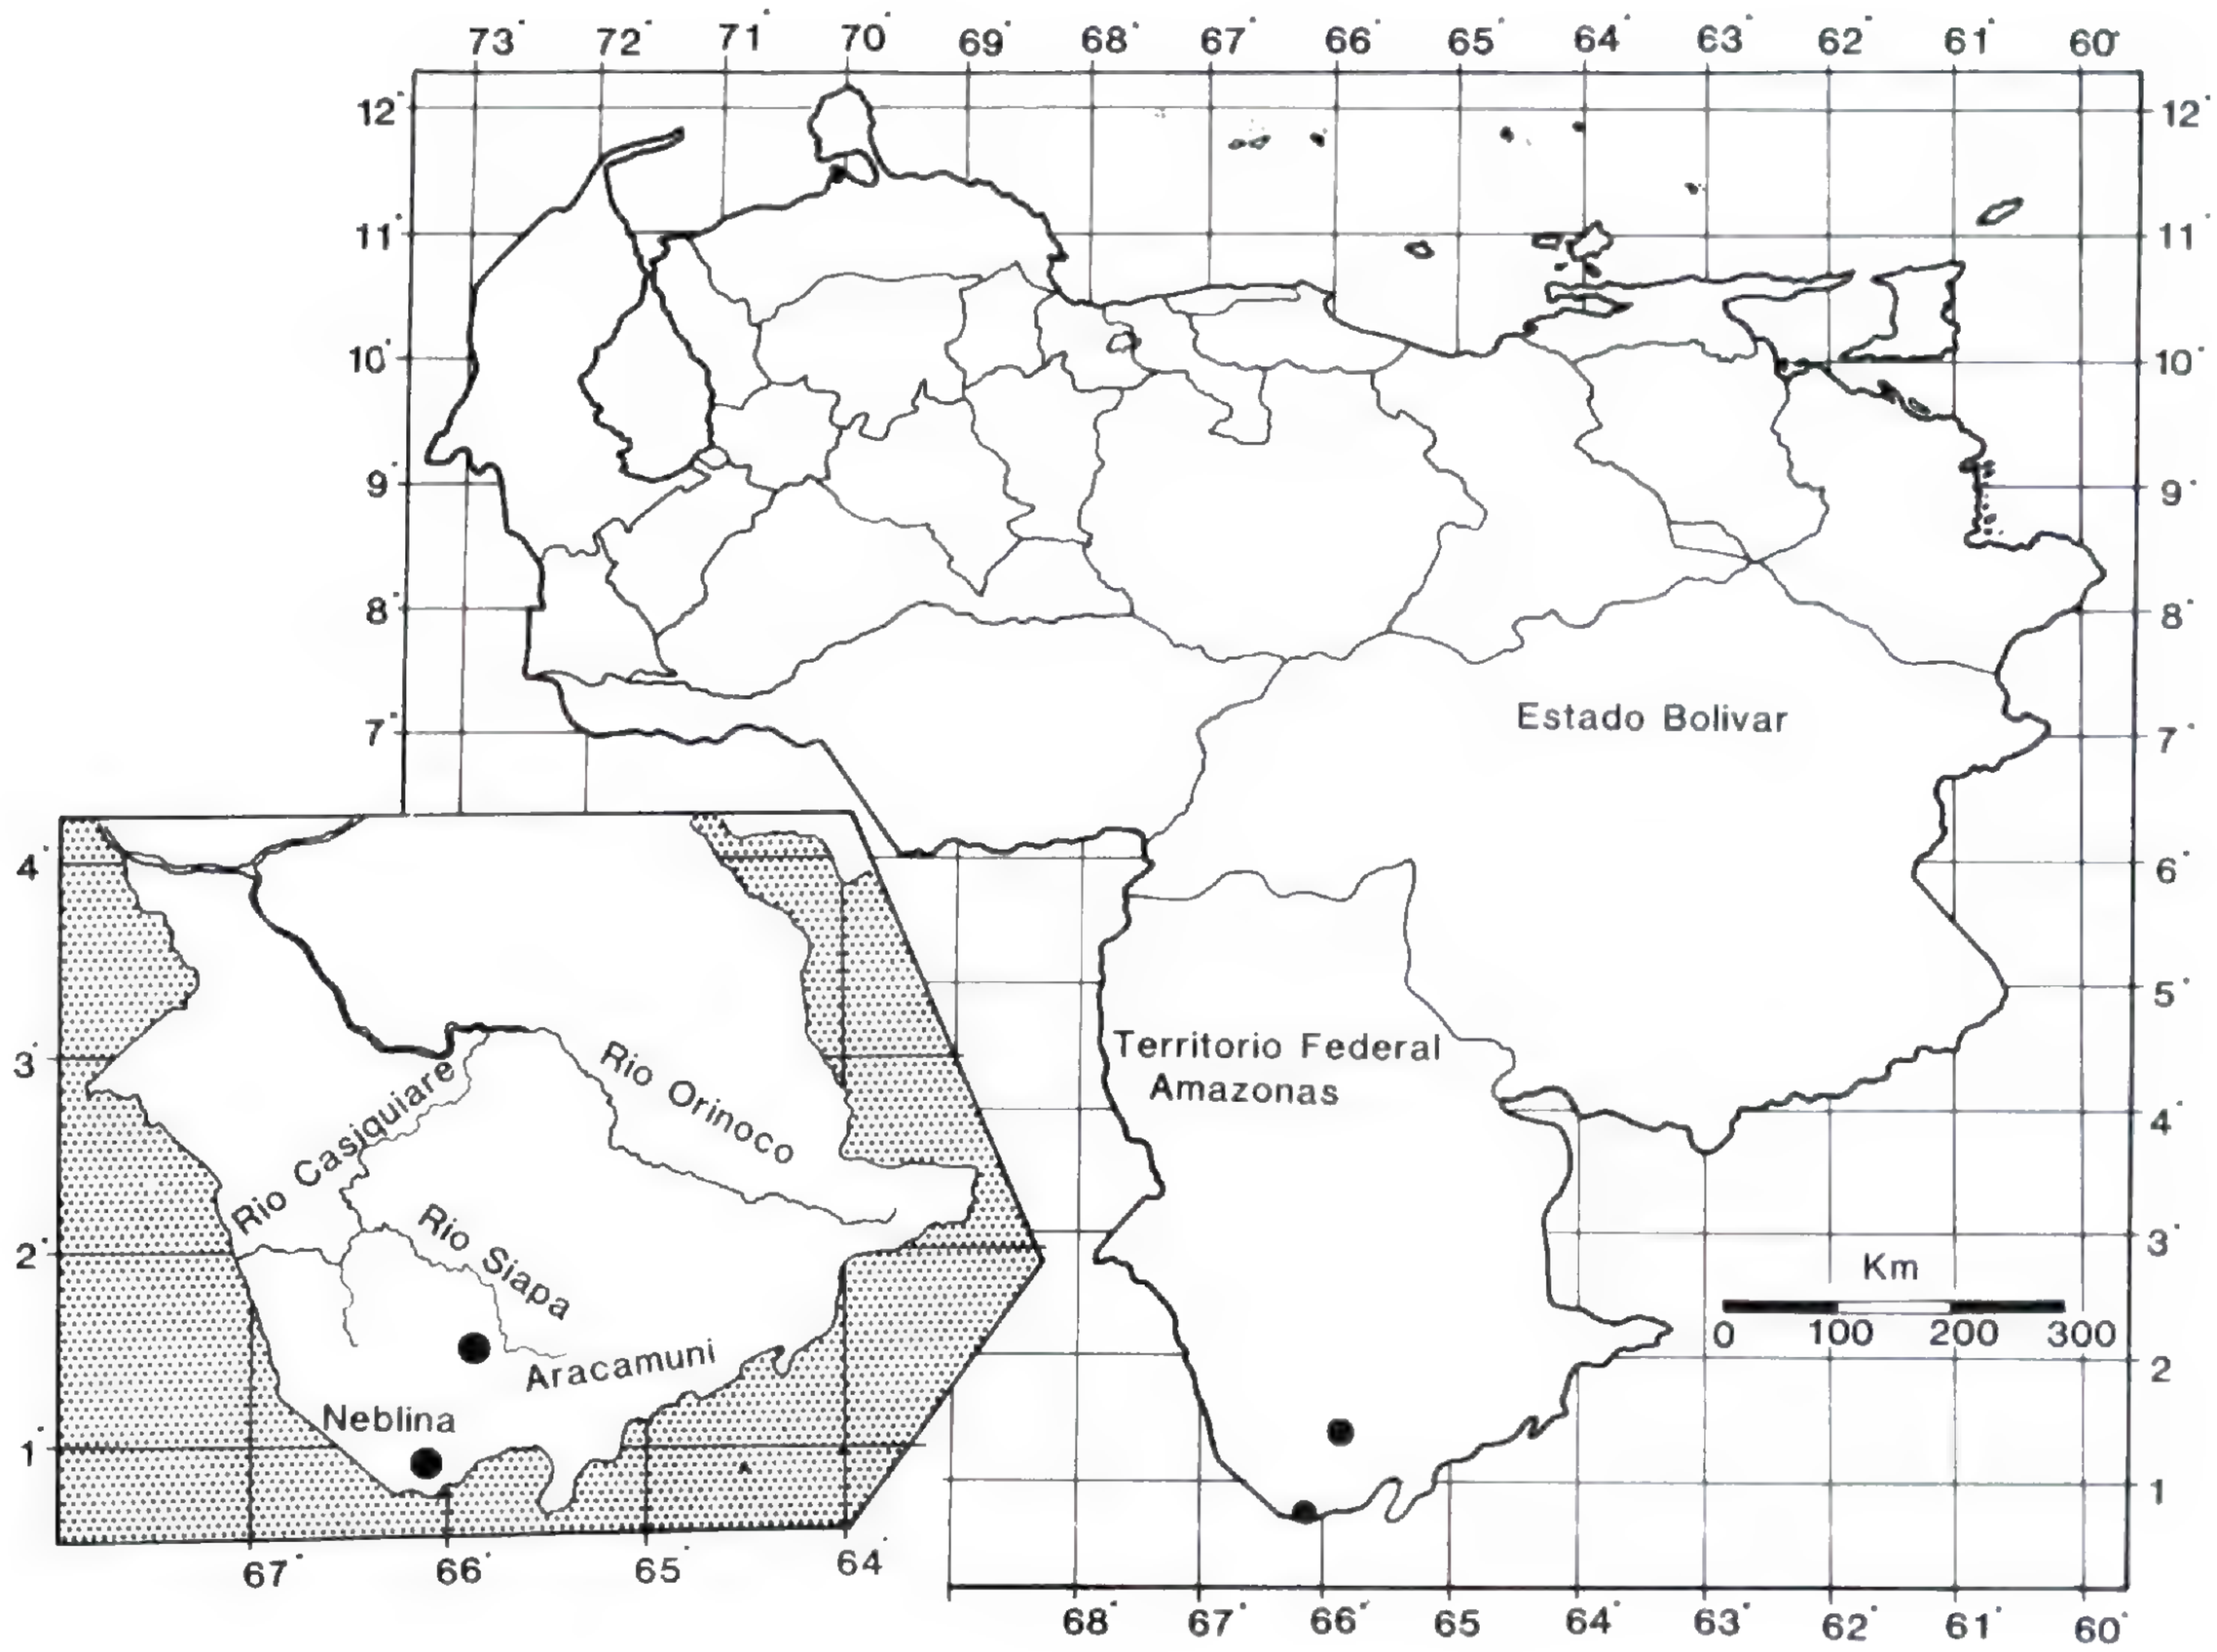

FIGURE 1. Map of Venezuela with détail of southern Territorio Federal Amazonas.

Camp, medium height, semi-open forest, 01°32′N, 65°49′W, 1,400 m, 26 Oct. 1987, *R. Liesner & G. Carnevali 22473* (holotype, MO; isotype, VEN). Figure 2.

Arbor 6–10-metralis; foliorum laminis lanceolato- vel oblongo-ellipticis apice obtuse acutis basi acutis 6.5–10 cm longis (1.7–)2–3.5(–4) cm latis ubique glabris subtus atropunctatis, valde decurrentibus, nervis lateralibus utroque latere 5–7 subtus impressis haud conspicuis, venatione tertiaria tenuiter reticulatis; petiolis 6–12 mm longis; inflorescentia foeminea solitaria axillari lateralique; pedicellis foemineis maturis 13–16 mm longis; calycis lobis breviter suborbicularibus apice acutis vel acuminatis; fructu subgloboso maturo 8–10 × 8–10 mm; pyrenis quinque trigonis 6 mm longis dorsaliter unisulcatis.

Tree 6–10 m tall, glabrous throughout. Leaf blades coriaceous, lance- to oblong-elliptic, obtusely acute at apex, acute at base, 6.5–10 cm long, (1.7–)2–3.5(–4) cm wide, dark punctate below, strongly decurrent on the petiole; midrib narrowly sulcate above, elevated below; lateral nerves 5–7 each side, slightly sulcate above, impressed but not strongly conspicuous below, ascending at 45–50°, inconspicuously anastomosing 2–4 mm from the margin; tertiary venation subimpressed and grossly reticulate above, finely reticulate below with impressed venation. Petioles 6–12 mm long, winged by the decurrent leaf bases. Pistillate inflorescence solitary, axillary and lateral; pedicels in post-anthesis 7–11 mm long, 13–16 mm long in fruit. Calyx lobes in anthesis triangular, acuminate or slenderly acute, in fruit broadly ovate and abruptly acute at apex. Fruit subglobose at maturity, 8–10 × 8–10 mm; pyrenes 5, 6 mm long, trigonal, unisulcate dorsally. Stigmatic lobes in post-anthesis prominent, discoid-capitate, 1 mm high, 1 mm diam.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, edge of tepui in ravine, 01°26′N, 65°42′W, 1,550 m, 19 Oct. 1987, *R. Liesner & F. Delascio 22181* (MO, VEN); *R. Liesner & F. Delascio 22060* (MO, VEN).

This species is related to *Ilex sipapoana* Edwin and *I. huachamacariana* Edwin. It differs from the former in the longer mature pedicels; prominently decurrent leaf bases; and leaf blades with an obtusely acute apex, less conspicuous reticulation of the abaxial tertiary venation, and fainter

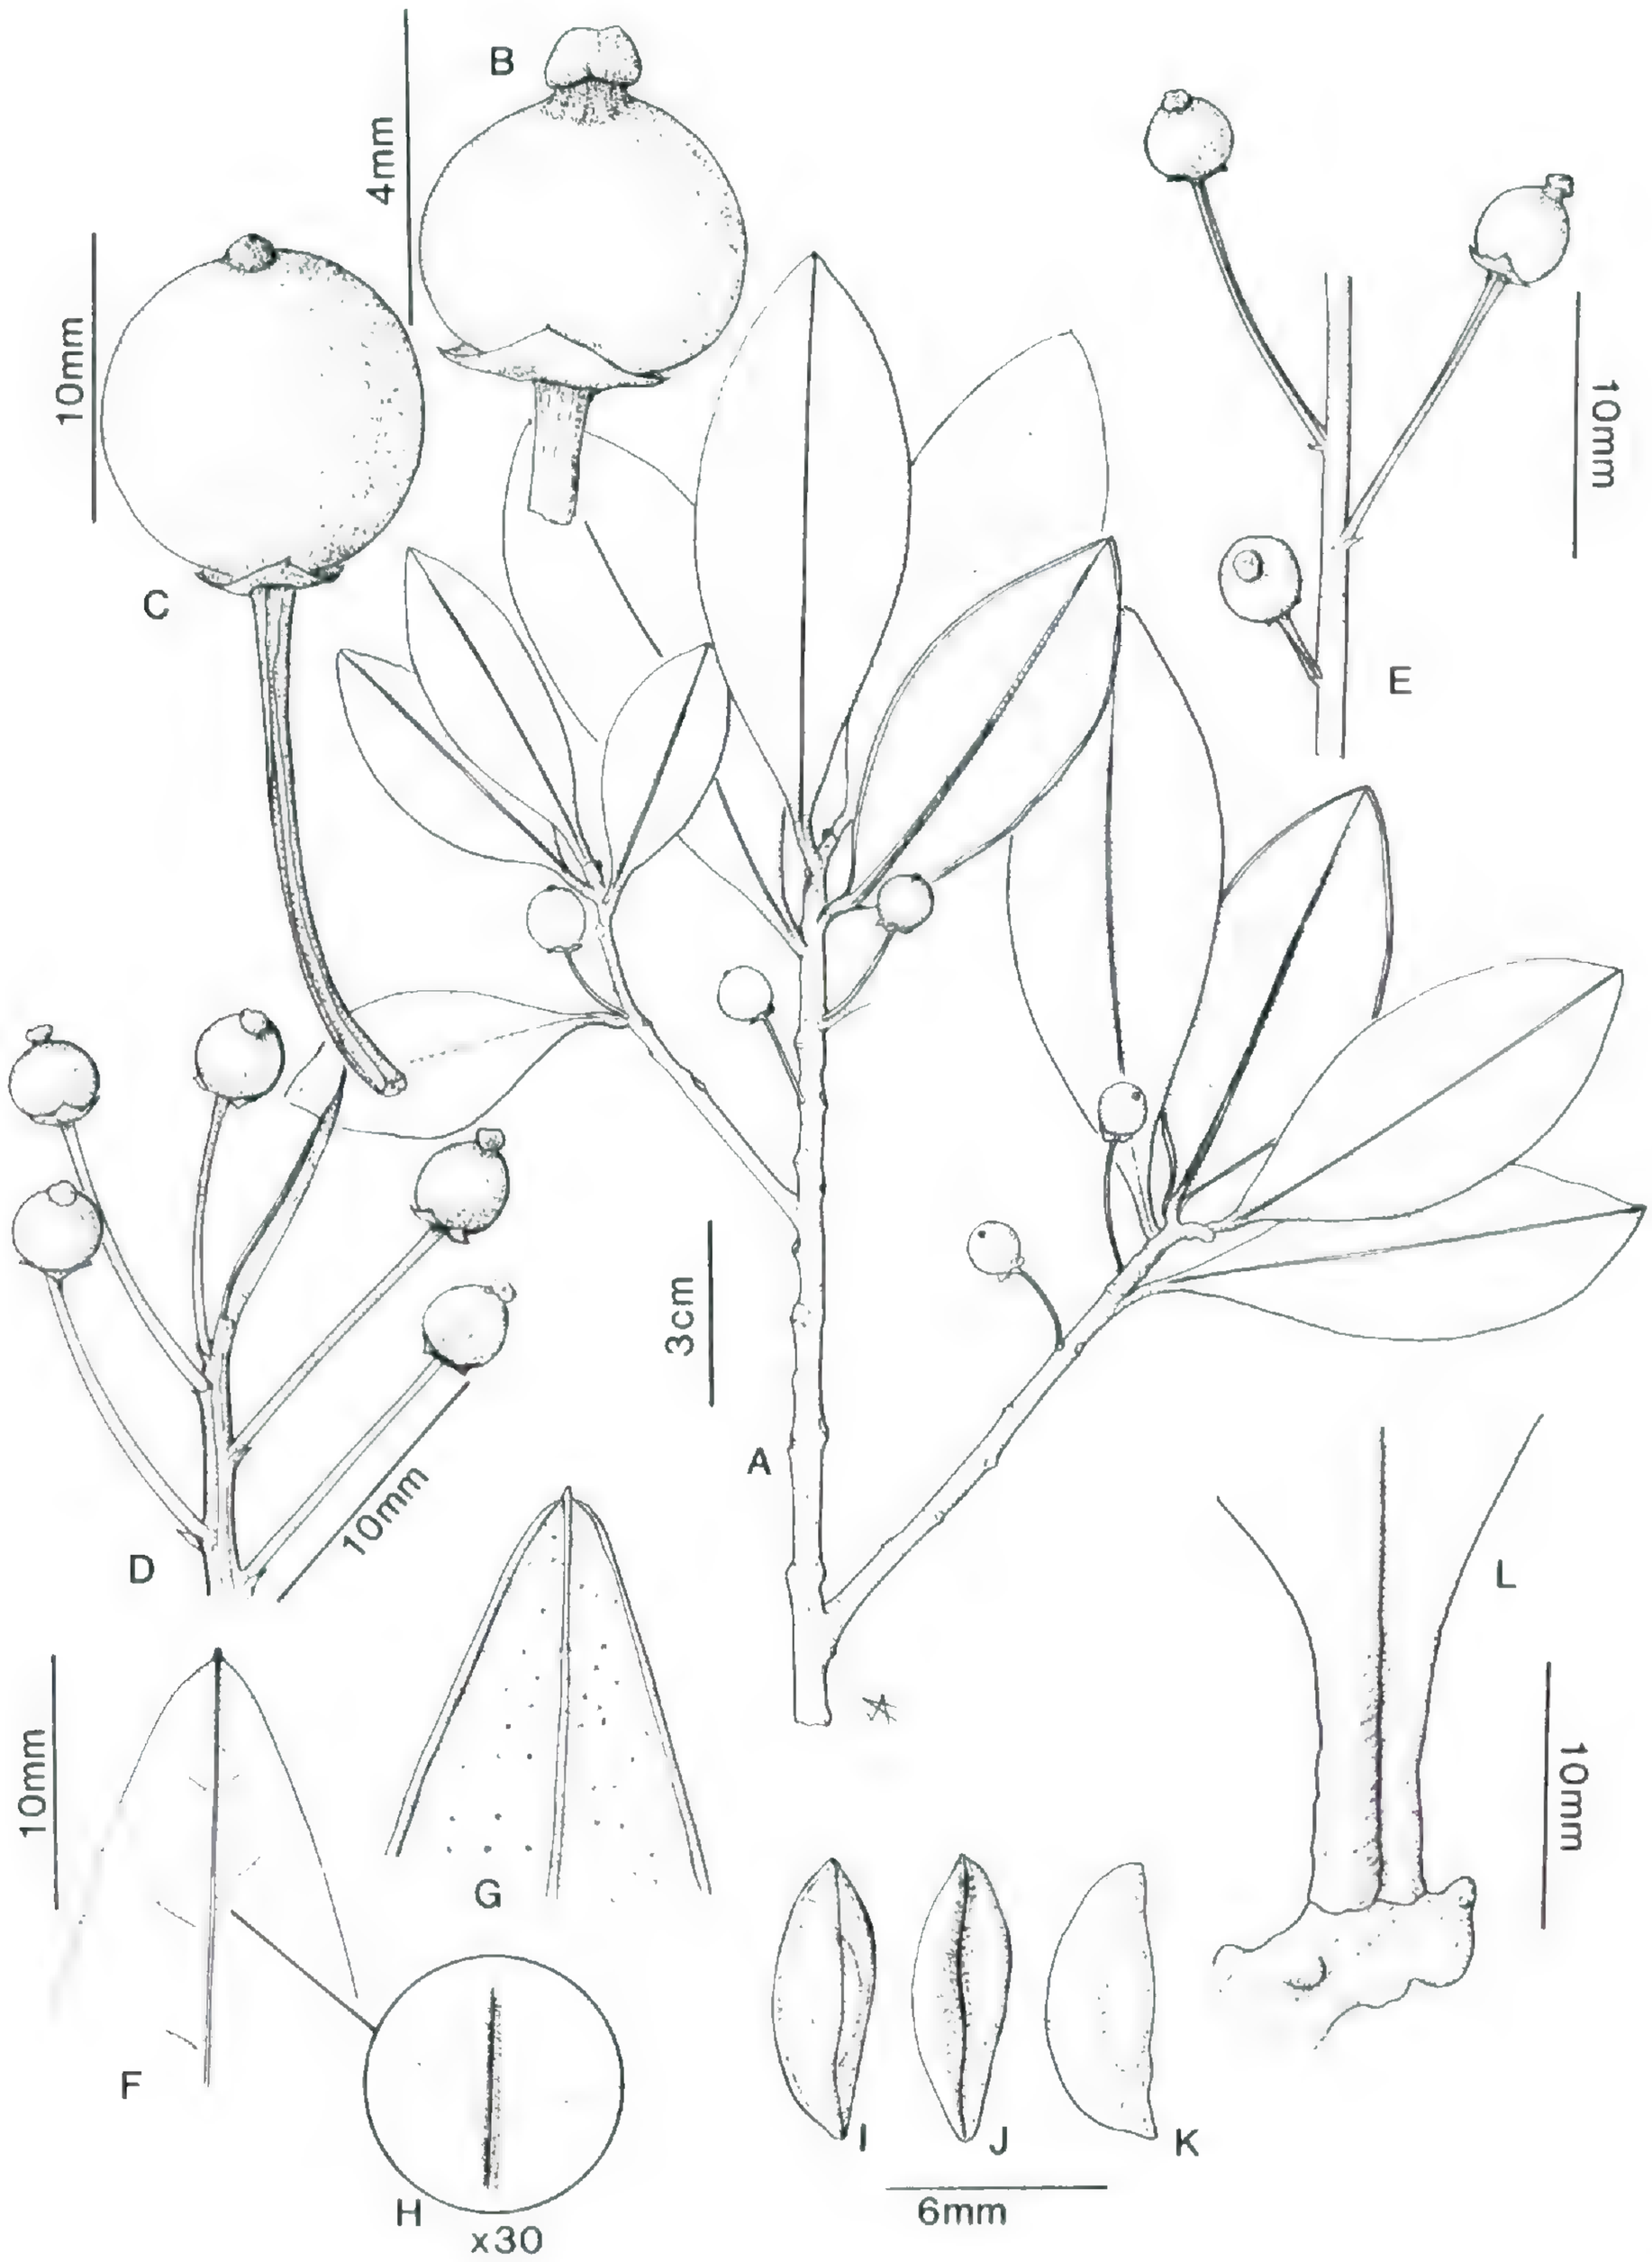

FIGURE 2. *Ilex aracamuniana*.—A. Habit.—B. Immature fruit.—C. Mature fruit.—D, E. Fertile stem.—F. Leaf tip, upper surface.—G. Leaf tip, lower surface.—H. Detail of upper leaf surface.—I, J, K. Seed.—L. Detail of petiole. (A, C–L, from *Liesner & Carnevali 22473*; B, from *Liesner & Delascio 22181*.)

lateral nerves of the lower surface. The new species differs from *I. huachamacariana* by having longer petioles and broader leaf blades not retuse at the apex.

ARACEAE—contributed by George Bunting

Philodendron roraimae K. Krause subsp. **aracamuniense** Bunting, subsp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, Proa Camp, in medium height semi-open forest, 01°32′N, 65°49′W, 1,400 m, 26 Oct. 1987, *R. Liesner & G. Carnevali 22510* (holotype, MO). Figure 3.

A subspecies typica foliorum lamina aliquantum minore et minus crassa et proportione angustiore, petiolo tereti (fide collectorum) abhorret.

Climbing herb. Stem to 5 m long, terminal part

FIGURE 3. *Philodendron roraimae* subsp. *aracamuniense* (*Liesner & Carnevali 22510*).

hidden by mass of coarsely fibrous cataphyll remains. Cataphyll broad, to 24 cm long, marcescent. Petiole stout, terete, 50–57(–68?) cm long in vivo with many lines of small gray dots. Leaf blade coriaceous though easily fracturing along veins, ovate (narrowly triangular in juvenile shoots), 44–54 cm long, 27–ca. 40 cm wide (1.4–1.6 times longer than wide), apex obtuse and abruptly acuminate, 1–1.5 cm long; posterior lobes introrse, rounded at apex or somewhat angular but very blunt, slightly overlapping and enclosing a subrhombic space 5 cm long, or separated by a ± mitriform sinus 14–18 cm long; margins undulate; midrib wide and prominent, primary lateral veins adaxially sulcate and abaxially raised, ca. 6–7 per side arising at angles of ca. 55–65°; lesser veins all manifest and abaxially raised; posterior lobes with 2 primary lateral veins on each side of basal ribs, the latter nude in sinus for ca. 2–3.5 cm. Inflorescence solitary. Peduncle 4.5 cm long. Spathe

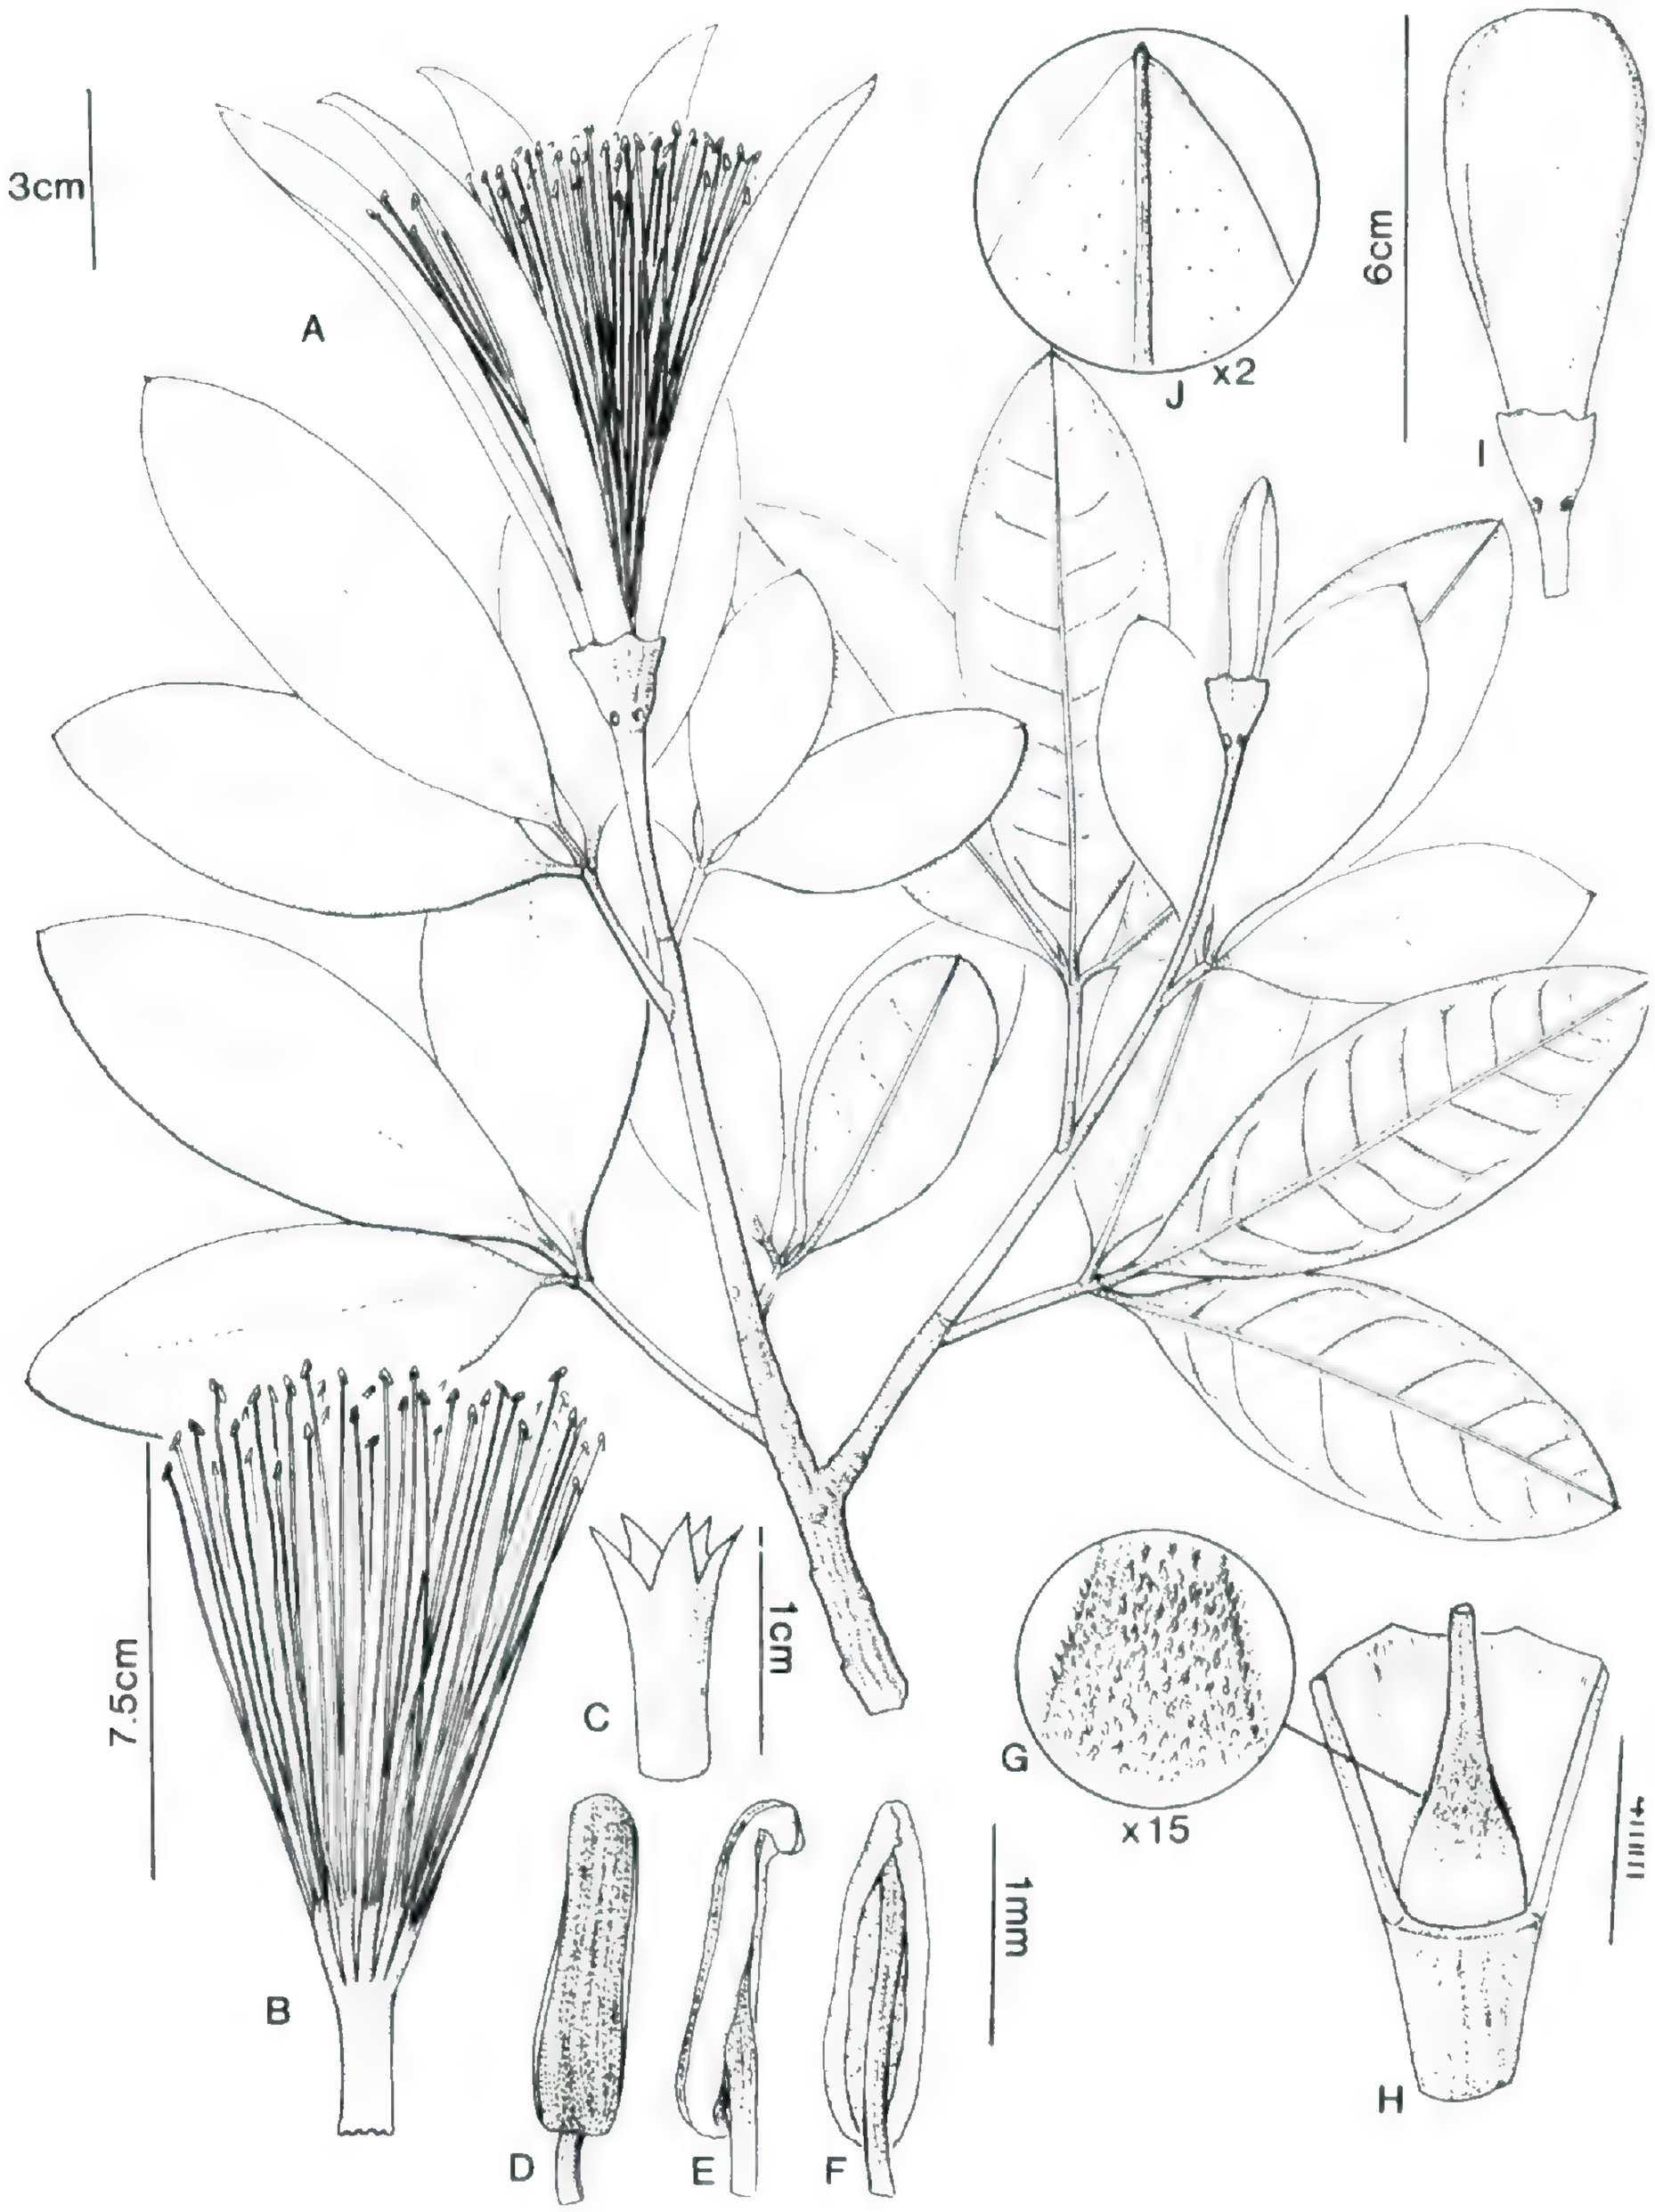

FIGURE 4. *Pochota aracamuniana*.—A. Habit of branch.—B. Androecium.—C. Staminal tube.—D, E, F. Anther.—G. Detail of style base, ovary summit.—H. Ovary and base of style.—I. Fruit.—J. Detail of lower leaf surface. (A–H, J, from *Liesner & Carnevali 22559*; I, from *Liesner & Carnevali 22577*.)

stout, 15–17 cm long, not constricted, outside with tube red and limb yellowish. Spadix 12.5–14.5 cm long, pistillate part 4 cm long and 2–2.5 cm thick, staminate part 8.5–10 cm long with sterile part to 4.5 cm and fertile part to 5.5 cm long. Ovary 3–5-locular, locules each with 6–8 or more ovules apparently superposed from bottom to top.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, Popa Camp, savanna with small to large patches of forest and stream, 01°26′N, 65°47′W, 1,550 m, 16 Oct. 1987, *R. Liesner & F. Delascio 21956* (MO).

The characters that separate the two subspecies of *P. roraimae* are few, yet the specimens seem quite distinct at first glance, chiefly because of the proportionally narrower leaf blade of subsp. *aracamuniense*. Even the juvenile leaves of both taxa have a similar, narrow blade outline. An important difference may prove to be petiole shape, said to be terete in the Aracamuni collections; in the ma-

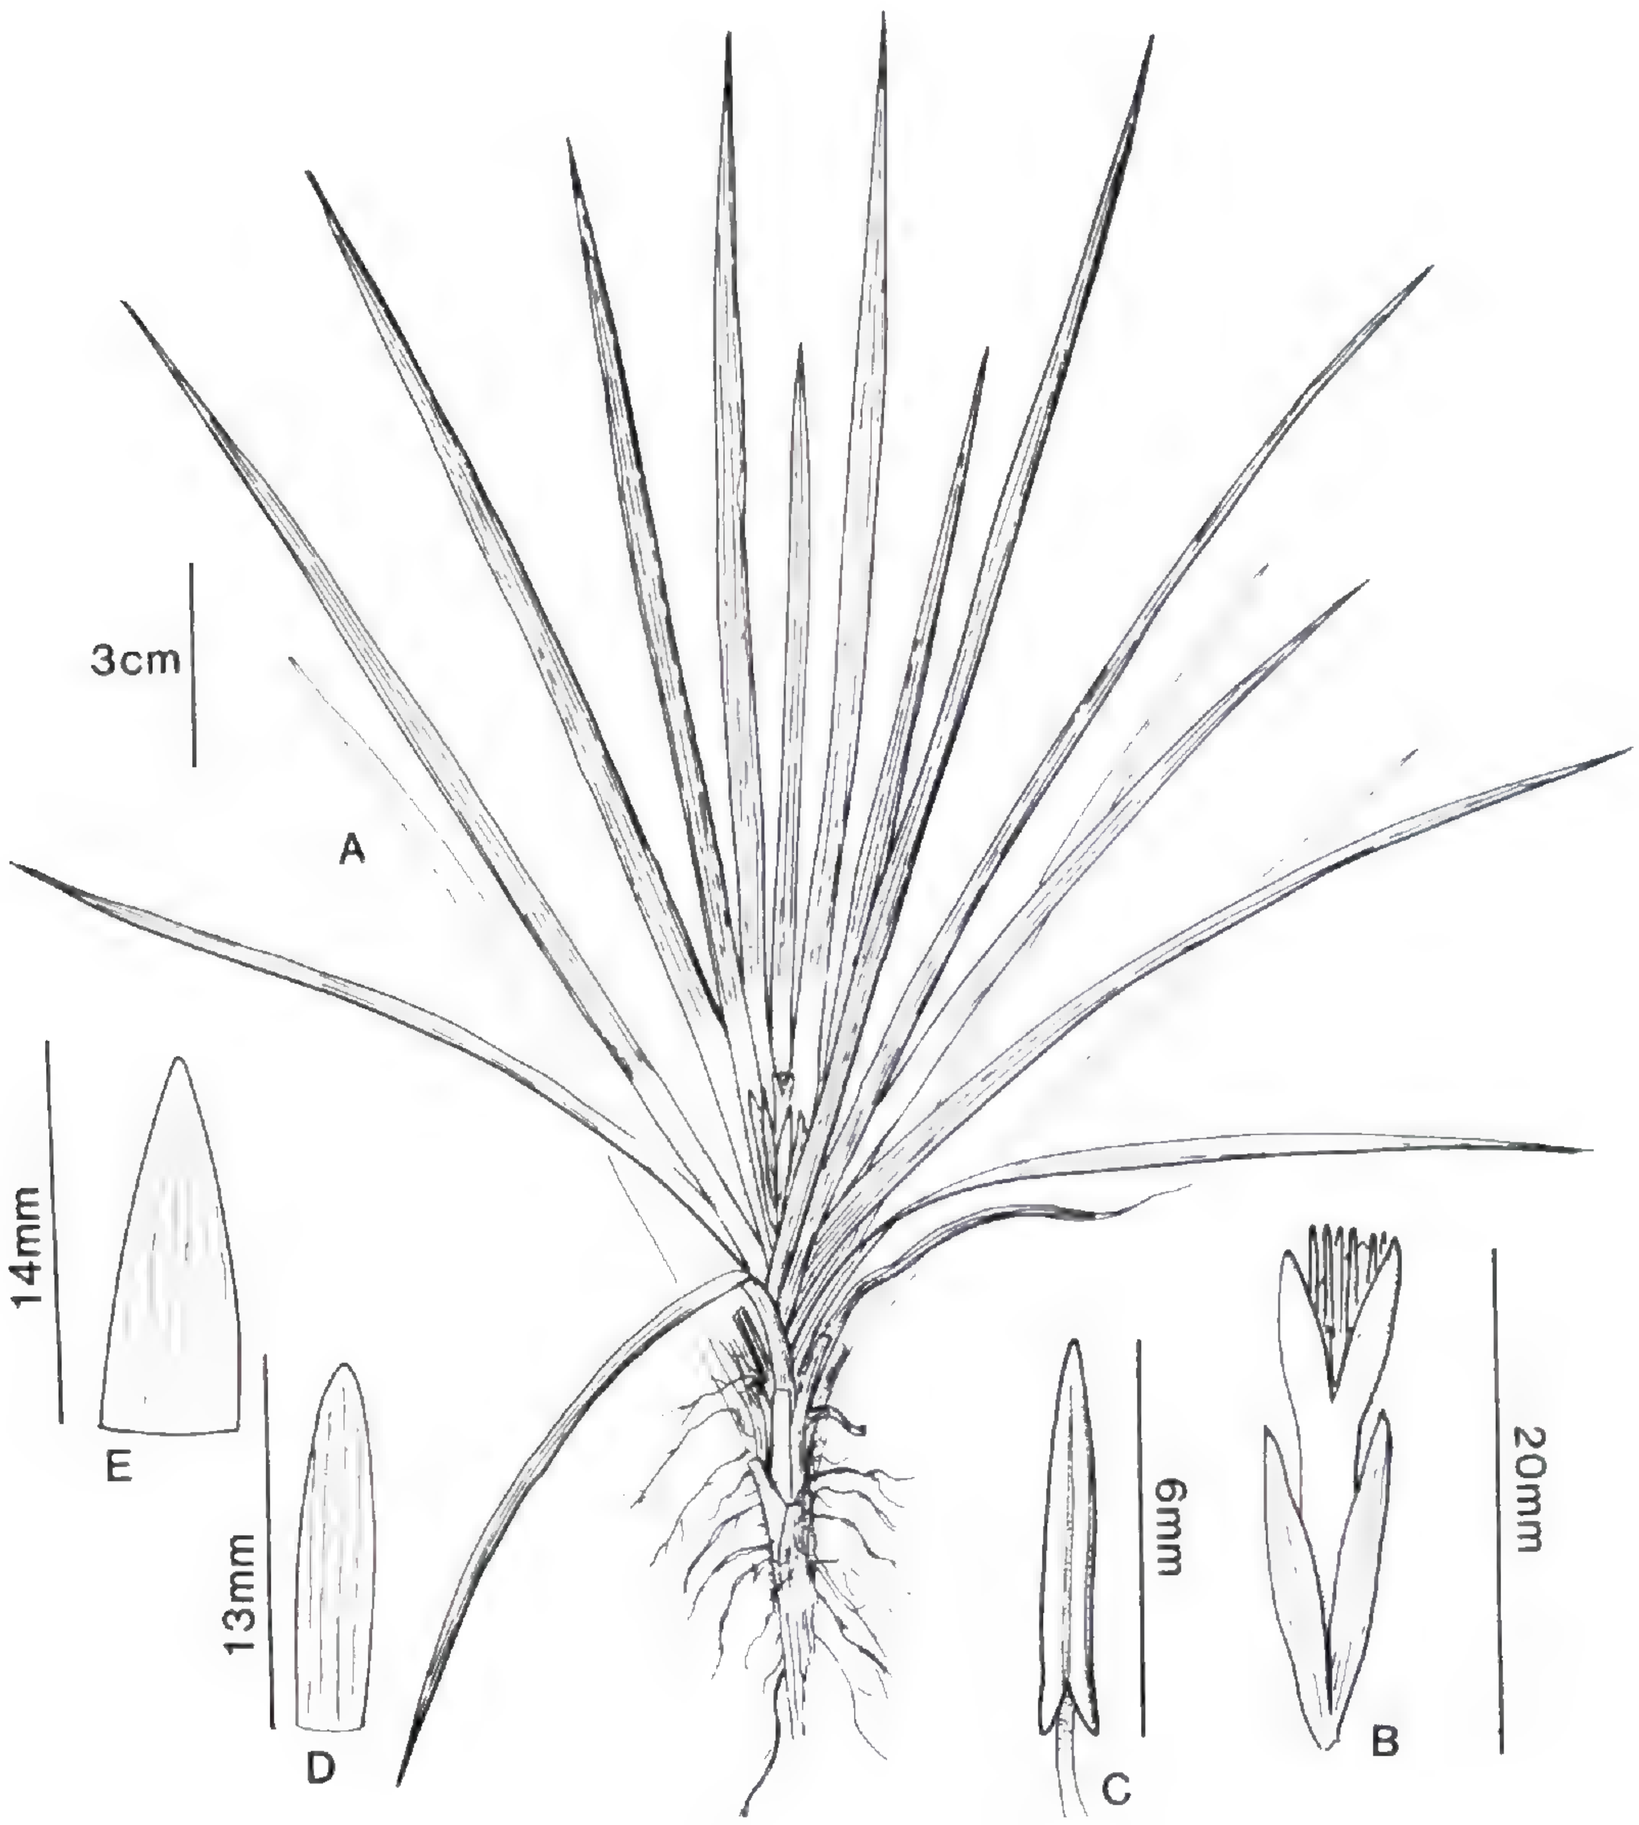

FIGURE 5. *Navia carnevalii.*—A. Habit.—B. Flower.—C. Anther.—D. Sepal.—E. Floral bract. (From *Liesner & Delascio 22322.*)

terial of subsp. *roraimae* from the Gran Sabana, it is rounded abaxially, while the adaxial surface has a median, longitudinal, obtuse angle (ridge) and two plane faces.

This is the common *Philodendron* growing on the summit of Cerro Aracamuni, climbing up tree trunks. Its relation to *P. nebulense* Bunting (described from Cerro de la Neblina) remains to be determined when fertile material of the latter becomes available.

BOMBACACEAE—contributed by Julian Steyermark

Pochota aracamuniana Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, semi-open forest at edge of forest, 01°32′N, 65°49′W, 1,400 m, 28 Oct. 1987, *R. Liesner & G. Carnevali 22559* (holotype, MO; isotype, VEN). Figure 4.

Arbor 3–6-metralis; foliis (1-)3-foliolatis, foliolis elliptico-oblongis vel lanceolato-ellipticis apice obtusis vel subobtusis minute mucronatis basi acutis vel subacutis, majoribus 6–10.5 cm longis 2–3.7 cm latis subtus atrolepidotis; petiolis 1.5 2 cm longis, petiolulis 4 8 (–13) mm longis; petalis 8–11 cm longis 7–15 mm latis; tubo staminali 10–11 mm longo praeter basin versus minute papillatum glabro; filamentis 6–7.5 cm longis; stylo basi lepidoto parte inferiore 4.2 cm atroglandulari parte superiore 4 cm glabro.

Tree 3–6 m tall. Leaves (1-)3-foliolate, leaflets coriaceous, elliptic-oblong to lance-elliptic, obtuse or subobtuse at apex with a minute mucro, acute to subacute at base, 6–10.5 cm long, 2–3.7 cm wide, densely dark brown lepidote beneath; midrib sulcate above, elevated below; lateral nerves impressed and manifest above, conspicuously impressed below, anastomosing 2–3 mm from margin; tertiary venation impressed above, subreticulate below. Petioles 1.5–2 cm long; petiolules 4–8(–13) mm long. Pedicel 2–3.5 cm long. Receptacle dark glandular. Calyx campanulate, 5–8 mm long (dried), to 12 mm (living), 10–12 mm wide at summit in anthesis, subundulate, minutely mucronate at sum-

mit, dark glandular-lepidote without, sericeous within. Petals linear-ligulate, 8–11 cm long, 7–15 mm wide, canescent-lepidote on both sides. Stamens ca. 110, in 5 principal phalanges. Staminal tube 10–11 mm long, glabrous except for minute papillation basally; filaments 6–7.5 cm long; anthers 1–2.5 mm long. Style 8.2 cm long, sparsely dark glandular-lepidote in lower 4.2 cm, lepidote at very base, glabrous in the upper 4 cm. Ovary ovoid-deltoid, 4 × 3.5 mm, glabrous below, lepidote above. Fruit narrowly obovate, truncate-rounded at summit, 6 cm long, 2.5 cm wide at summit, minutely dark lepidote.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, edge of savanna, 01°32′N, 65°49′W, 1,400 m, 28 Oct. 1987 (ft), *R. Liesner & G. Carnevali 22577* (MO, VEN); Cerro Aracamuni, summit, Popa Camp, savanna at edge of forest, 01°26′N, 65°47′W, 1,550 m, 19 Oct. 1987, *R. Liesner & F. Delascio 22174* (MO, VEN).

This species is related to *Pochota robynsii* Steyerm., but differs by having broader petals; generally obtuse, elliptic leaflets with a mucronulate apex; and conspicuous secondary nerves and tertiary venation.

BROMELIACEAE—contributed by Lyman B. Smith & Julian Steyermark

Navia carnevalii Lyman B. Smith & Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, Quebrada Camp, laja area, 01°24′N, 65°38′W, 600 m, 22 Oct. 1987, *R. Liesner & F. Delascio 22322* (holotype, US; isotypes, MO, VEN). Figure 5.

A *N. umbratile* Lyman B. Smith, cui valde affinis, foliorum laminis subintegris glabris, bracteis florigeris anguste oblongis vel oblongo-lanceolatis glabris differt.

Plant shortly caulescent, the stem variable in length, 1–6 cm long. Leaf sheaths brown, 1.5–2 cm long, 5–10 mm wide, many ribbed. Leaf blades white at base, suberect, linear, attenuate, not contracted at base, coriaceous, 9–21 cm long, 3–5 mm wide, glabrous above, minutely inconspicuously lepidote below, margins thickened, subinvolute, subentire. Inflorescence 2–3-flowered, enclosed within the bracts, narrowly lanceolate, 2.5 cm long, 2–3 cm wide. Outer bracts foliaceous, linear, to 6 cm long, 1–2 mm wide. Floral bracts membranous, narrowly oblong or oblong-lanceolate, acuminate, about equaling the sepals, 13–14 mm long, 4 mm wide. Sepals free, keeled, conduplicate, lanceolate, 12–13 mm long, 3 mm wide, glabrous, obtusely narrowed to a slightly incurved, slightly mucronate tip. Corolla white, 20 mm long, with a narrow cylindric tube, 12 mm long, the lobes lanceolate, subacute, 6–7 mm long, 2–2.5 mm wide. Ovary superior.

The subentire leaves and the narrowly oblong or oblong-lanceolate, acuminate floral bracts distinguish this species from *N. umbratilis* Lyman B. Smith of Cerro Yutajé.

Navia iosothrix Lyman B. Smith & Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, riverbank in shade of forest, Quebrada Camp, in area of rapids flowing over laja, 01°24′N, 65°38′N, 600 m, 20 Oct. 1987, *R. Liesner & F. Delascio 22203* (holotype, US; isotypes, MO, VEN). Figure 6.

A speciebus omnibus adhuc cognitis a conjunctione inflorescentiae parvi globosae pauciflorae, bracteae primariae valde reductae haud foliaceae, sepalorum minimorum lateralium verisimiliter librorum cucullatorum differt.

Plant caulescent with a short thickened stem 5–7 cm long, in a dense spreading rosette. Leaf sheaths oblong-ovate, slightly broader than and merging into the leaf blades, 13–20 mm long, 13–15 mm wide, many-nerved. Leaf blades divaricately spreading, with a median stripe, linear, long-attenuate, 15–23 cm long, 10–13 mm wide, minutely serrulate throughout with teeth ca. 0.2 mm long, minutely and sparsely lepidote on both surfaces, especially beneath. Infructescence simple, sessile, subglobose-ovoid, many-flowered, 1.5–1.8 cm high, 1.5–1.7 cm diam., ferruginous-tomentellose. Outer bracts few, not foliaceous, strongly reduced, 2.5–3 cm long, 4–5 mm wide, serrulate. Smaller lateral sepals apparently free, cucullate. Ovary superior. Capsule broadly ovate, 6.5 mm long; seeds blackish brown, 0.8 mm long, verruculose, costate, finely reticulate.

The strongly reduced, nonfoliaceous primary bracts, together with the smaller, free, cucullate lateral sepals and ferruginous tomentose infructescence distinguish this species. The specific name refers to the rusty-colored hairs of the infructescence.

Navia patria Lyman B. Smith & Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, crevice of bluff at edge, savanna with small to large patches of forest and stream, 1°26′N, 65°47′W, 1,550 m, 17

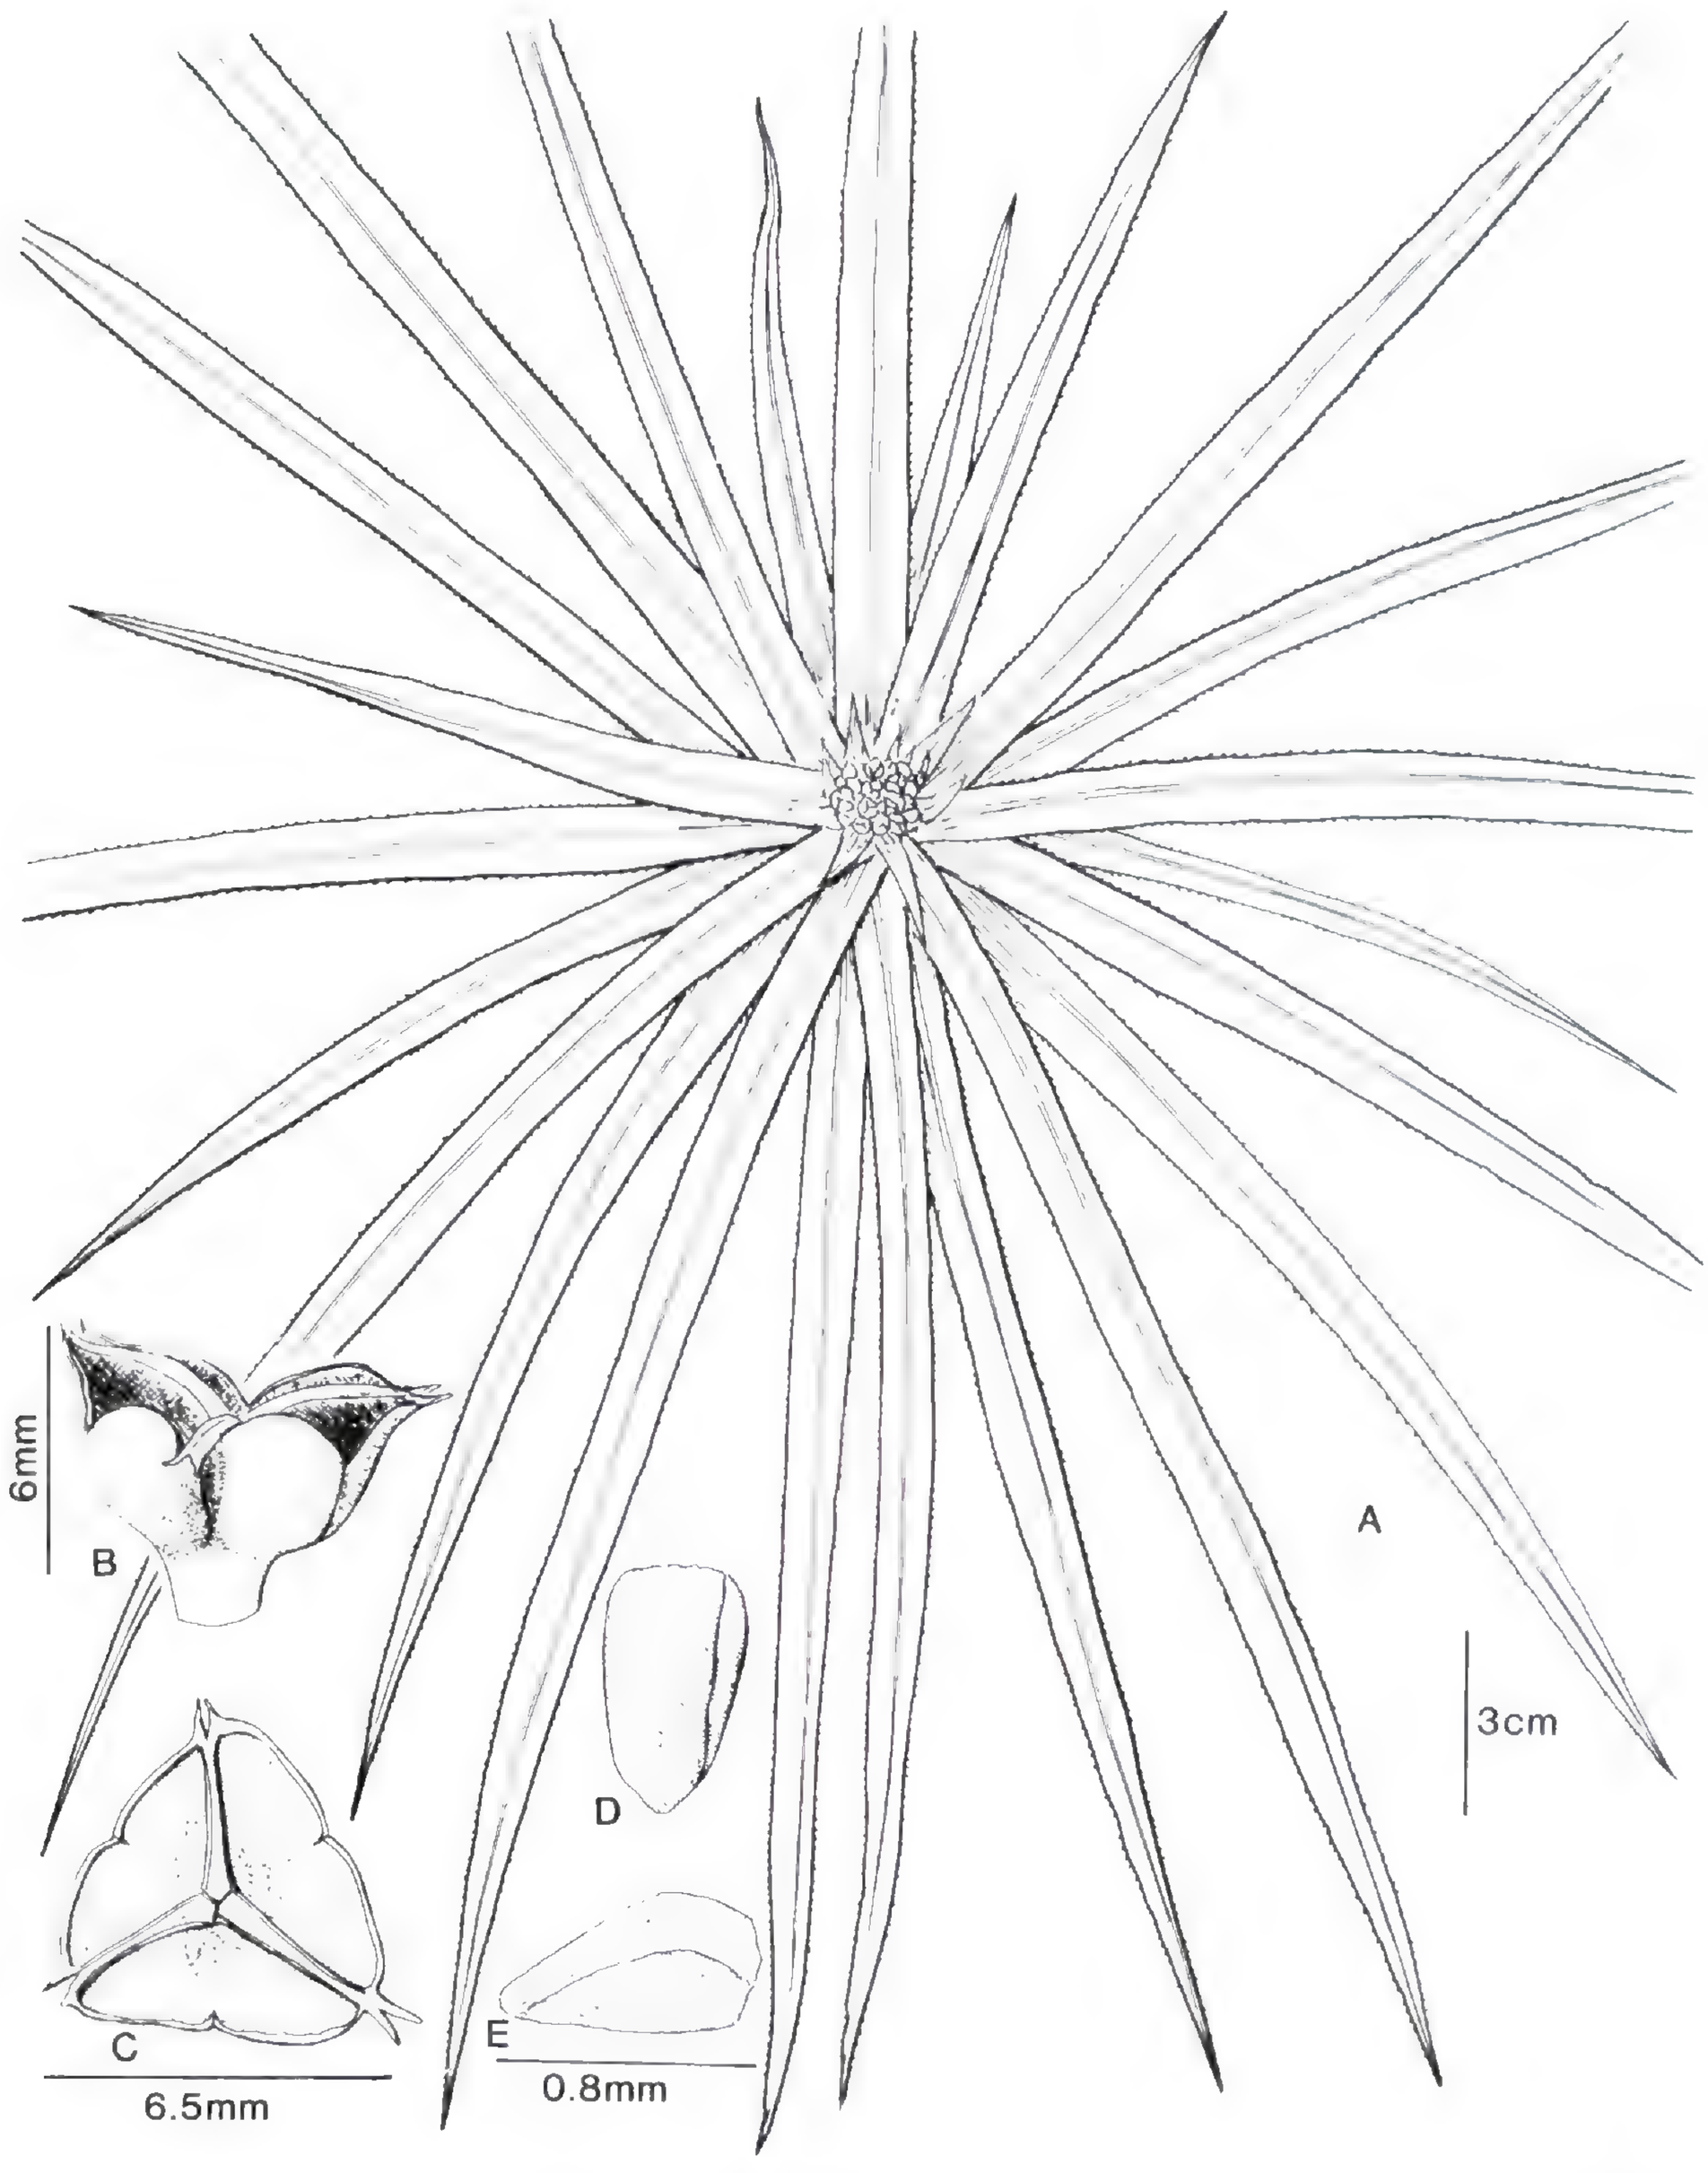

FIGURE 6. *Navia iosothrix.*—A. Habit.—B. Fruit, lateral view.—C. Fruit, view from above.—D, E. Seed. (From *Liesner & Delascio 22203.*)

Oct. 1987, *R. Liesner & F. Delascio 22041* (holotype, US; isotypes, MO, VEN). Figure 7.

A *N. crispa* Lyman B. Smith, cui valde affinis, foliorum laminis haud crispatis, bracteis primariis paulo reductis basi pallidis, bracteis florigeris acutis, multo majoribus differt.

Plant in dense spreading rosette, subacaulescent. Leaf sheaths brown, membranous, 15–17 mm long, 15–17 mm wide at base. Leaf blades widely spreading, with a broad white median stripe, linear, acuminate, 11–16 cm long, 8–10 mm wide, densely serrulate, not crisped on margins, both surfaces pilosulous, especially beneath. Inflorescence sessile, subglobose, digitately bipinnate from many short spikes, 2.5 cm high, 3.5–4 cm diam. Outer bracts foliaceous, somewhat reduced, sparsely puberulous without, strongly carinate, entire. Floral bracts broadly lanceolate, acute, somewhat longer than the sepals, 15 mm long, 5 mm wide below the middle, entire, glabrous. Sepals lanceolate, acuminate, the outer two carinate, 13 mm long, ca. 3 mm wide, entire, glabrous. Corolla white, 10 mm long. Ovary superior.

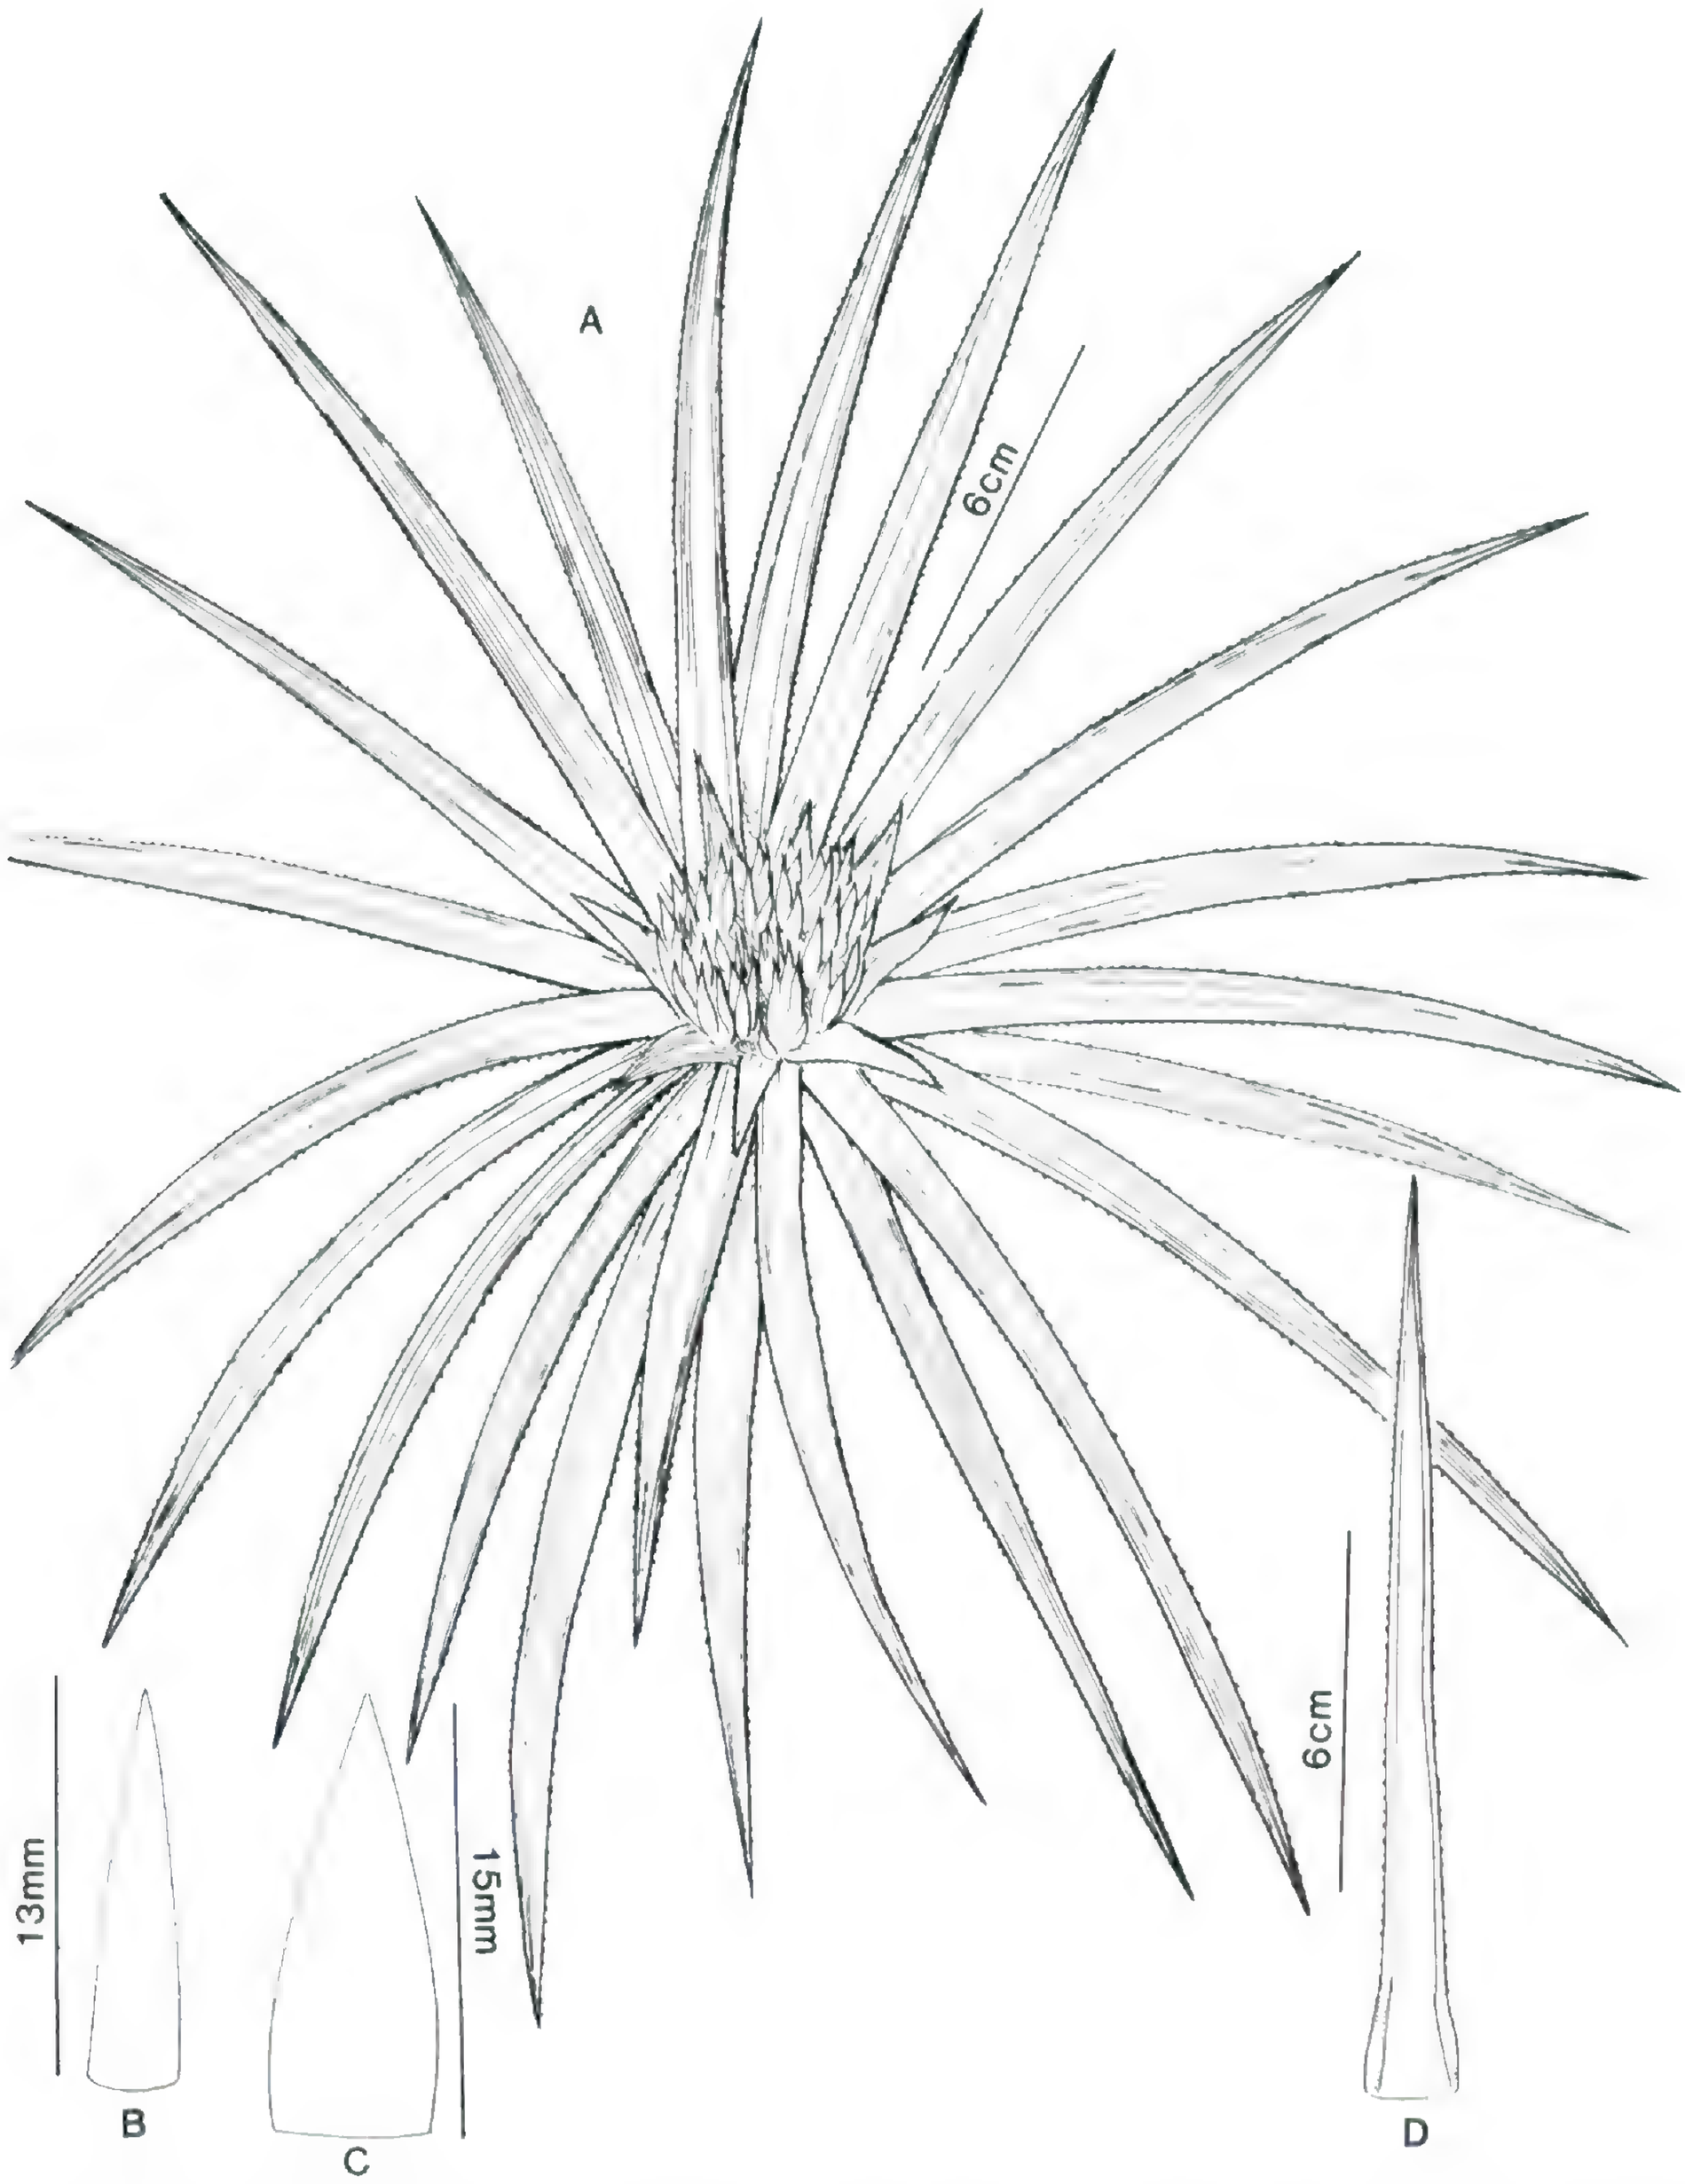

FIGURE 7. *Navia patria.*—A. Habit.—B. Sepal.—C. Floral bract.—D. Leaf. (From *Liesner & Delascio 22041.*)

This species differs from *N. crispa* Lyman B. Smith in having the outer primary bracts pale and only slightly reduced basally, the floral bracts larger, and the leaf margins noncrispate.

Navia platyphylla Lyman B. Smith & Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, steep slope of ravine forest at edge of tepui, 01°26′N, 65°47′W, 1,550 m, 17 Oct. 1987, *R. Liesner & F. Delascio 22062* (holotype, US; isotypes, MO, US). Figure 8.

A *N. diffusa* Lyman B. Smith, cui valde affinis, foliis latioribus spinis longioribus, inflorescentia quadripinnata atra; floribus juvenilibus et alteris reflexis differt.

Terrestrial plant, 2 m tall when fruiting. Sheaths not seen. Leaf blades coriaceous, linear-ligulate, attenuate, 1.3–1.5 m long, 4–4.5 cm wide, strongly spinose in the lower ¼–⅓ with black, broad-based spines 3 mm long, obscurely and sparsely lepidote beneath, mostly glabrous above. Inflorescence laxly 4-pinnate, 2 m tall, longer axes 9–14 cm long, the ultimate axes 3–11 cm long, glabrous, the flowers 3–4 mm apart. Primary bracts broadly triangular, long-attenuate, shorter than the sterile

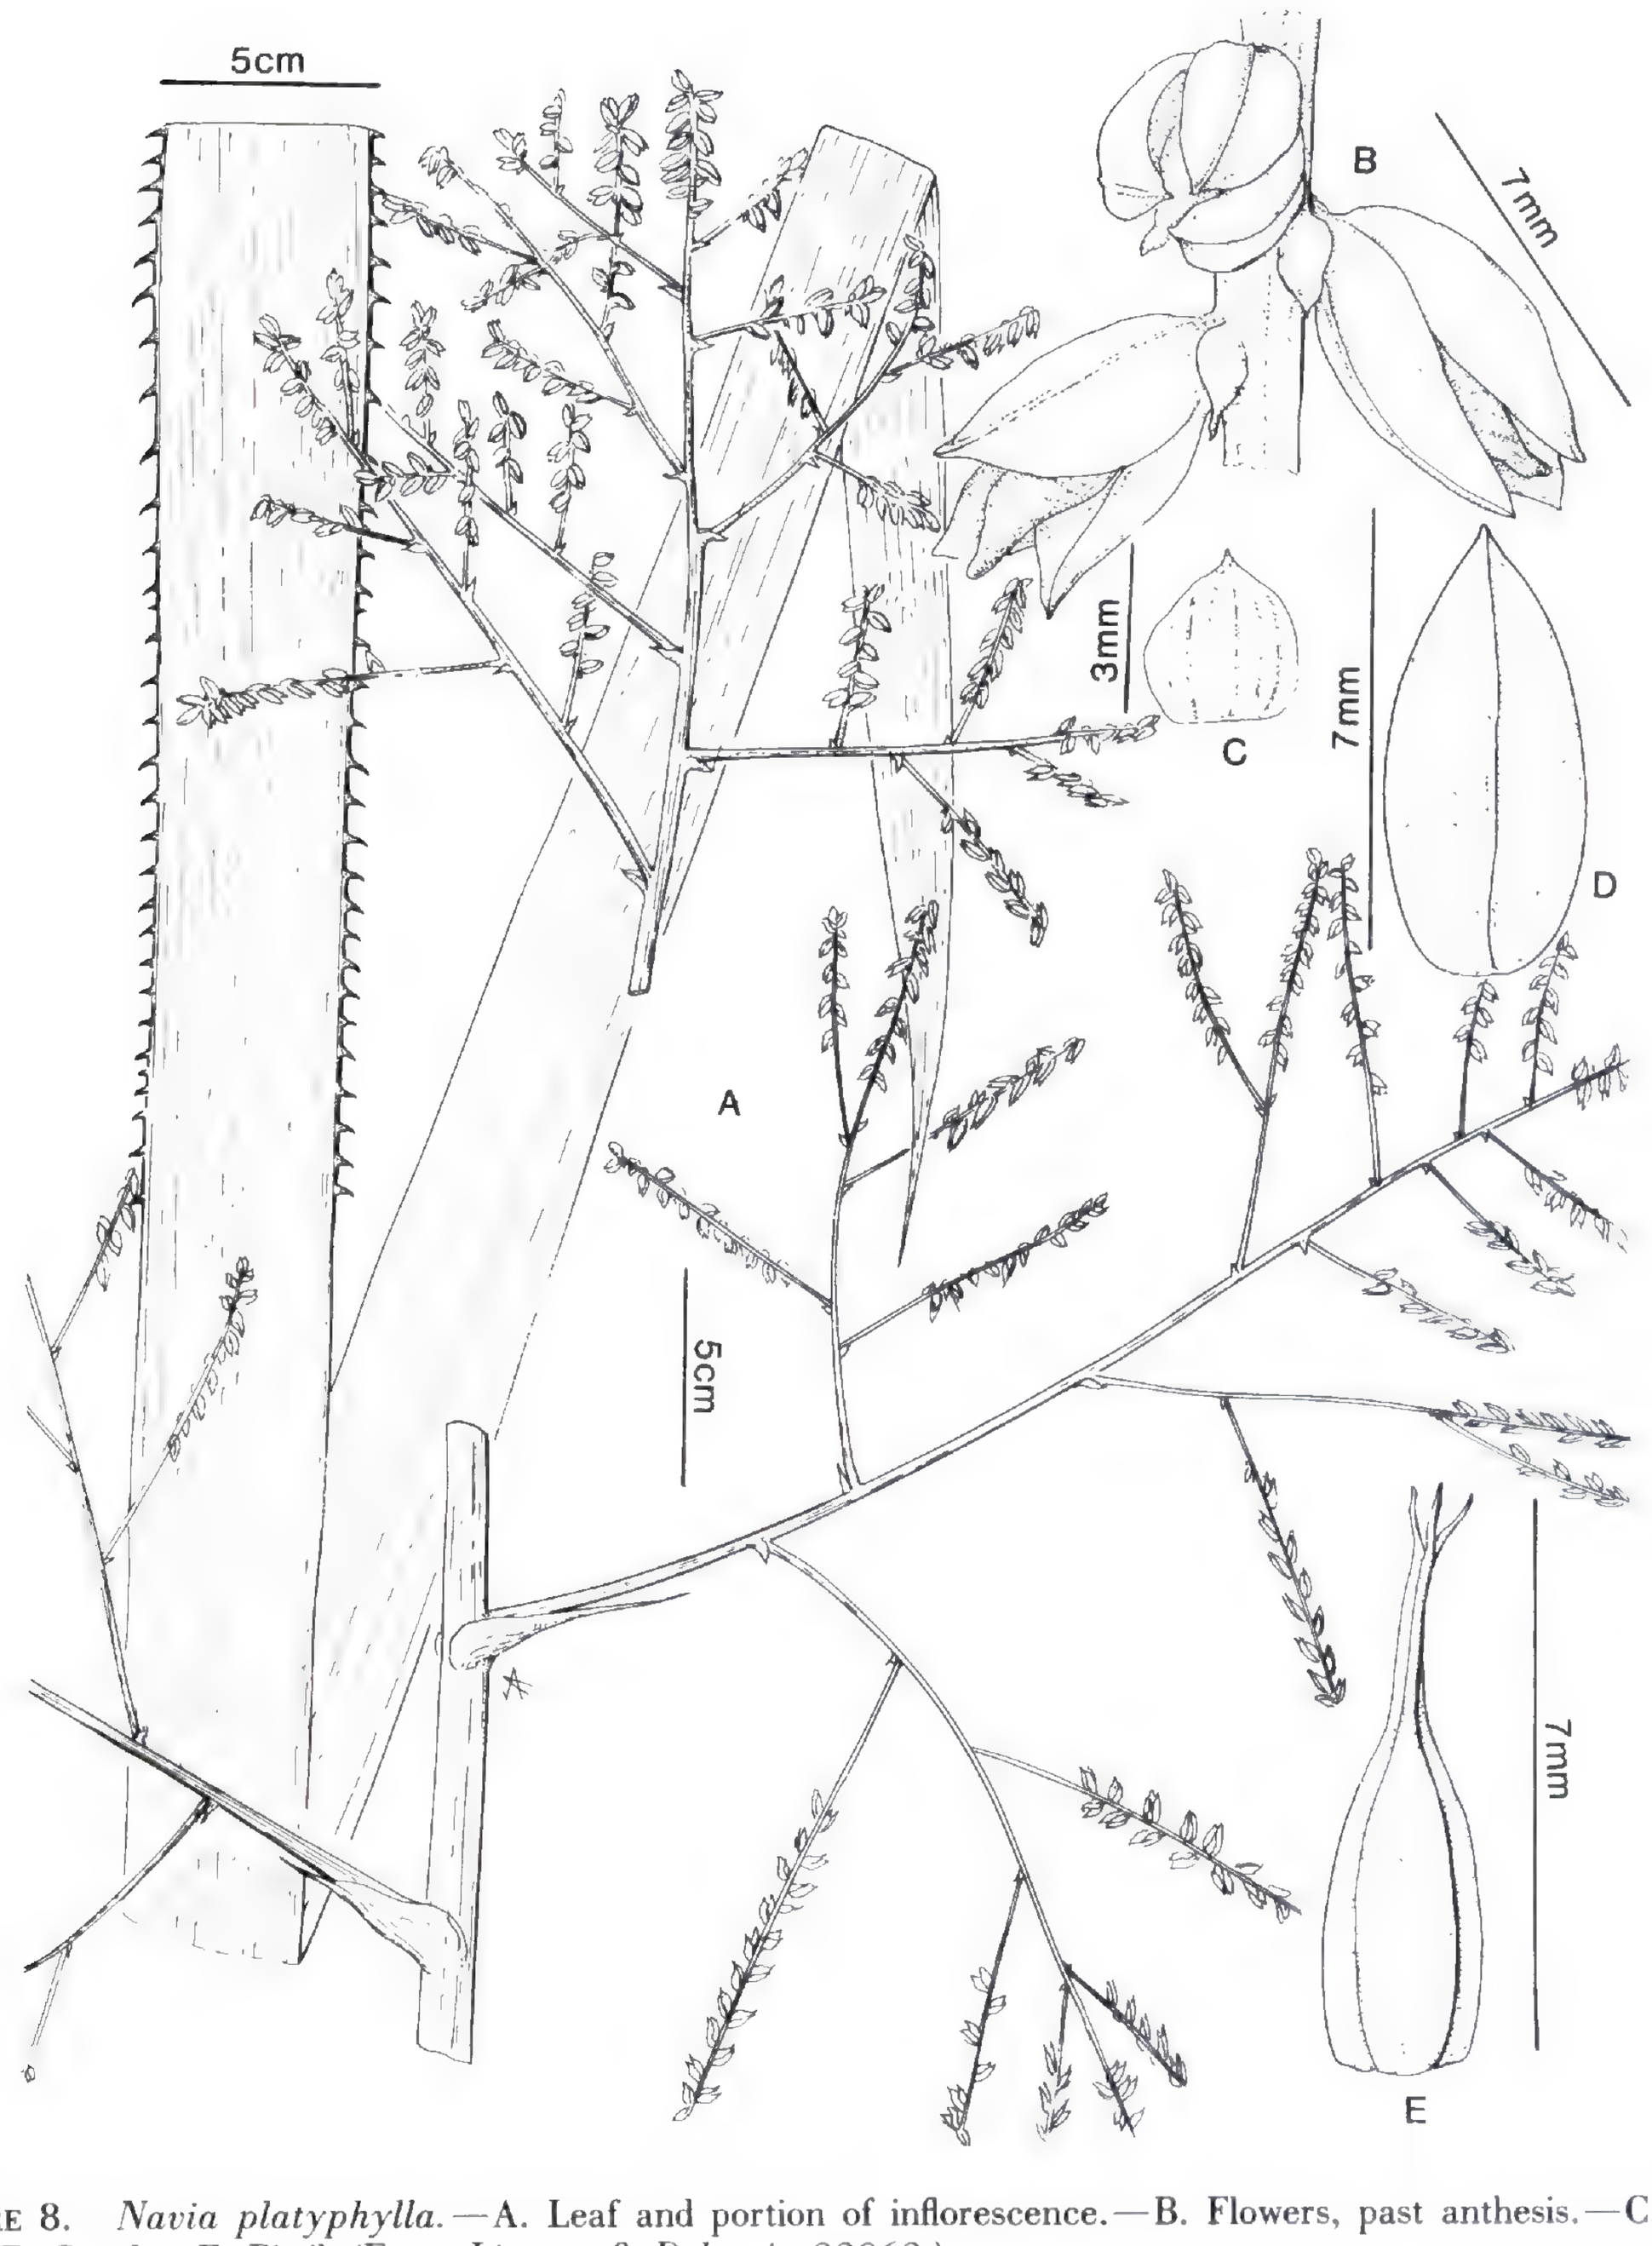

FIGURE 8. *Navia platyphylla.*—A. Leaf and portion of inflorescence.—B. Flowers, past anthesis.—C. Floral bract.—D. Sepal.—E. Pistil. (From *Liesner & Delascio 22062.*)

bases of the main axes, 3.5–4.5 cm long, scarious margined. Bracts subtending the secondary axes broadly ovate, abruptly attenuate, 3–7 mm long. Flowers reflexed. Floral bracts broadly suborbicular-deltoid, subamplexicual, acuminate, 3–5 mm long, about ⅜ length of the sepals. Sepals oblong-ovate or ovate, subobtuse, 4–7 mm long, the posterior strongly carinate. Petals (past anthesis) 9 mm long. Ovary superior, ovoid, 4 mm long.

This species differs from *N. diffusa* by having reflexed flowers (even when young), larger sepals, and much broader leaves with longer, stouter spines. The four-pinnate inflorescences are also characteristic. It is distinguished from *N. hechtioides* Lyman B. Smith by having shorter sepals, the posterior ones nonalate. From *N. brocchinioides* Lyman B. Smith, it is differentiated by the non-digitate, solitary, shorter spikes.

Navia terramarae Lyman B. Smith & Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Araca-

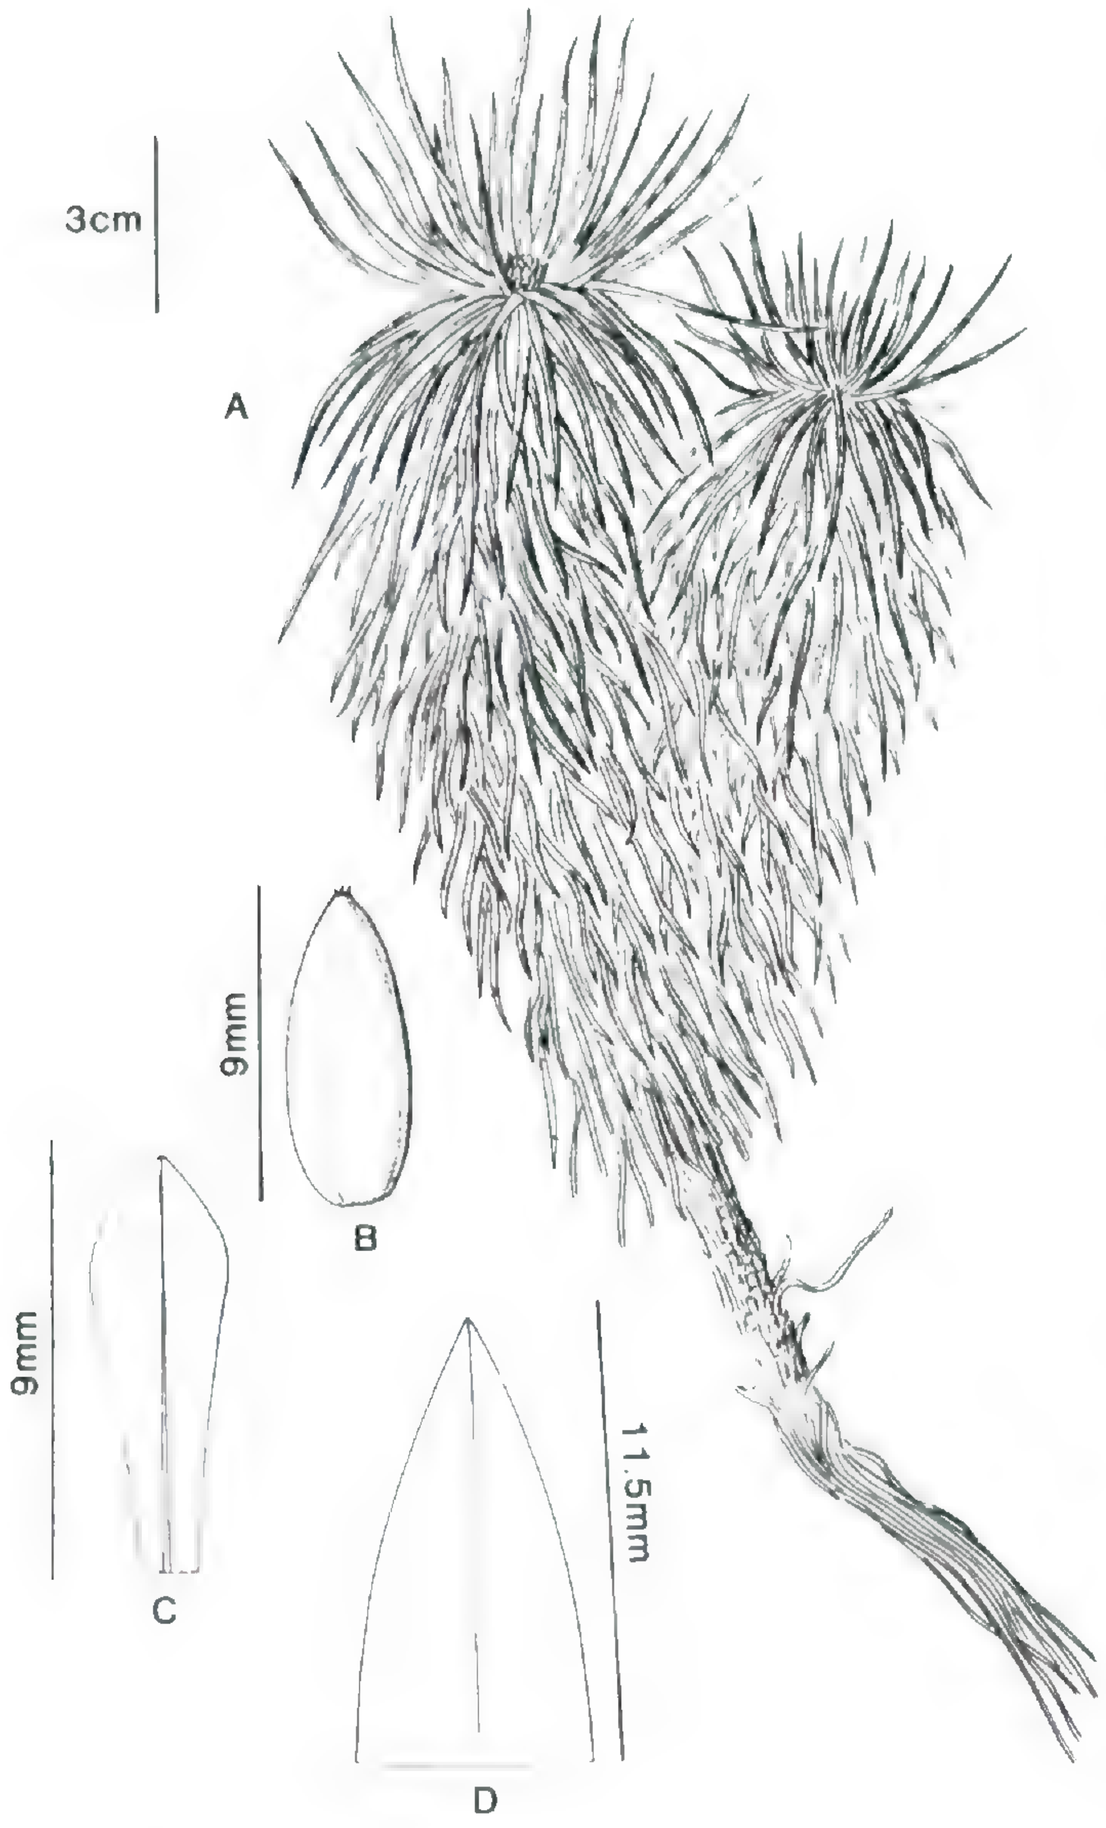

FIGURE 9. *Navia terramarae*.—A. Habit.—B. Fruit.—C. Sepal.—D. Floral bract. (From *Liesner & Delascio 21998, 22599.*)

muni, summit, Popa Camp, savanna with small to large patches of forest and stream, stream bank, 01°26′N, 65°47′W, 1,550 m, 16 Oct. 1987, *R. Liesner & F. Delascio 21998* (holotype, US; isotypes, MO, VEN). Figure 9.

A. *N. liesneri* Lyman B. Smith, Steyerm., & H. Robinson, cui valde affinis, foliorum laminis interioribus ad basin versus albis et a *N. delascionis* Lyman B. Smith, Steyerm. & H. Robinson, item valde affinis, foliorum laminis obscure serrulatis laxe minuteque obscure serrulatis, et ab ambabus caulibus elongatis, ramosis subterraneis, foliis omnino glabris differt.

Caulescent plant with elongated, simple or dichotomously branched stems 10–20 cm long, 0.7–1.5 cm wide. Leaf sheaths brown, membranous, 5–6 mm wide, striate. Leaves crowded in a dense rosette, the older ones strongly reflexed, the interior leaves white basally; leaf blades narrowly linear-triangular, 4.5–6 cm long, 1.5–2 mm wide, glabrous, terminating in a slender apiculum, laxly and minutely spinulose, the spinules ascending, 0.2–0.25 mm long, 1–1.5 mm apart. Inflorescence simple, sessile, glomerate. Outer bracts linear, 1.7–2.5 cm long, minutely serrulate. Floral bract uniformly membranous, ca. 6-striate, broadly oblong-lanceolate, acute, 10–12 mm long, 5.5 mm wide at base. Sepals free, linear-oblanceolate, obtusely acute, 8.5–9 mm long, 1–2 mm wide. Ovary superior. Capsule lance-oblong, slightly narrowed at summit, 9 mm long, 3 mm wide at middle.

This species is closely related to the recently described *Navia liesneri* and *N. delascionis*. The interior leaves are white at the base as in *N. delascionis*, but the more conspicuous teeth resemble those of *N. liesneri*. The leaf blades are narrower than in either *N. liesneri* or *N. delascionis*. The lower margins of the leaf blades are shortly white ciliate in *N. delascionis* and conspicuously floccose-ciliate, whereas in *N. terramarae* the leaf blades are completely glabrous.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, semi-open forest, 01°32′N, 65°49′W, 1,400 m, 28 Oct. 1987, *R. Liesner & G. Carnevali 22599* (MO, US, VEN).

The new species is named for the Terramar Foundation of Venezuela in recognition of the invaluable assistance provided on the expedition to Cerro Aracamuni.

BURMANNIACEAE—contributed by Paul J. M. & H. Maas

Studying the material available of Burmanniaceae for Steyermark's *Flora of the Venezuelan Guayana*, we came across an undescribed species of the saprophytic genus *Hexapterella*. We name it after Julian Steyermark to honor his lifelong dedication to the Venezuelan flora.

Hexapterella steyermarkii P. Maas & H. Maas, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, 01°32′N, 65°49′W, 1,400 m, 29 Oct. 1987 (fl, fr), *R. Liesner & G. Carnevali 22622* (holotype, MO; isotype, U). Figure 10.

Herba saprophytica. Flores hypocrateriformes sex-costati. Perianthium ad maturitatem fructus persistens. Tepala exterioria integra. Tepala interioria tepalibus exterioribus mensura formaque dissimilia. Antherae sessiles tubum floralem non excedentes.

Saprophytic herbs 12–21 cm high. Rhizomes unknown. Stems lavender, unbranched, or sometimes branched at the base of the plant, upper part of stem and inflorescence papillate (papillae ca. 0.02 mm long). Leaves narrowly triangular to tri-

FIGURE 10. *Hexapterella steyermarkii.*—A, B. Habit. C. Old flower with dehiscing capsule.—D. Flower.—E. Leaf.—F. Inner side of flower showing outer and inner tepals, and stamens.—G. Detail of stamen.—H. Seed. (B, from *Maguire et al. 42251*; G, from *Steyermark 105202*; A, C, D, E, F, and H, from *Liesner & Carnevali 22622.*)

angular-ovate, 2–4 mm long, 0.8–2 mm wide, base auriculate, apex acuminate. Inflorescence a bifurcate or single cyme, cincinni 2–6-flowered, 8 25 mm long, flowers 1.8–11 mm apart, or plant having a solitary, terminal flower. Bracts narrowly triangular to triangular-ovate, 1.8–3.5 mm long, 0.6–1.9 mm wide, base often auriculate, apex acuminate. Pedicels 2–4(–5.5) mm long. Flowers pale purple to lavender, or white with purple to lavender lobes, (4.5–)6.5–9.5(–11) mm long. Tepals per-

sistent, papillate on both sides. Outer tepals 3, narrowly triangular(–ovate), 3.0–4.3 mm long, 0.8–1.4 mm wide, margins involute. Inner tepals 3, obcordate to spathulate, 0.6–1.3 mm long, 0.5–0.8 mm wide. Floral tube 2.5–4.9 mm long, 0.8–1.5 mm diam., 6-ribbed. Thecae sessile. Style 3.5–4.6 mm long, branches 0.6–0.9 mm long. Ovary (transversely) obovoid-ellipsoid, 1.2–2.7 mm long, 1–2.5 mm diam., upper part 1-locular, basal part 3-locular. Capsule globose to transversely broadly ellipsoid, 1.5–3.2 mm long, 2–3.5 mm diam., crowned by the persistent perianth, dehiscing by transverse slits and irregularly withering of the wall between the ribs. Seeds irregularly globose to ovoid, 0.3–0.5 × 0.2–0.3 mm.

Distribution. Known only from the Venezuelan Guayana (Territorio Federal Amazonas and Estado Bolívar); (470–)1,100–1,800 m; often along rivers or on dry rock ledges.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Cerro de la Neblina, Río Yatúa, slopes of Cañon Grande below Cumbre Camp, 1,100–1,800 m, 26 Nov. 1957 (fl, fr), *B. Maguire et al. 42251* (NY); Cumbre del Cerro Autana, 1,230–1,270 m, 21–22 Sep. 1971 (fl, fr), *J. Steyermark 105202* (U, VEN). BOLÍVAR: Chimantá Massif, along Río Tirica (Río Apapurén) just above Techiné-Merú, 410 m, 16 Jan. 1955, *J. Steyermark & J. Wurdack 113* (VEN).

Hexapterella steyermarkii is only the second species described in this genus. The other species, *H. gentianoides* Urban, is a fairly common saprophyte in Guyana and Surinam, and has been collected once in Venezuela—at Cerro de la Neblina, between 1,100 and 1,800 m. *Hexapterella steyermarkii* is known from three collections in Territorio Federal Amazonas (Cerros Aracamuni, Neblina, and Autana) and one from Estado Bolívar (Chimantá Massif).

The two species of *Hexapterella* can be distinguished by the following key:

1a. Anthers on long filaments slightly exceeding the floral tube; upper part of perianth caducous; inner tepals narrowly ovate-triangular ..... *H. gentianoides*

1b. Anthers sessile, not exceeding the floral tube; perianth persistent on fruit; inner tepals obcordate ..... *H. steyermarkii*

ERIOCAULACEAE—contributed by Nancy Hensold

Paepalanthus sulcatus Hensold, nom. et stat. nov. *Paepalanthus stegolepoides* var. *acutalis* Moldenke, Phytologia 15: 463. 1968.

Selected specimens examined. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, 01°26′N, 65°47′W, 1,550 m, 15 Oct. 1987, *R. Liesner & F. Delascio 21940* (MO, VEN).

EUPHORBIACEAE—contributed by Grady Webster

Senefeldera yutajensis (Jabl.) Webster, comb. nov. *Sapium yutajense* Jabl., Mem. New York Bot. Gard. 17: 184. 1967, fig. 24. TYPE: Venezuela. Territorio Federal Amazonas: Caño Yutajé, *B. Maguire & C. Maguire 35261* (holotype, NY).

Jablonski noted that the leaf venation and inflorescence of this species suggested *Senefeldera*, but he placed it in *Sapium* because of the staminate flower with a two-lobed calyx and two connate stamens. However, the branched inflorescence, caducous stipules, and especially the non-arillate seeds of the type collection are quite incompatible with *Sapium*. The small stamen number is shared with *Senefelderopsis*, but that genus has unbranched inflorescences and leaves with the veinlets not prominulous. Surprisingly, there is a resemblance to *Mabea*, especially to *Mabea pohliana* (Benth.) Muell. Arg. in sect. *Apodae* Pax & Hoffman (Pflanzenr. 147. V: 39. 1912). That species of *Mabea* has a branched inflorescence, an androecium of only two or three stamens, and an indumentum of dendritic hairs. Yet *Mabea pohliana* differs by having serrulate, short-petiolate leaves without prominulous venation, discrete staminate sepals and stamens, pedicellate pistillate flowers, and an elongated stylar column. In its subsessile pistillate flowers, elongated stylar column, and entire leaves with prominulous venation, *Senefeldera yutajensis* agrees with other species of *Senefeldera*, and this seems the best generic placement despite the indumentum of dendritic hairs. Along with *Senefeldera triandra* Pax & Hoffman (Pflanzenr. 147. XIV: 55. 1919) and possibly *Mabea paraguensis* Muell. Arg. (Fl. Brasil 11(2): 527. 1874), *Senefeldera yutajensis* may represent a phyletic branch intermediate between the genera *Senefeldera* and *Mabea*.

Additional specimens examined. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, 01°32′N, 65°49′W, 1,400 m, 29 Oct. 1987, *R. Liesner & G. Carnevali 22625* (DAV, MO, VEN).

GENTIANACEAE—contributed by Julian Steyermark

Symbolanthus aracamuniensis Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, savanna, 01°26′N, 65°47′W, 1,550 m, 17 Oct. 1987, *R. Liesner*

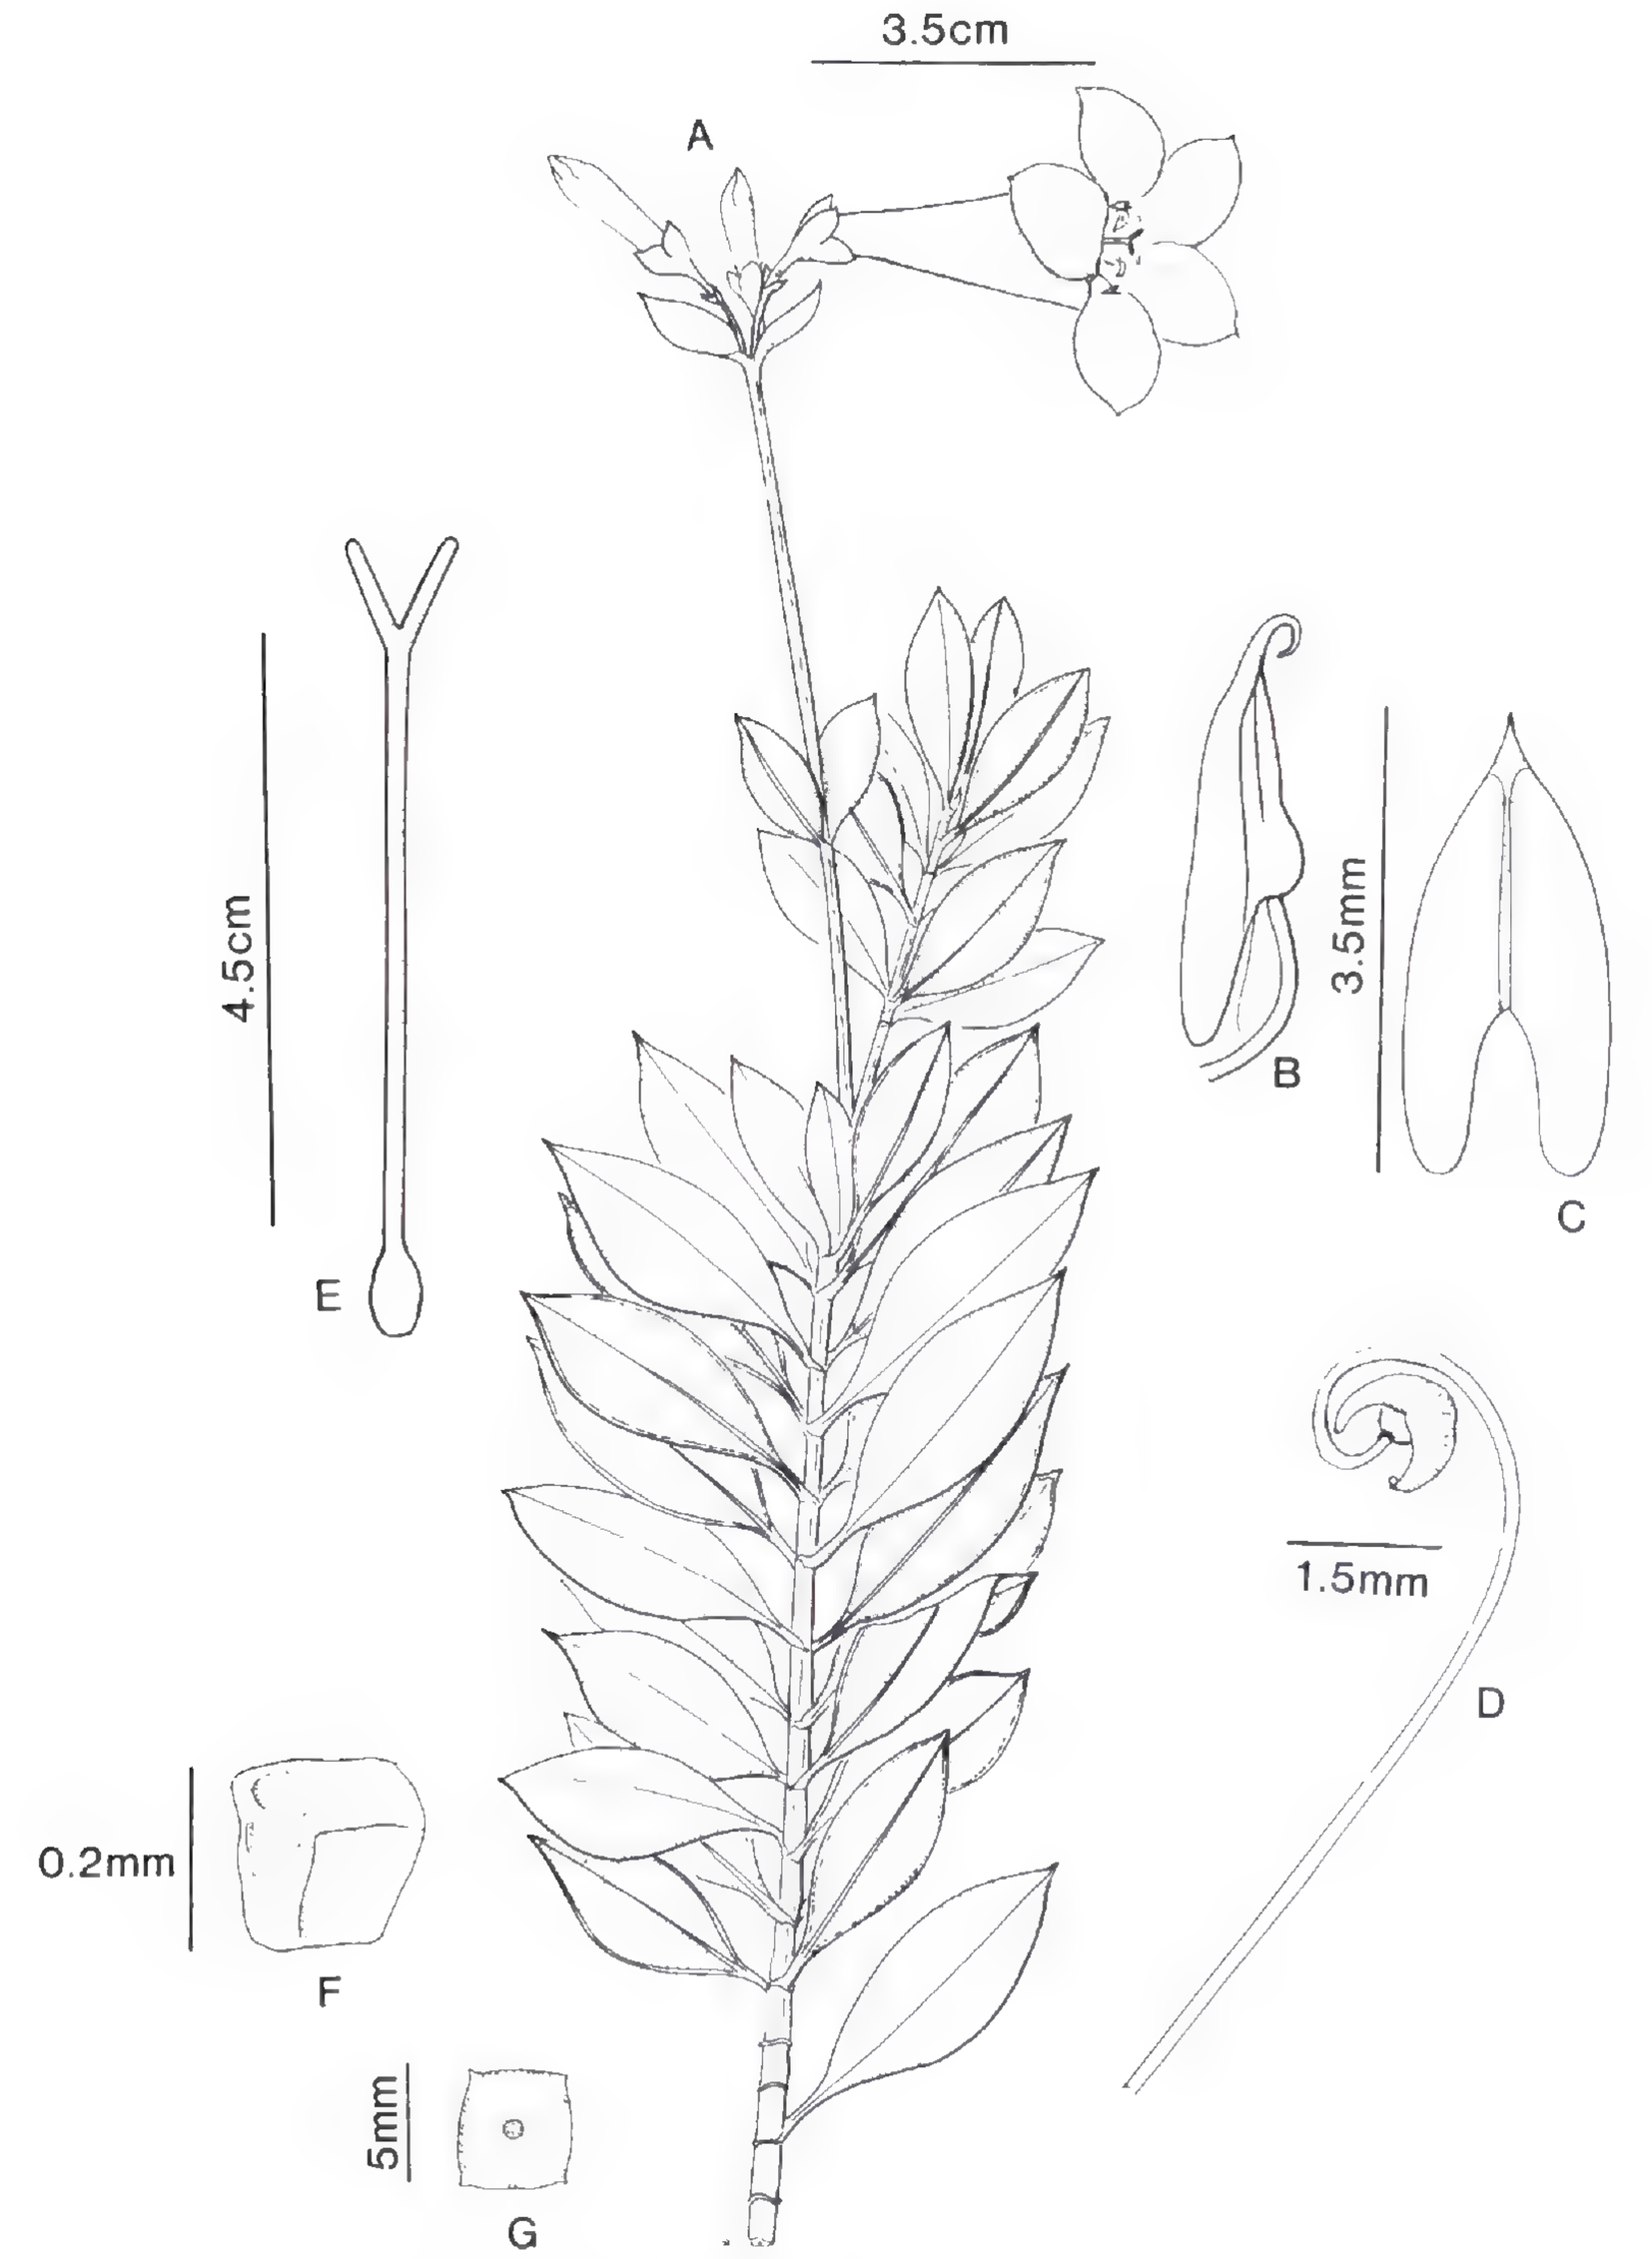

FIGURE 11. *Symbolanthus aracamuniensis.* —A. Habit of branch.—B, C. Anther.—D. Stamen.—E. Pistil. —F. Seed. —G. Cross section of stem. (From *Liesner & Delascio 22079.*)

& F. Delascio 22079 (holotype, MO; isotype, VEN). Figure 11.

A *S. huachamacarensis* et *S. yaviensis* calyce valde reducto, 7 8 mm longo, lobis 5–6 mm longis differt.

Glabrous herb, 0.3–0.8 m tall. Stem 4-angled, 3–3.5 mm diam. Leaves short-petiolate, blades lance- to oblong-elliptic, the apex acute, the decurrent base acute to cuneate, silvery abaxially, the larger lower and middle blades 4–6.5 cm long, 1.5–2.2 cm wide, faintly plinerved above, obsoletely nerved below; petiole 2–7 mm long. Inflorescence terminal, cymosely 3–4-flowered; pedicel slender, 0.5–2 cm long. Calyx 7–8 mm long, 8–9 mm wide, 5-lobed; lobes ovate, obtuse, nearly divided to the base, 5 6 mm long, 4 mm wide, scarious-margined. Corolla lavender-pink, pink, or whitish, infundibuliform, 5–5.5 cm long; tube 3–3.8 cm long, 3–3.5 mm wide at base, 2–3 cm wide at summit; lobes 5, broadly ovate, 2.2–2.5 cm long, 2–2.2 cm wide, broadly curved above to an obtuse mucronulate apex. Stamens 5, subequal, as high as or higher than the orifice of the corolla. Filaments coiling, attached to corolla tube 5 mm above its base, 4 cm long; anthers suboblong, dorsifixed, lance-oblong, sagittate at base, narrowed to a revolute aristate tip, 3.5–5 mm long, 1.5 mm wide, the sagittate lobes 1–1.5 mm long; thecae with a dorsal basal enlargement. Capsule oblong, 13 mm long, 6 mm wide. Seeds quadrangular,

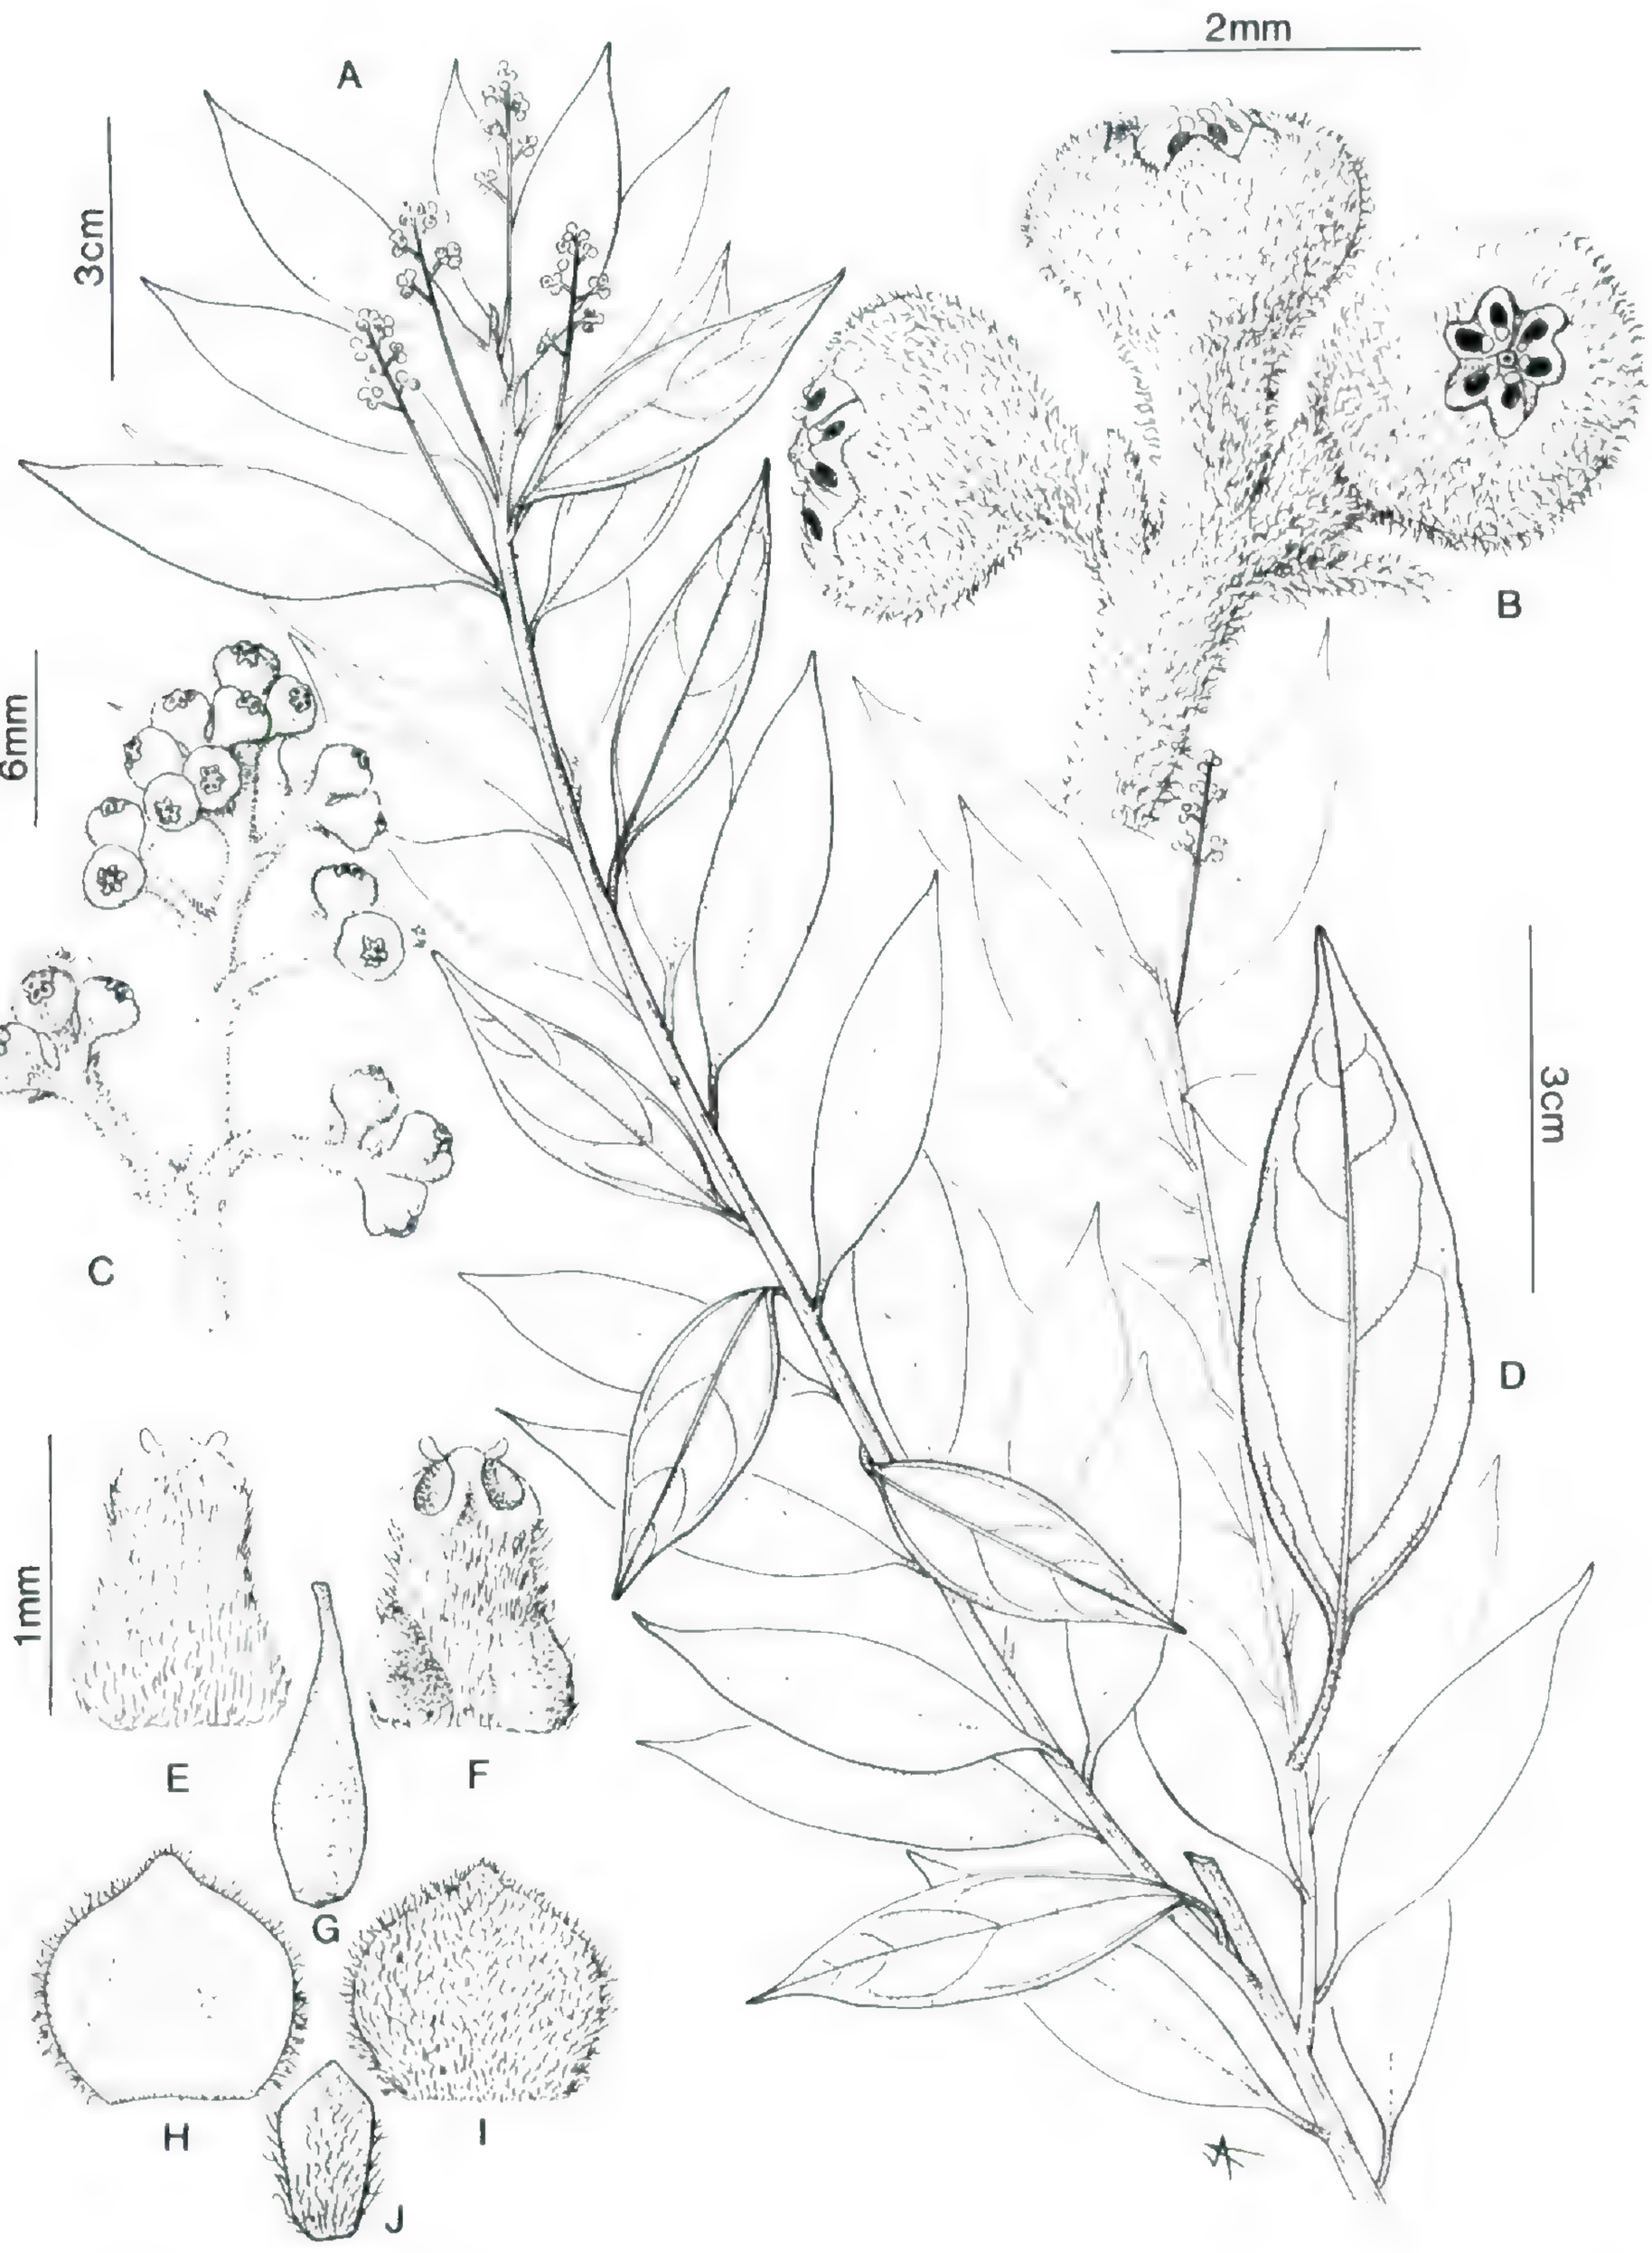

FIGURE 12. *Licaria trinervis*.—A. Habit of branch.—B. Flowers.—C. Part of inflorescence.—D. Leaf.—E, F. Ventral and dorsal views of stamen.—G. Ovary.—H, I. Ventral and dorsal views of tepal.—J. Staminode. (From *Liesner & Delascio 22161*.)

broader than long, 0.2 mm long, 0.3 mm wide, depressed at the summit, the surface plane with a microscopic cellular appearance.

This species differs from *S. yaviensis* Steyerm. and *S. huachamarensis* Steyerm. in its much shorter calyx. Other distinctive characters of the new species are the anthers with revolute, aristate tips and a dorsal enlargement at the junction of the anther with the filament.

LAURACEAE—contributed by Henk van der Werff

Licaria trinervis van der Werff, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, summit of Cerro Aracamuni, 01°26′N, 65°47′W, 1,550 m, 19 Oct. 1987, *R. Liesner & F. Delascio 22161* (holotype, MO; isotypes, HBG, NY, VEN). Figure 12.

Frutex vel arbor parva. Ramuli teretes, juvenales fusco-tomentosi, velustiores glabri. Folia alterna, 4–10 × 1.5–3 cm, anguste elliptica, fortiter chartacea, basi apiceque acuta, super glabra (juvenalissima sparse tomentosa), subtus fusco-tomentosa (vetera glabrescentia). Nervi utroque costae latere 4–5, marginem versus arcuati et connati;

super immersi, subtus elevati, precipue costa et nervi basales. Petioli 0.5–1 cm, fusco-tomentosi, glabrescentes. Inflorescentiae axillares, fusco-tomentosae, paniculatae, foliis breviores, 2–3 cm longae. Pedicelli ad 1 mm longi. Flores fusco-tomentosi, depresse globosi, ca. 1.5 mm longi, ca. 2.2 mm lati; stamina fere tepalis obtecti, solum apicibus expositis. Tepala 6, aequalia, fusco-tomentosa, incurvata, ca. 1 mm longa et 1.2 mm lata. Stamina 3, ca. 1 mm longa, 2-locellata; filamentis liberis, pubescentibus, basi 2 glandulis praeditis; locellis parvis, fere apicalibus. Staminodia 6, 0.5–0.6 mm longa, basibus pubescentia. Ovarium glabrum, ellipsoideum, ca. 0.6 mm longum; stylo gracili, ca. 0.6 mm longo. Fructus ignotus.

Shrubs or small trees, to 5 m tall. Twigs terete, rather slender, brown tomentose when young, glabrescent with age. Leaves alternate, 4–10 × 1.5–3 cm, narrowly elliptic, evenly distributed along the twigs, base acute, apex acuminate, firmly chartaceous, upper surface glabrous or loosely tomentose along the midrib when very young, lower surface brown tomentose when young, tomentum wearing off with age and the oldest leaves occasionally glabrous; lateral veins 4–5 pairs, the basal pair much more strongly developed than the others, all laterals arching upwards and becoming loop-connected; veins immersed above, raised below (especially the midvein and the basal laterals). Petioles 0.5–1 cm long, flattened above, brown tomentose when young, glabrescent with age. Inflorescence in axils of leaves or deciduous bracts, brown tomentose, paniculate, shorter than subtending leaves, 2–3 cm long. Pedicels to 1 mm long, brown tomentose. Flowers brown tomentose, depressed-globose, 1.5 mm long, ca. 2.2 mm wide, the stamens nearly enclosed by the tepals with only their tips exposed. Tepals 6, equal, incurved, ca. 1 mm long, 1.2 mm wide, brown tomentose. Stamens 3, ca. 1 mm long; the filaments free, with 2 glands near the base, pubescent, about as wide as the anthers; anther cells small, nearly apical, opening towards the tip of the anther. Staminodia 6, representing the two outer whorls, ca. 0.5–0.6 mm long, their bases pubescent. Ovary glabrous, ellipsoid, ca. 0.6 mm long; style slender, ca. 0.6 mm long. Fruit unknown.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, summit of Cerro Aracamuni, Proa Camp, 01°32′N, 65°49′W, 1,400 m, 25 Oct. 1987, *R. Liesner & G. Carnevali 22451* (MO, VEN), 2 Nov. 1987, *R. Liesner & G. Carnevali 22714* (MO, VEN).

Licaria trinervis belongs to subg. *Licaria*, as defined by Kurz (1983). It does not seem to have close relatives within this subgenus; among its striking characters are the brown tomentose pubescence on the young parts, depressed-globose flower shape, strongly developed basal pair of lateral veins on the leaves. Another distinction is that no other *Licaria* species in the Venezuelan Guayana is known from the tepui summits, although *L. macrophylla* (A.C. Smith) Kostermans is known from slopes of Cerro Huachamacari at 600 m, *L. tomentosa* van der Werff occurs on the slopes of the Chimantá Massif.

Persea perseiphylla (Allen) van der Werff, comb. nov. *Ocotea perseiphylla* Allen, Mem. New York Bot. Gard. 10: 109. 1964.

This species was known to Allen only from the holotype (*Schultes & Lopez 10103*, US), a specimen in young bud. Characters necessary for correct generic placement were not discernible at this young stage, and Allen mistakenly placed the species in *Ocotea*. Fruiting specimens show clearly that this species belongs in *Persea*. Inspection of the holotype also showed that the tepals of the buds are unequal, with the outer three shorter than the inner ones, a character found in most neotropical *Persea* species but never in *Ocotea*. Hence *Ocotea perseiphylla* is transferred to *Persea*. Because open flowers have not yet been collected, *P. perseiphylla* cannot be placed in any of the sections of subg. *Eriodaphne* Nees; the general resemblance to *P. maguirei* L. Kopp and *P. croatii* van der Werff suggests that it belongs in sect. *Aurataea* Kopp. It has nine four-celled stamens and therefore does not belong to sect. *Hexanthera* Kopp.

Additional specimens examined. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, 01°26′N, 65°47′W, 1,550 m, 18 Oct. 1987 (fr), *R. Liesner & F. Delascio 22099* (MO); 19 Oct. 1987 (fr), *R. Liesner & F. Delascio 22169* (MO); vertiente sur de la Sierra de Unturán, cabeceras del Río Mavaca, 01°32′N, 65°11′W, 550–650 m, 26 Feb. 1981 (fr), *F. Guánchez 809* (MO, TFAV).

MELASTOMATACEAE—contributed by John J. Wurdack

Tococa liesneri Wurd., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, savanna with small to large patches of forest, 01°32′N, 65°49′W, 1,400 m, 1 Nov. 1987, *R. Liesner & G. Carnevali 22700* (holotype, MO 3502486; isotype, US).

T. obovata Gleason affinis, foliorum laminis (3-nervatis) et petiolis minoribus, calycis dentibus exterioribus vix eminentibus, petalis minoribus differt.

Shrub 0.4–0.5 m tall, the terete branchlets moderately puberulous with dendritic hairs ca. 0.2 mm long and sparsely glandular-setose with smooth hairs 1–2 mm long. Petioles 0.5–1 mm long; blade 1.5–

2.5 × 0.8–1.4 cm, ovate-oblong, apex rounded-acute, base cordulate, subcoriaceous and entire, ciliate with loosely appressed and in part gland-tipped hairs, above sparsely loose-strigose with smooth hairs 1.5–2.5 mm long, below sparsely loose-strigulose with gland-tipped hairs on the primary veins and very sparsely puberulous with short dendritic hairs but esetulose on the surface, 3-nerved (excluding the tenuous incomplete inframarginals), with obscure lax venule reticulation. Flowers 5-merous, solitary or ternate at branchlet ends, pedicels 2–7 mm long and (as the hypanthium) moderately dendritic-puberulous and glandular-setulose, the persistent bracteoles 2–2.5 × 0.7 mm and usually inserted ca. 0.5 mm below the ca. 5–5.4-mm-long hypanthium; calyx tube ca. 0.6 mm long, the oblong interior lobes ca. 3–3.5 × 2 mm, the glandular-setulose external teeth not or barely projecting (to 0.2 mm); torus glabrous within. Petals 10–11 × 8–9 mm, obovate-oblong with rounded-truncate apex, pink and glabrous. Stamens essentially isomorphic, glabrous; filaments ca. 6.5–7 mm long; anthers ca. 5 × 0.6 × 0.5 mm, oblong-subulate with ventrally inclined pore and with short blunt-basal spur. Stigma not expanded; style ca. 11–12 × 0.3–0.5 mm; ovary 3-celled and ca. 3 mm inferior, the truncate glabrous apical cone 1.4–1.5 mm long.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, savanna, 01°26′N, 65°47′W, 1,550 m, 16 Oct. 1987, *R. Liesner & F. Delascio 22007* (MO, US).

Tococa obovata has distinctly five-nerved leaf blades measuring mostly 4–8 × 2–5 cm, petioles 0.3–0.7 cm long, external calyx teeth projecting 1–2 mm, and petals 15–21 × 7–9 mm; its interior calyx lobes are similarly developed, and both species have glabrous petals. In general vegetative aspect, *T. liesneri* resembles the typical subspecies of *T. bolivarensis* Gleason, which has broadly deltoid calyx lobes ca. 0.5 mm long and densely pruinose-granulose petals. The collection *Pires & Marinho 15708* (US, in fruit, from Brazil. Amazonas: alto Río Negro, São Gabriel da Cachoeira) bears a strong resemblance to *T. liesneri* except for completely eglandular vegetative setae.

OCHNACEAE—contributed by Julian Steyermark

Sauvagesia guianensis (Eichl.) Sastre subsp. **aracamuniensis** Steyerm., subsp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, savanna, 01°26′N, 65°47′W, 1,550 m, 17 Oct. 1987, *R. Liesner & F. Delascio 22075* (holotype, MO; isotype, VEN).

A subsp. *guianense* squamulorum laminis suborbicularibus apice late rotundatis, foliorum glandulis marginalibus utroque latere 1–3 adpressis recedit; a subsp. *guaiquinimensis* petalis apice rotundatis, squamulorum lami a subsp. *sipapoensis* atque subspeciebus alus foliorum glandulis marginalibus paucis differt.

Subligneous plant 0.5–1 m tall. Leaves linear-oblanceolate, 9–10 mm long, 1.8–2 mm wide, remotely appressed serrulate with 1–3 appressed glandular teeth on uppermost 1.5–2 mm of margins, obtusely acute at apex with a blunt, glandular protuberance; lateral nerve depressions obliquely ascending. Pedicels 2 mm long, flowers hidden in the upper leaves. Petals pink, obovate, rounded at apex, 6.5 mm long, 3.8–4 mm wide at the middle. Staminodia 9–10 mm long, the lamina suborbicular, 0.3–0.5 × 0.3–0.5 mm, stipitate portion 0.6–0.7 mm long.

This subspecies is distinguished from subsp. *guianense* by having the leaf margins remotely appressed serrulate with 1–3 glandular teeth on each side of the uppermost 1.5–2 mm of the margins, and the leaf apex with a blunt, glandular protuberance. From subsp. *sipapoensis* Steyerm. it differs by the relatively few appressed glandular teeth on each of the uppermost margins and the suborbicular rounded lamina of the staminode. It differs from subsp. *guaiquinimensis* Steyerm., which has a similar suborbicular rounded lamina, in the rounded petals.

ORCHIDACEAE—contributed by Germán Carnevali & Ivón Ramírez

The generic revision of the Spiranthinae by L.A. Garay (1982) formed the basis for a better understanding of the spiranthoid complex. A reevaluation of this group for a treatment of the Orchidaceae from the Venezuelan Guayana has revealed the presence of a very distinctive new species that cannot be assigned to any of the genera delimited in Garay's revision.

Aracamunia liesneri Carnevali & I. Ramírez, gen. et sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, on moss covered streambank in almost closed forest, 01°26′N, 65°47′W, 1,550 m, 16 Oct. 1987, *R. Liesner & F. Delascio 21988* (holotype, VEN; isotype, AMES, MO). Figure 13.

Plantae terrestres, graciles, minutae (vix 4–7 cm altae); radicibus cylindraceis, carnosis, pubescentibus; foliis basalibus vel caulescentibus subpetiolatis, vagina basi appendice liguliformi rigido ascendenti apice irregulariter dilatato pilis minimis breviter pedunculatis instructo; caulibus e rhizomate brevi decumbenti vix erectis; racemo

elongato remote paucibracteato, apice laxe spicato; floribus parvulis. Species singula adhuc nota, venezuelensis. Sepala similia, inter se satis alte connata, nectarium vel tubum amplum formantia, apicibus parallelibus; sepalis extus minute glandulari-papillosis, sepalo postico columnae basi dorsaliter adnato; sepalis lateralibus sepalo dorsali valde similibus, antice valde concavis, sepalo postico partim agglutinata, basi leviter decurrentia. Labellum longe unguiculatum, ungue tubo sepalino omnino adnatum, deinde sagittatum, marginibus in medio utrinque columnae lateribus agglutinatis. Columna erecta, dorsaliter sepalo postico satis alte adnata, apice libera, basi in pedem brevissimum apice ovarii oblique praedita; stigmate transverse elliptico; rostello valido, oblongo, apice truncato, apice structura globulari et papillosa praedito. Anthera ellipsoidea. Pollinia lineari-clavata, viscidio parvulo, rotundo affixa. Ovarium subcilindricum, sessile, haud tortum.

Small terrestrial or muscicolous erect herbs, 4–7 cm high. Roots cylindric, 3–6, fleshy, coarse, pubescent, up to 3 cm long. Stems 5–15 mm long, ca. 3 mm thick, totally enveloped by the leaf sheaths, terete. Leaves glabrous, thinly subfleshy, marcescent, 7–11 per rosette, 4–5 fresh at flowering, sheaths imbricating and invaginating the stem, lamina flat or concave, margins slightly undulate, elliptic or ovate-elliptic, acute or shortly acuminate, 5–9 mm long, 3–4 mm wide, basally contracted into a channeled pseudopetiole 1–1.5 mm long and wide, this merging into the sheath. Sheath ovate to ovate-elliptic, ca. 5 mm long, 4 mm wide when flattened, with 1(2) erect, liguliform structures connected at the center of the sheath base and protruding from it, these 3.8–4.5 mm long, 1–1.2 mm wide, rigid, ± expanded apically where covered by multicellular short-pedunculate, globose hairs ca. 0.05 mm long. Inflorescence a terminal raceme, 35–45 mm long, laxly 3–6-flowered, fertile in the upper ¼, covered (except for the bracts) with sparse, cylindric to subcapitate, unicellular hairs ca. 0.1–0.2 mm long. Peduncle terete, 21–28 mm long, triarticulate, each articulation subtended by one glabrous, lanceolate, long-acuminate bract, this basally enveloping and apically spreading, the lowermost bracts 6.5–7 mm long, 3 mm wide, the apical bracts 5 mm long, 2 mm wide. Rachis 12–17 mm long, straight or slightly fractiflex. Floral bracts 3–7 mm long, 2–2.5 mm wide, identical to the peduncle bracts but somewhat smaller, much longer than the pedicellate ovary. Flowers tubular, not resupinate, white, 7–8 mm long including the ovary, forming an acute angle with the rachis. Ovary subcylindrical, 2–2.2 mm long, 1–1.2 mm thick. Sepals fused in the basal ¾, forming a cylindric, 5–5.5-mm-long tube around the column, petals, and labellum, the free parts concave, triangular-oblong, rounded apically, 2–2.1 mm long, 0.9–1.1 mm wide, minutely glandular-papillose without; dorsal sepal partially adnate to back of column in the basal ⅓ within. Petals membranaceous, connivent with the dorsal sepal along their whole length, uninervate, linear-spathulate, ca. 5 mm long, 0.7 mm wide near apex, 0.1–0.2 mm wide in the attenuated basal half. Labellum connivent with column margins, membranaceous, trinervate, 5.5–6 mm long, ca. 1 mm wide near apex, narrowly oblong in general outline, somewhat dilated in the apical ¼, apex obtuse, thickened and finely papillose-ciliate, base sagittate with 2 retrorse, linear-oblong, apically rounded and thickened lobes 1.3–1.5 mm long, 0.4 mm wide; labellum attached to ovary apex by a relatively long, linear-oblong claw, 0.9–1.2 mm long, 0.4 mm wide, this adnate to the sepaline tube. Column erect, elongate, subcylindric, 4.5 mm long, 0.7–0.8 mm wide at base. Anther ellipsoid, bilocular, obtuse at both extremes, 2 mm long. Rostellum oblong, 1.8 mm long, ca. 1 mm wide, apically truncate and bearing a globular, papillose structure 0.4 mm long and wide. Clinandrium margins narrow, membranaceous, ± erect and slightly enclosing the anther. Stigmatic surface ventral, papillose, transversely elliptic, 0.8 mm wide.

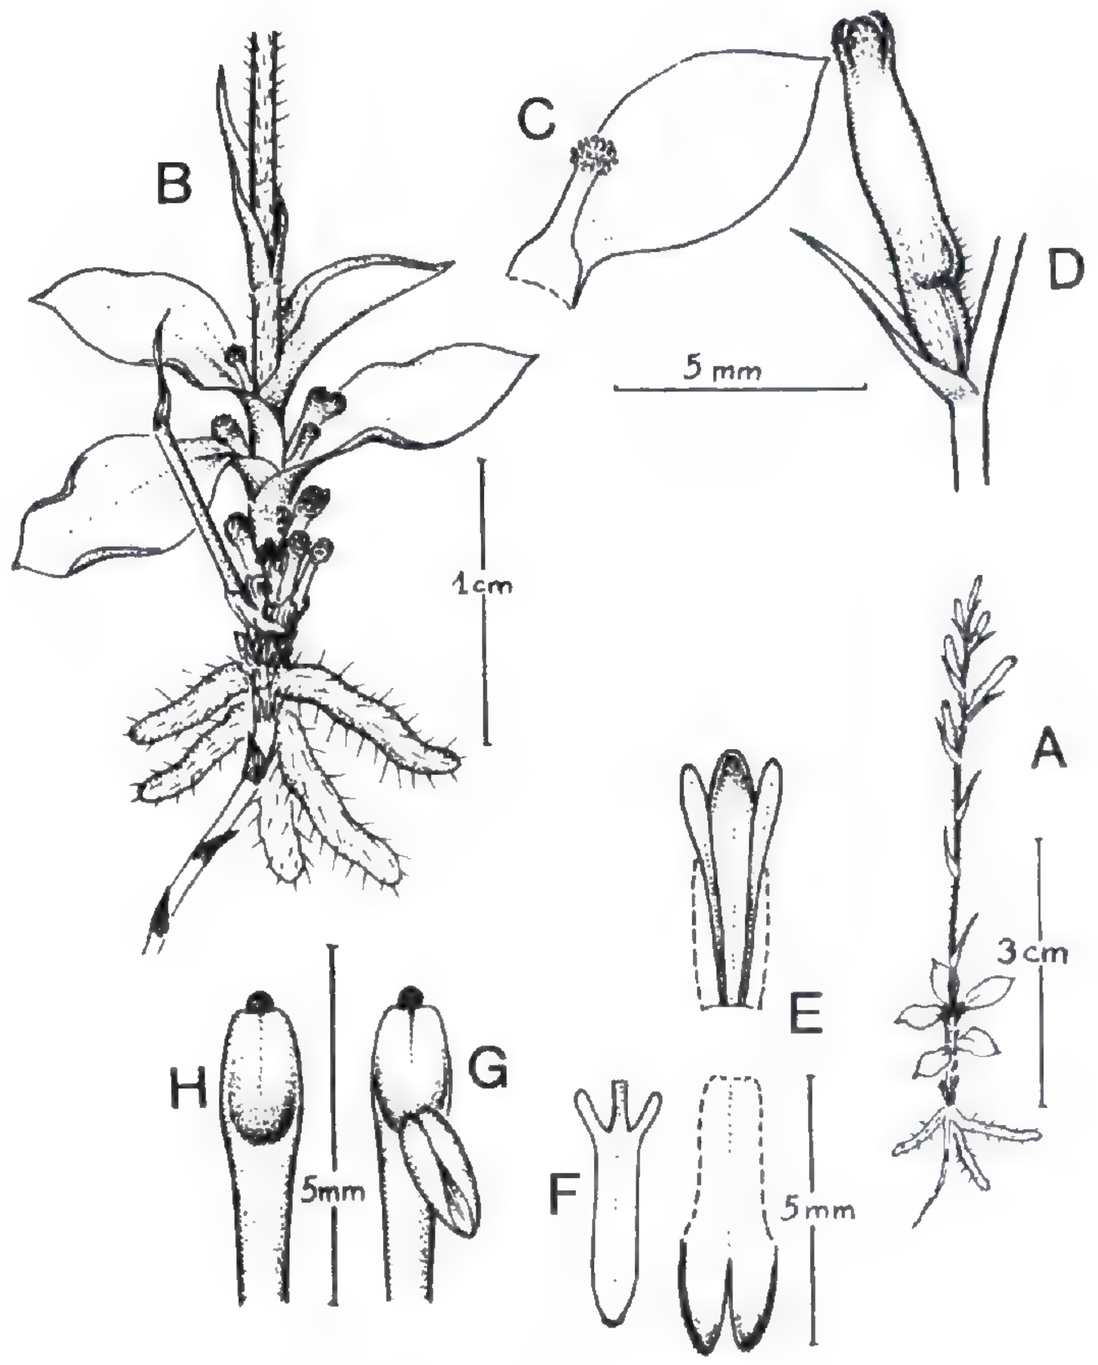

FIGURE 13. *Aracamunia liesneri.*—A. Habit.—B. Detail of plant, showing the ligulelike structures. —C. Leaf with ligulelike structure at leaf sheath.—D. Flower, pedicellate ovary, and floral bract. E. Perianth segments.—F. Labellum.—G. Upper side view of column, with anther retracted. —H. Lower side view of column showing stigmatic surface. (From *Liesner & Delascio 21988.*)

This new genus seems to belong to the *Eury-*

styles Wawra complex, with which it shares the small vegetative habit, nonresupinate flowers, and sepals connate for at least part of their length. However, *Aracamunia* differs from the other genera of the *Eurystyles* complex in its terrestrial habit, eciliate leaves and bracts, presence of ligulelike structures, noncapitate inflorescences, and ecristate sepals connate for about ¾ of their length (vs. up to ½ their length). Within the complex, it seems to be closer to *Eurystyles* as defined by Burns-Balogh et al. (1985), but in *Aracamunia* the stigmas are confluent as in *Pseudoeurystyles* Hoehne.

The most distinctive feature of *Aracamunia* is the presence of the ligular, apparently glandular structures that originate from the bases of the leaf sheaths and persist even after disintegration of the leaf blades and sheaths. These ligular structures are erect, rigid, solitary, or (rarely) in pairs on each leaf sheath. They show traces of vascular axes, with phloem extending farther apically than the xylem, suggesting a glandular function. The apices vary widely in shape: sometimes bifid, lobulate, coarsely dentate, or expanded into a suborbicular blade. The multicellular hairs of the liguliform structures are denser in younger more apical portions, with each of the hair cells containing a large nucleus proportionate to the size of the cells.

The ligular structures have vascular connections with the leaf sheaths and the stem. Further study is required to determine if they are glandular or perhaps have an assimilative function.

Etymology. Generic name for Cerro Aracamuni where the type species was collected, in the Federal Territory of Amazonas in southern Venezuela. The specific epithet honors Ronald Liesner who collected the type material.

PIPERACEAE—contributed by Julian Steyermark

Piper mosaicum Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, savanna with small to large patches of forest and stream, 01°26′N, 65°47′W, 1,550 m, 16 Oct. 1987, *R. Liesner & F. Delascio 21968* (holotype, MO; isotype, VEN). Figure 14.

Frutex 1 metralis; ramis retrorse pubescentibus; foliis elliptico-lanceolatis apice acute acuminatis, basi aequilateraliter subacutis vel acutis, breviter mucronatis 8.5–14 cm longis 2.5–4 cm latis, conspicue reticulatis argenteo-maculatis ubique rugulosis, praeter squamas farinaceas lepidotas glabris, subtus nervis et costa media adpresso-pubescentibus, squamis farinaceis onustis; totis pinnatim venosis, nervis lateralibus utroque latere 5–8; petiolis 2–7 mm longis adpresso-puberulentis, infra medium vaginatis; spicis erectis 17 mm longis 5 mm latis, pedunculis 4.5 mm longis, breviter retrorse puberulis.

Shrub 1 m tall; stems nodose, minutely and retrorsely subappressed-pubescent, 3–4 mm thick. Leaf blades elliptic-lanceolate, acuminate at the minutely mucronate apex, equilaterally acute to subacute at base, drying gray-silvery and blackish, reticulate-rugulose both sides, 8.5–14 cm long, 2.5–4 cm wide, upper surface glabrous except for farinaceous lepidote scales, the darker areas with more minute scales, lower surface paler, covered with a dense farinaceous lepidote layer with pale stellulate trichomes along the midnerve, pinnately nerved throughout to the upper ¼, the lateral nerves 5–8 each side; midnerve and lateral nerves on lower surface appressed-pubescent. Petioles 2–7 mm long, minutely appressed-puberulent, the petiolar sheath vaginate in lower half. Spikes erect, 17 mm long, 5 mm wide, peduncle 4.5 mm long, shortly retrorsely puberulous. Stigmas sessile, spreading over the summit of the fruit. Fruit depressed-truncate at summit, suborbicular, subquadrangular.

This species differs from *Piper gentryi* Steyerm. by having mottled, smaller leaf blades; shorter petioles with sheaths that are longer, winged; retrorsely pubescent stems and peduncles; and fewer lateral nerves. It is distinguished from *P. holtii* Trel. & Yuncker by having shorter peduncles and spikes and smaller, mottled leaf blades that lack the sulcate nerves on upper leaf surface and lack conspicuously elevated nerves of the lower surface.

RAPATEACEAE—contributed by Julian Steyermark

Rapatea aracamuniana Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, slope, Quebrada Camp, area of rapids flowing over laja, river bank in sun, more common in shade, 01°24′N, 65°38′W, 600 m, 20 Oct. 1987, *R. Liesner & F. Delascio 22197* (holotype, MO; isotype, VEN). Figure 15.

Planta herbacea; foliorum laminis supra omnino minute dense papillato-verruculosis, subtus conspicue fusco-glanduliferis ornatis inter punctos minores dispositis; spiculis (sepalis exclusis) 23 25 mm longis; bracteolis infimis 17 18 mm longis; antheris 10 mm longis; filamentis ciliolatis.

Herb. Leaves petiolate, sheaths 11–13 cm long, 6–8 cm wide, conspicuously many-costate, densely papillate; leaf blades ligulate-lanceolate, falcately acuminate at apex, inequilaterally acute at base, 36–66 cm long, 5–7.4 cm wide at the middle, upper surface densely verruculose-papillate, lower

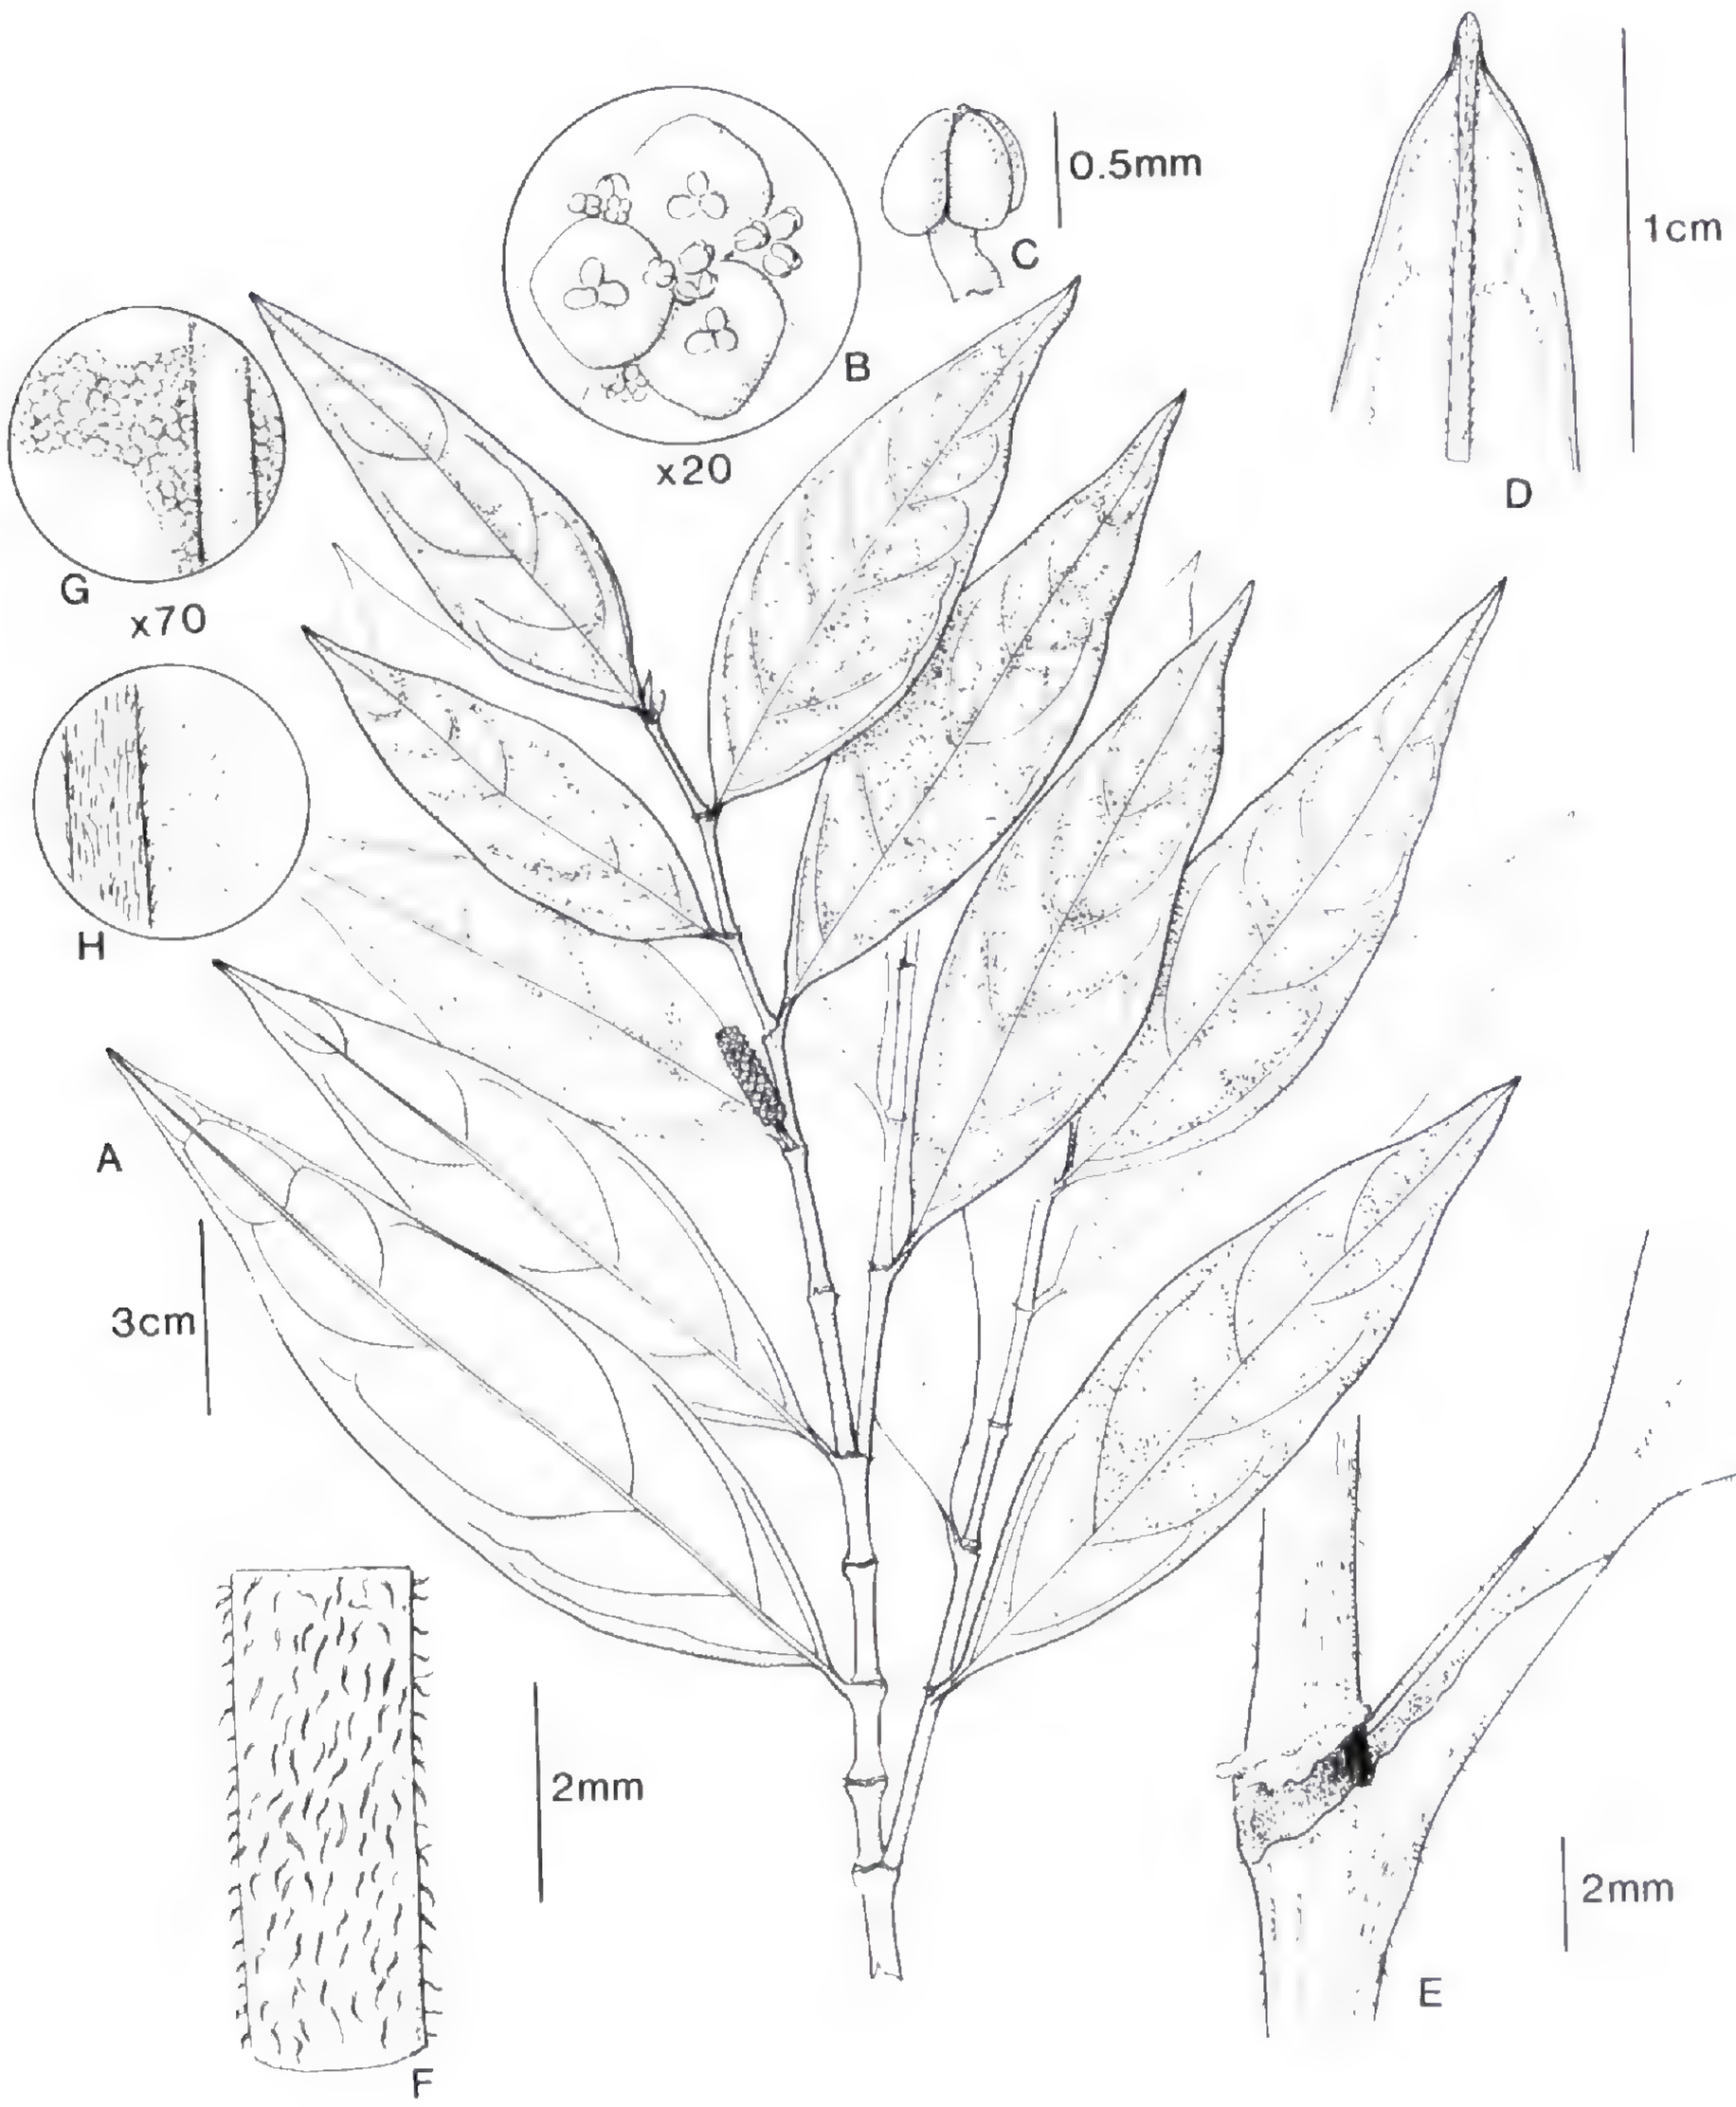

FIGURE 14. *Piper mosaicum.*—A. Habit of branch.—B. Detail of spike.—C. Anther.—D. Leaf tip, lower surface.—E. Detail of stem node.—F. Stem.—G, H. Details of lower leaf surface. (From *Liesner & Delascio 21968.*)

surface with brown glandular punctae regularly distributed between smaller punctate glands, midrib conspicuously impressed on upper surface, elevated on lower surface, bordered by 55–60 finely elevated parallel nerves on each side. Petiole 3–7.5 cm long, 8–9 mm wide. Inflorescence solitary, pedunculate, shallowly hemispherical, 4.5–6.5 cm long, 8–12.5 cm wide, enveloped by 2 broadly deltoid involucral bracts; these cordate at base and acute at apex, 7–12.5 cm long, 9–10 cm wide, minutely brown papillate-verruculose without, minutely pale papillate within. Spikelets numerous, pedicellate; pedicels 10–13 mm long, 1 mm wide, broadened to 1.5 mm wide at summit. Spikelets numerous, (excluding sepals) 23–25 mm long, 5 mm wide, ca. 12-bracteolate. Bracteoles graduate, the lowest 17–18 mm long, 3 mm wide, ¾ length of spikelet, linear-lanceolate, acute, scarious-margined; the innermost (uppermost) 22–23 mm long, 3–4 mm wide, narrowly triangular-lanceolate, acuminate, minutely puberulent without in upper portion, minutely ciliolate. Sepals with free expanded portion broadly lanceolate, acuminate, 12 mm long, 4 mm wide at base, membranous, 5-nerved, the lower portion attached to corolla tube for 15 mm long and 4 mm wide, hyaline throughout. Corolla yellow, 3 cm long; tube 12 mm long, 2.5–3 mm wide; laminate portion rhomboid, abruptly acute, 17 mm long, 9 mm wide at the widest portion, narrowed to claw 9 mm long, 2 mm wide. Anthers linear, bilobate at base, 10 mm long, 0.5 mm wide, prolonged at apex into a linear-oblong gland 1.5–

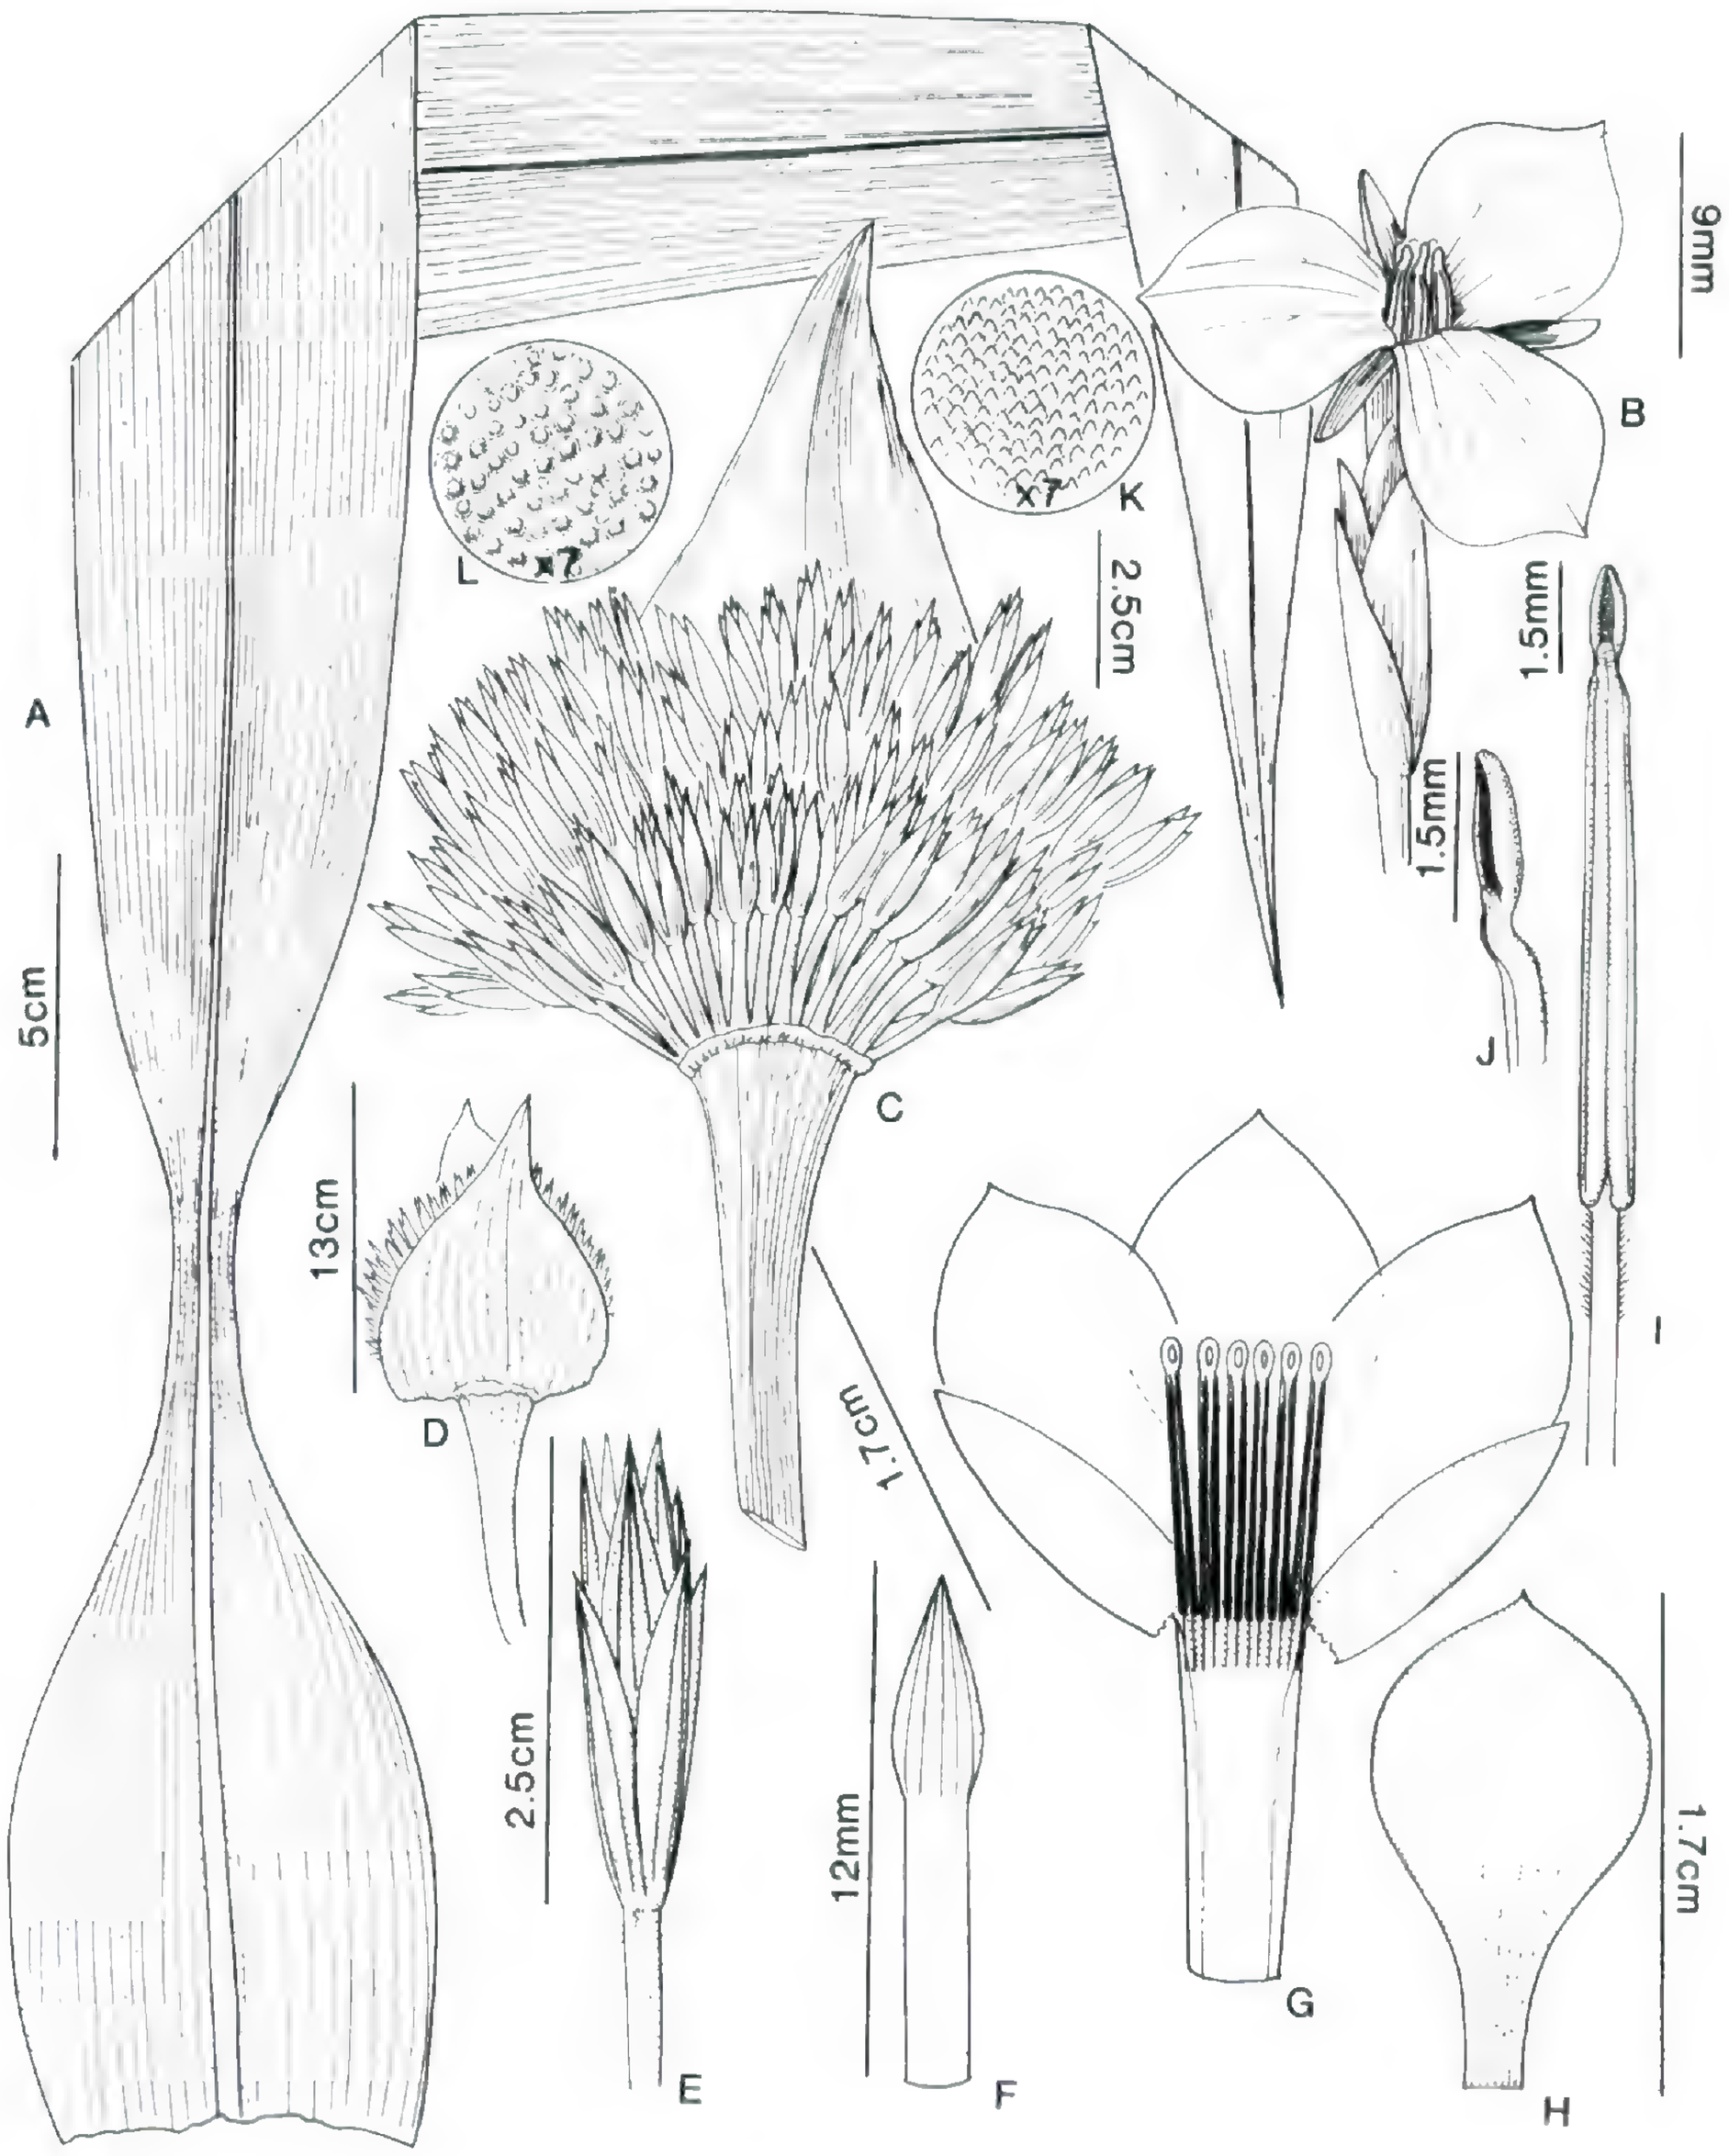

FIGURE 15. *Rapatea aracamuniana*.—A. Leaf.—B. Spikelet with open flower.—C. Inflorescence.—D. Inflorescence with bracts.—E. Fruit.—F. Corolla in bud.—G. Flower with corolla opened.—H. Petal.—I. Stamen.—J. Anther gland.—K. Detail of upper leaf surface.—L. Detail of lower leaf surface. (From *Liesner & Delascio 22197*.)

1.7 mm long, 0.4–0.5 mm wide. Filaments 4 mm long, 0.5 mm wide, pilosulous-ciliolate in the uppermost 2 mm. Style glabrous, 28 mm long, 0.3 mm wide, curved at apex, narrowed to a conical apex.

This species is related to *Rapatea steyermarkii* Maguire of extreme southeastern Venezuela in Estado Bolívar. Although similar in inflorescence, involucral bracts, and leaf shape and size, *R. aracamuniana* has filaments that are ciliolate (vs. glabrous in *R. steyermarkii*). The anthers, lowest bracteoles, and spikelets are longer in *R. aracamuniana*. The upper and lower leaf surfaces of *R. steyermarkii* are densely brown pubescent on the lower surface with elongate, crisp-villosulous, loose multicellular hairs, whereas in *R. aracamuniana* the lower surface has only brown glandular dots between smaller, pale punctations. In *R. steyermarkii* the upper leaf surface has short, divaricate, pointed hairs irregularly scattered on the nerves in addition to a minutely papillate surface, whereas the upper surface in *R. aracamuniana* is densely verruculose-papillate throughout.

Since *Rapatea steyermarkii* was originally described without flowers, the following description (taken from a specimen of *Holst & Liesner 2847* from Río Acanan, Estado Bolívar) is added to provide details lacking from the original description.

RAPATEA STEYERMARKII

Sepalis (parte libera) 19–20 mm longis; antheris 5 mm longis, 0.7 mm latis; filamentis 3 mm longis omnino glabris; stylo 15 mm longo glabro.

RUBIACEAE—contributed by Julian Steyermark

Cephalodendron aracamuniensis Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, ravine forest at edge of tepui, 01°26′N, 65°47′W, 1,550 m, 17 Oct. 1987, *R. Liesner & F. Delascio 22064* (holotype, MO; isotype, VEN).

Arbor 4–6-metralis; ramulis dense hirsutis pilis divaricatis 2 3 mm longis instructis; foliorum laminis late obovatis apice abrupte acutis basi rotundatis vel subcordatis 32–35 cm longis prope medium 16–26 cm latis, supra ferrugineo-hirsutis pilis 2 3 mm longis onustis; venatione tertiaria supra conspicue rugosa; pedunculo dense ferrugineo-hirsuto pilis 2–3 mm longis patentibus ornato; calyce 15 mm longo dense antrorse adpresso-pubescenti pilis 1 2.5 mm longis praedito, lobis quinque inaequalibus; corolla subhypocrateriformi 35–37 mm longa (tubo 27 mm longo, lobis 8 mm longis), tubo dense pubescenti pilis adpressis retrorsis 0.5 mm longis munito; antheris 7 mm longis.

Tree 4–6 m tall, stems of the branches ferruginous-brown hirsute with spreading hairs 2–3 mm long. Stipules at the stem apex prominent, oblong-obovate, rounded at apex, 5.5–7 cm long, 3–3.5 cm wide, densely ferruginous-brown hirsutulous. Leaf blades subcoriaceous, both sides rugulose, broadly obovate, abruptly acute at apex, rounded-subcordate at base, 32–35 cm long, 16–26 cm wide at or near the base, lower portion of upper surface hirsute with erect to ascending ferruginous hairs 2–3 mm long, becoming more shortly pubescent in age, lower surface densely villous-hirsute with ferruginous-brown hairs, the midrib and main lateral nerves with denser, loosely spreading to subretrorse hairs 2–3 mm long. Lateral nerves 16–20 each side, arcuate-ascending at 35–40°, inconspicuously anastomosing near the margin, elevated below, impressed above; tertiary venation conspicuously rugose on lower surface. Inflorescence capitate, globose, at anthesis 3 cm long, 3.5 cm wide, up to 4 cm long and 4.5 cm wide at postanthesis, enveloped at anthesis by 2 suborbicular rounded bracts 3 cm long, these 3.5–4 cm wide, densely ferruginous hirsute. Peduncle 9–29 cm long, 5–6 mm wide, densely ferruginous hirsute with loosely spreading hairs 2–3 mm long. Bract subtending base of hypanthium lanceolate, acute 5 mm long, 1.5 mm wide. Hypanthium turbinate-oblong, in anthesis 6 mm long, 4.5 mm wide, densely ferruginous hirsute with ascending hairs 2.5–3 mm long. Calyx and hypanthium 19–20 mm long in anthesis. Calyx tubular-cylindric, 15 mm long, 5–6 mm wide, the tube in anthesis 13 mm long, 3.5 mm wide, appressed-pubescent with hairs 1–2.5 mm long; calyx lobes 5, unequal, 4 lobes broadly suborbicular, rounded, 1.5 mm long, 2 mm wide, the 5th lobe broadly subtriangular-ovate with a 0.5–0.6 mm long caudate appendage, densely short-sericeous within. Corolla white, subsalverform, 35–37 mm long, the tube 27 mm long, 3 mm wide in the upper 15 mm, 1.5 mm wide in the lower 10–12 mm, densely pubescent without, with appressed hairs 0.5 mm long; corolla lobes 8 mm long, 2 mm wide, densely antrorsely pubescent without, glabrous within in the basal 2.5 mm, pilose with spreading hairs 0.5–0.7 mm in the adjacent 11 mm, glabrous in the uppermost 12 mm. Stamens inserted in the upper ¾ of the corolla tube; anthers linear, 7 mm long, 0.5 mm wide, slightly bilobate-rounded at base; filaments 1 mm long, glabrous, inserted 10 mm below base of corolla lobes. Style 8.5 mm long, glabrous. Disk glabrous. Fruits not seen.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, ravines near edge of tepui, 01°32′N, 65°49′W, 1,400 m, 31 Oct. 1987, *R. Liesner & G. Carnevali 22682* (MO, VEN).

Cephalodendron was known until now as a monotypic genus endemic to the summit of Cerro de la Neblina in Venezuela. The new taxon differs from *C. globosum* Steyerm. in the longer, spreading-hirsute pubescence of stems, peduncles, petioles, and lower leaf surface; longer calyx, corolla, and anthers; and cylindric calyx tube 3¼–3½ times longer than broad.

Coussarea liesneri Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, slope forest, Quebrada Camp, 01°24′N, 65°38′W, 600 m, 21 Oct. 1987, *R. Liesner & F. Delascio 22262* (holotype, VEN; isotype, MO).

Arbor 8-metralis; foliis oblongo-ellipticis apice abrupte acuminatis, acumine usque ad 1.5 cm producto, basi acutis 22–33 cm longis 7–14 cm latis ubique glabris, nervis lateralibus utroque latere 10–12; petiolis 1.5–2 cm longis; inflorescentia paniculata, pedunculo incluso 8–

10 cm longa basin versus 6 cm lata; pedunculo 4–4.5 cm longo puberulento; calyce 4-lobato profunde campanulato 2.5 mm longo superne 2 mm lato extus minute puberulento, lobis inaequalibus squarrosis sublanceolatis apice obtusis 0.5 mm longis puberulento-ciliatis; hypanthio minute puberulento, staminibus basi corollae insertis.

Tree 8 m tall. Leaf blades oblong-elliptic, 22–33 cm long, 7–14 cm wide, glabrous throughout, abruptly acuminate at apex (the acumen up to 1.5 cm long), acute at base; principal lateral nerves 10–12 each side, elevated below, slightly elevated or impressed above; tertiary venation reticulate and elevated below, inconspicuous above. Petiole 1.5–2 cm long, 2.5–3.5 mm wide, glabrous. Inflorescence terminal, paniculately branched, 8–10 cm long including the peduncle, 6 cm broad at the base, with 3 main divaricate tiers of lateral axes. Flowering portion of inflorescence 6 cm long with 7–10 axes, the lower 4 proximate, 1–2 cm long and branched into 3 secondary axes bearing capituliform clusters 7–10 mm broad, each containing 5–10 sessile flowers; the other tiers of axes shorter, 1–3 cm long; rachis and axes minutely puberulent. Peduncle 4–4.5 cm long, 2–2.5 mm wide, puberulent. Calyx 4-lobed, deeply campanulate, 2.5 mm long, 2 mm wide at summit, narrowed below, minutely puberulent without, sparsely puberulent at the summit margin, glabrous within; lobes unequal, squarrose, sublanceolate, obtuse at apex, 0.5 mm long, 0.2 mm wide, puberulent-ciliate; hypanthium turbinate, 1.5 mm long, 1 mm wide at summit, minutely puberulent without. Corolla cylindric, apically narrowed, 6 mm long, 1.5 mm wide (in bud); corolla lobes 3 mm long (in bud). Stamens inserted at base of corolla tube; anthers 2.5 mm long.

This species is related to *Coussarea rudgeoides* Rusby of Bolivia and Peru, from which it differs in the denticulately lobed calyx with pubescent, squarrose lobes; longer peduncle; longer calyx tube exceeding the hypanthium; and insertion of the filaments at the base of the corolla tube. In *C. rudgeoides* the filaments are attached in the lower ¼ of the corolla tube, and the calyx tube is about as long as the hypanthium.

Neblinathamnus aracamunianus Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, savanna at edge of tepui, 01°26′N, 65°47′W, 1,550 m, 19 Oct. 1987, *R. Liesner & F. Delascio 22153* (holotype, MO; isotype, VEN).

Suffrutex 0.5-metralis; foliis ternatis elliptico-oblongis apice obtusis vel subacutis majoribus 3.5–4.2 cm longis 1.3–2.2 cm latis subtus praeter areolas foveolatas minute albido-pubescentes glabris; calycis lobis spathulato-linearibus apicem versus dilatatis apice subacutis 4 mm longis superne 0.5–0.7 mm latis extus albido-hispidulis, marginibus hispido-ciliatis; corollae tubo 16 mm longo extus glabro intus prope antheras minute papilloso-puberulentoaliter glabro, lobis ovato-oblongis apice late rotundatis 5 mm longis 3 mm latis.

Suffruticose plant 0.5 m tall. Stems slender, densely introrsely hirtellous. Leaves ternate, elliptic-oblong, mainly obtuse to subacute at apex, acute at base, the larger and principal leaf blades 3.5–4.2 cm long, 1.3–2.2 cm wide, glabrous above except for sparse, appressed hairs in the sulcate midnerve, paler and mainly glabrous below except for depressed, minute, white pubescent, foveolate areas within the reticulate venation; principal lateral nerves 4–6 each side, inconspicuous to obsolete above, the midnerve and lateral nerves glabrescent or with sparse, appressed trichomes 0.2–0.5 mm long; tertiary venation obsolete above, finely reticulate below and impressed, the areoles in depressed foveolate areas with circles of minute white trichomes. Petiole 2–3 mm long, moderately to densely appressed-pubescent with pale hairs. Inflorescence terminal or axillary, the flowers solitary or in pairs. Pedicels 1–2 mm long. Hypanthium turbinate, 2 mm long, 1.5 mm wide, densely gray hirtellous. Calyx lobes linear-spathulate, broadened near the subacute apex, subacute at base, 4 mm long, 0.5–0.7 mm wide in upper half, hispidulous without, with gray-white pubescence, glabrous within, the margins hispid-ciliate. Corolla tube red, greenish white on lobes, 16 mm long, slenderly salverform, the tube 12 mm long, 2 mm wide, glabrous without, minutely papillose-puberulent within for 3 mm in the zone of the anthers, elsewhere glabrous; corolla lobes 5, ovate-oblong, rounded at apex, 5 mm long, 3 mm wide. Anthers linear, 2 mm long, inserted ⅔ way up tube; filaments free for 1 mm, attached 3 mm to tube 4 mm above its base. Style 10 mm long, glabrous; stigmas 2 mm long.

The genus *Neblinathamnus* was originally described by Steyermark (1963) with two species known, *N. argyreus* from Venezuela on Cerro de la Neblina and *N. glabratus* from adjacent northern Brazil on Serra Pirapucú. This third species differs from the other two in its shorter corolla; larger leaf blades with subacute or obtuse apices; and shorter, spathulate-linear, subacute calyx lobes, which are more dilated at the apex, dorsally pubescent, and more abundantly ciliolate.

Remijia reducta Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept.

Río Negro, Cerro Aracamuni, summit, Proa Camp, savanna near edge of tepui, 01°32′N, 65°49′W, 1,400 m, 25 Oct. 1987, *R. Liesner & G. Carnevali 22407* (holotype, MO; isotype, VEN). Figure 16.

Frutex 0.5–1-metralis; ramulis juvenilibus dense hirsutis pilis antrorsis; foliis parvis revolutis lanceolato-ellipticis vel elliptico-oblongis apice obtusis vel subacutis, basi acutis 4–10 cm longis 2–3 cm latis, supra tenuiter rugosis subtus dense tomentoso-pilosis; petiolis 2–9 mm longis dense adpresso-hirsutis; inflorescentia valde abbreviata, floribus solitariis; pedunculo 1–2 mm longo dense ferrugineo-hirsuto; calyce 1–2 mm lobis deltoideis minutis; corolla hypocrateriformi, tubo 11 mm longo extus dense hirsuto pilis antrorse adpressis 3 mm longis praeddito, intus glabro; lobis quinque lineari-lanceolatis acutis 10–12 mm longis 2–3 mm latis; antheris 3.5 mm longis; capsulis maturis 13–18(–32) mm longis; seminibus 5–6.5 mm longis, corpusculo suborbiculari 3 mm longo, alis 1–2 mm latis.

Shrub 0.5–1 m tall. Stems antrorsely densely hirsute with appressed to ascending ferruginous hairs; terminal stipule ovate-oblong to broadly ovate, obtuse or rounded, 10–17 mm long, 5–14 mm wide, densely appressed-hirsute with elongate ferruginous-brown hairs 1.5–2 mm long. Internodes 3–6 mm long. Leaf blades coriaceous, drying dark above and ferruginous-brown below, revolute, lance-elliptic to elliptic-oblong, obtuse to subacute at apex, acute at base, 4–10 cm long, 2–3 cm wide, rugulose or bullate and glabrous above at maturity, densely hirsutulous with subappressed to ascending hairs in early stages, densely tomentose below, midrib and lateral nerves with densely appressed, crisp, longer hairs; lateral nerves 10–12 each side, slightly to deeply sulcate above, finely and minutely reticulate and elevated below. Petioles 2–9 mm long, 1–2 mm wide, densely appressed-hirsute. Internodes 3–6 mm long. Inflorescence greatly abbreviated, lateral, the flowers solitary, one on each side. Peduncle at anthesis 1–2 mm long, in fruit 5–7 mm long, densely and antrorsely ferruginous hirsute. Hypanthium at anthesis 2–3 mm long, in fruit cylindric to oblanceolate and elongating to 9 mm long, densely antrorsely ferruginous-hirsute. Calyx 1–2 mm long, subtruncate or with minute, broadly deltoid lobes, glabrous within. Disk equaling the calyx. Corolla white, salverform, tube 11 mm long, 3 mm wide above, 2.5–3 mm wide below the middle, densely buff-brown hirsute with antrorsely appressed hairs 33 mm long, glabrous within; lobes 5, recurved, linear-lanceolate, acutish, 10–12 mm long, 2–3 mm wide, densely antrorse-hirsute without, glabrous within. Stamens attached to tube slightly below the middle; anthers linear, 3.5 mm long, 0.7 mm wide; filaments 4 mm long, attached 6.5 mm above base of tube, glabrous. Style 3 mm long, glabrous; stigmas linear, 2 mm long. Capsule at maturity obovate or broadly oblong, 13–18(–32) mm long; valves conspicuously osseous, bifid at apex, densely brown hirsute without, glabrescent, 8–13 mm wide; seeds few, wings pale buff-brown, body pale brown, finely cellular on surface, oval or subovate, rounded or subtruncate at one or both ends, often more narrowed at the other end, 5–6.5 mm long, 2.7–3 mm wide; wings 1–2 mm wide.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, low savanna, 01°26′N, 65°47′W, 1,550 m, 17 Oct. 1987, *R. Liesner & F. Delascio 22045* (MO, VEN).

This species differs from other species of *Remijia* by having solitary flowers. It is further distinguished by its small leaf blades, short petioles, densely ferruginous tomentose lower leaf surface with strongly reticulate tertiary venation, finely rugulose upper leaf surface, and relatively small seeds.

THEACEAE—contributed by Julian Steyermark (*Bonnetia*) and Brian Boom (*Ternstroemia*)

Bonnetia liesneri Steyerm., sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, savanna with small to large patches of forest and stream, 01°26′N, 65°47′W, 1,550 m, 18 Oct. 1987, *R. Liesner & F. Delascio 22105* (holotype, MO; isotype, VEN). Figure 17.

Suffrutex 0.5-metralis; foliis anguste oblanceolatis vel anguste ellipticis apice ut videtur subacutis vel obtusiusculis autem sub microscopio emarginulato-rotundatis 18–30 mm longis 4–8 mm latis; sepalis anguste-elliptico-lanceolatis aristato-oblongis apice rotundatis 11–12 mm longis 3–4 mm latis; style simplice vix 3-lobulato 8 mm longo.

Subshrub 0.5 m tall with spreading branches. Leaves clustered at the tips of the branches, narrowly oblanceolate to narrowly elliptic, seemingly subacute or obtusish at apex, but under 20× magnification rounded with an emarginulate summit, attenuate to the base, 18–30 mm long, 4–8 mm wide, glabrous throughout, leaf margin microscopically repand, cartilaginous, shortly 1–2 mm petiolate; midrib slightly elevated below, obsolete above; lateral nerves and tertiary venation obsolete. Flowers solitary near the summits of the branches. Peduncle ancipital, ebracteolate, mainly 13–15 mm long (sometimes much longer), glabrous. Sepals

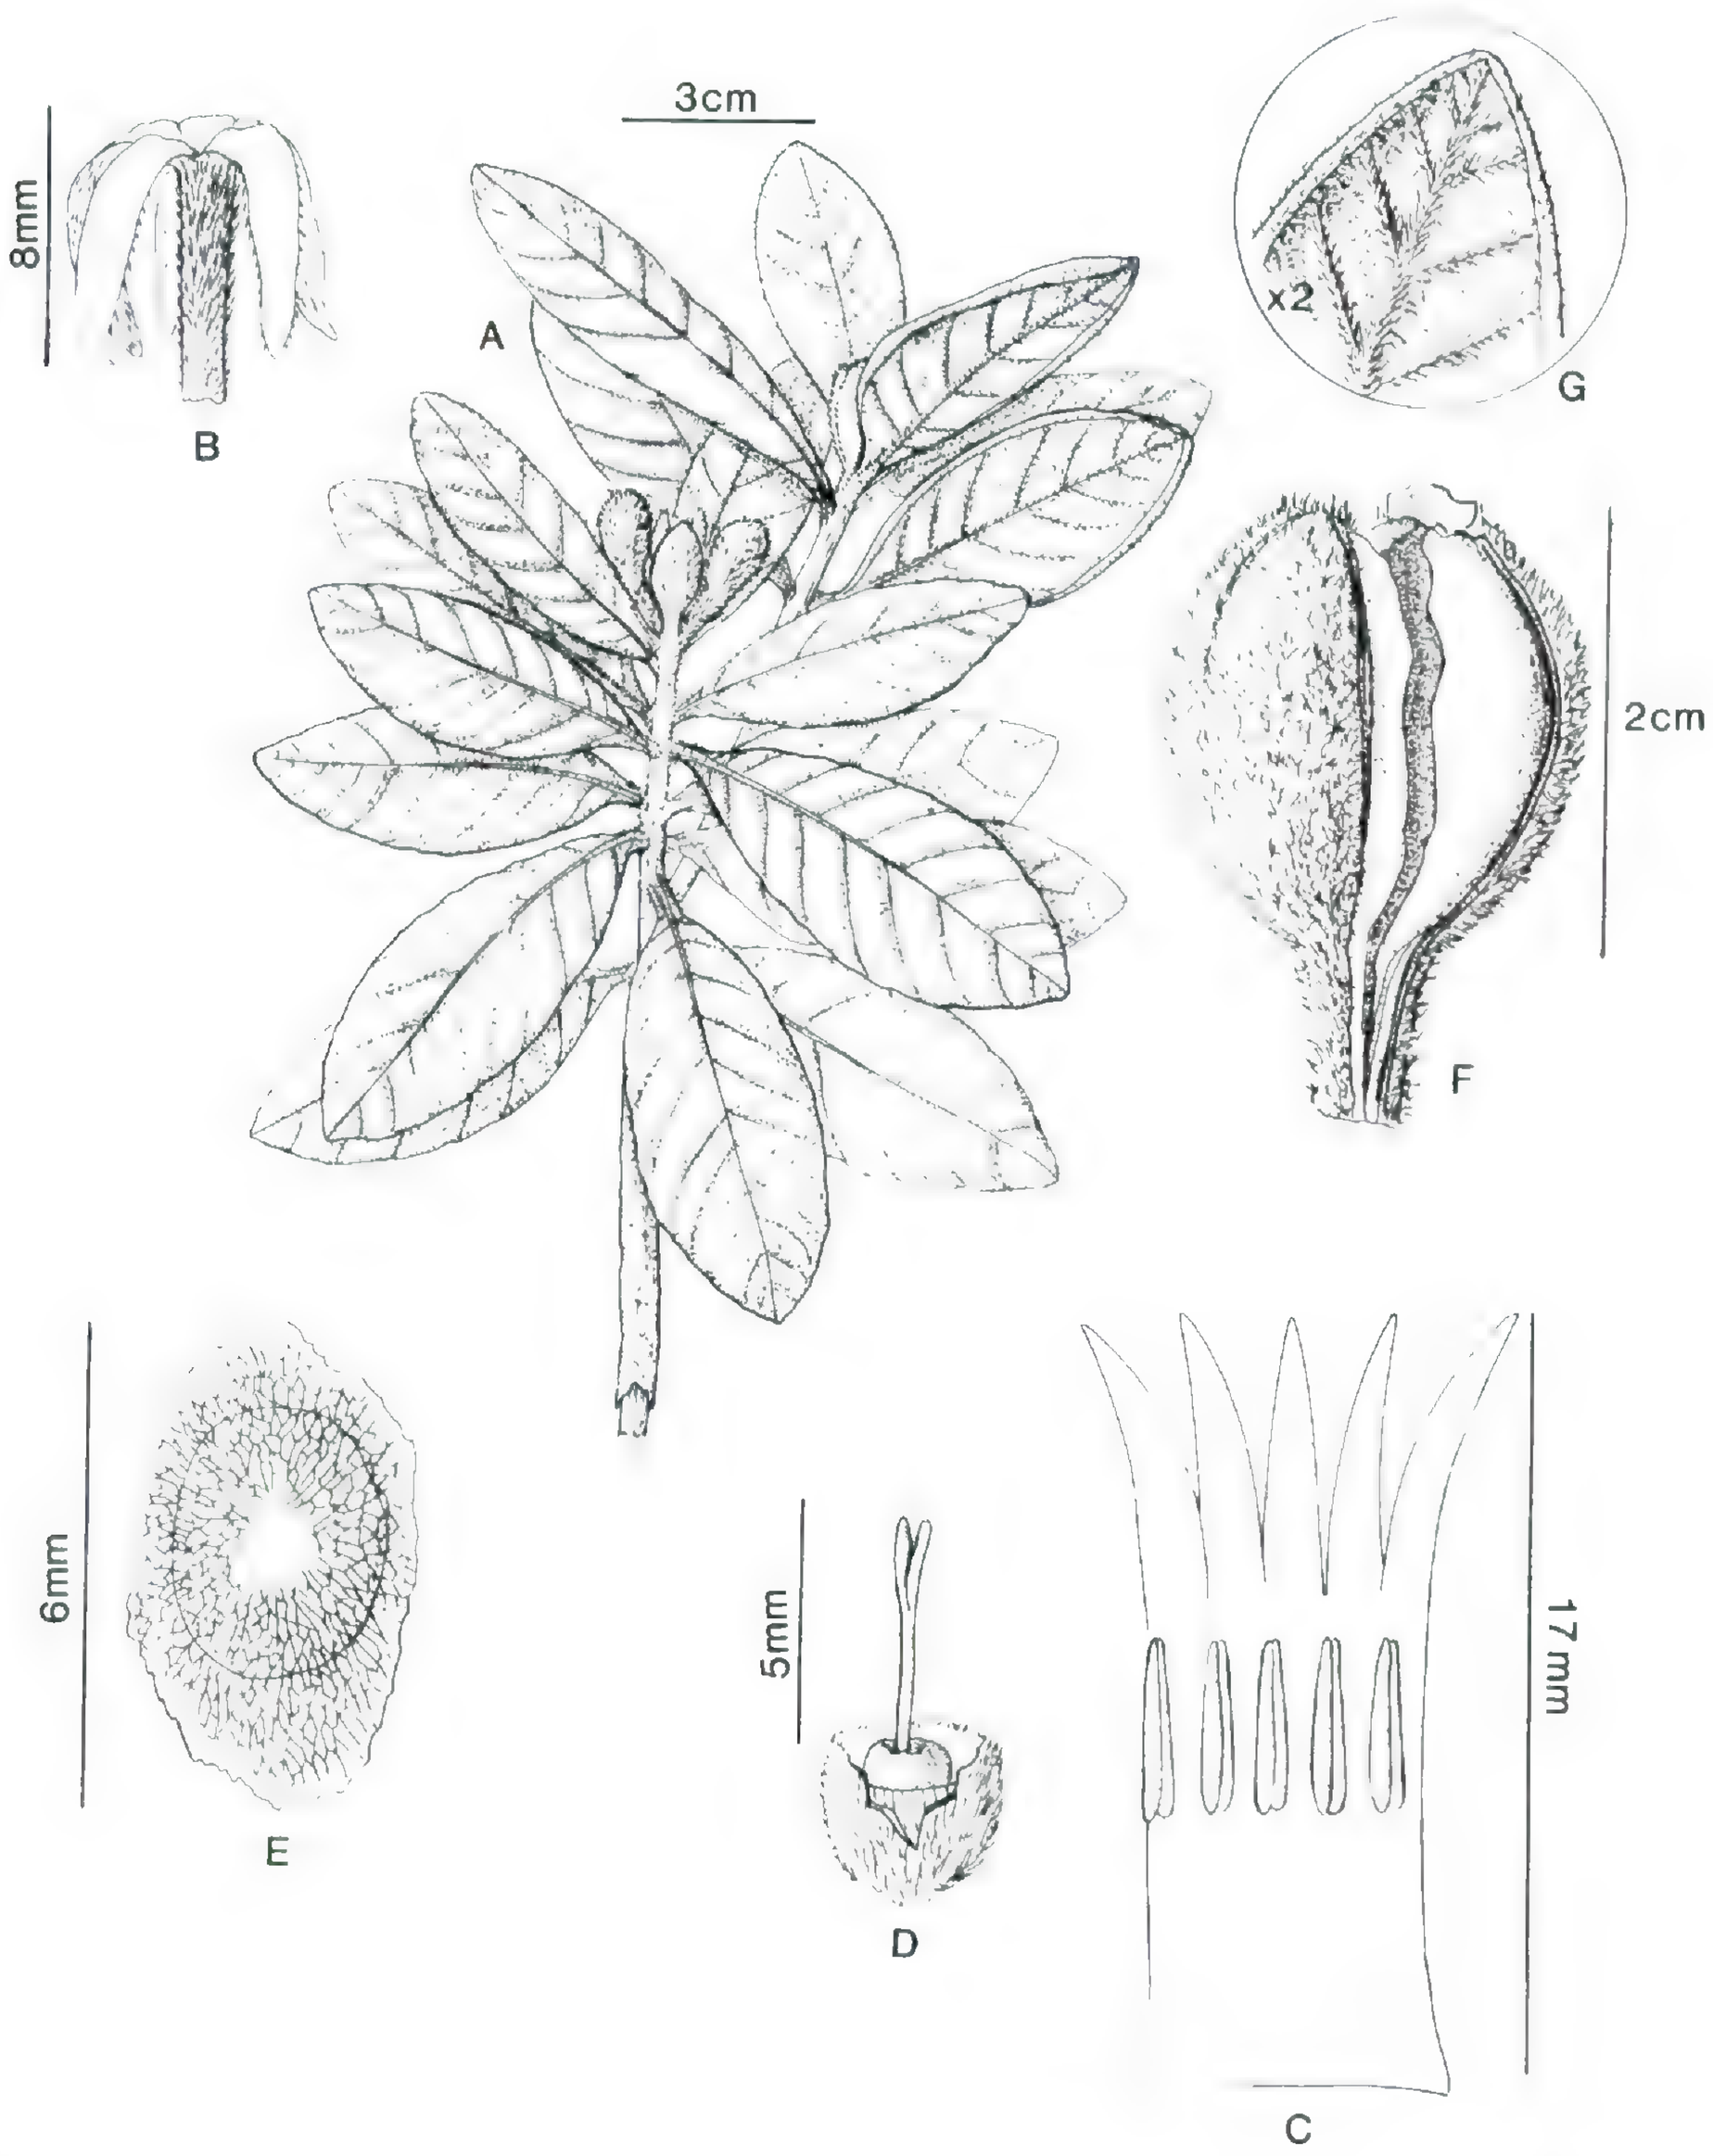

FIGURE 16. *Remijia reducta*.—A. Habit of branch.—B. Corolla.—C. Corolla opened.—D. Pistil with calyx cut away.—E. Seed.—F. Fruit.—G. Detail of lower leaf surface. (From *Liesner & Carnevali 22407*.)

narrowly elliptic-lanceolate to ovate, aristate-acuminate at apex, acute at base, 11–12 mm long, 3–4 mm wide at the middle, entire. Stamens numerous; anthers suborbicular, slightly longer than broad, 0.7 mm long, 0.5 mm broad. Style 8 mm long, undivided, merely shallowly 3-lobulate at the apex. Ovary (post-anthesis) ovoid, 5 mm long, 3 mm wide. Fruit ovoid, 3-celled, tapering to the persistent style, 10 mm long.

This species is most similar to *Bonnetia huberiana* Steyerm. of the Chimantá Massif, Estado Bolívar, but differs by having undivided, shallowly three-lobulate style; larger petals; larger, aristate-acuminate, entire sepals; and microscopically rounded emarginulate leaf apex.

Ternstroemia guanchezii Boom, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Atures, transecto desde matorral ribereño hasta bosque bajo ralo, en la margen izquierda del caño "Cabeza de Manteco," afluente del Río Autana, en el "Raudal Manteco," 04°52′N, 67°27′W, 100–120 m, 10 Nov. 1984, *F. Guánchez & E. Melgueiro 3447* (holotype, NY; isotype, TFAV). Figure 18.

eral eglandular cilia), the margin black glandular-serrulate; calyx lobes 5, free, cymbiform, 3.5–4 × 3–3.5 mm, the margin scattered black glandular-serrulate on outer lobes, entire on inner 3 lobes; corolla of 5 free petals, these ovate to lanceolate, 3.5–4 × 1–1.5 mm, apex obtuse, margin entire; androecium of ca. 24 uniseriate stamens, free from corolla; filaments of varying lengths, 0.3–1 mm long; anthers 0.6–1 mm long, basifixed, thecae parallel, dehiscence introrse; gynoecium with terete stigma and style, 2.5 mm long, ovary 1 × 1(–1.2) mm, 2-locular with 2 pendulous ovules per locule, the ovules 0.5–0.6 × 0.1–0.2 mm. Fruits unknown.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, slope, Quebrada Camp, in area of rapids flowing over laja, 01°24′N, 65°38′W, 600 m, 20 Oct. 1987, *R. Liesner & F. Delascio 22236* (MO, NY, VEN).

This distinctive species, with graceful, subopposite to opposite branchlets and small, fasciculate flowers, is known from lower to middle elevations of the western Venezuelan Guayana in forests along streams running through igneous rocks known locally as "lajas." The new species is named in honor of Francisco Guánchez, former director of the Herbario TFAV in Puerto Ayacucho, who first collected this species in 1984.

Ternstroemia maguirei Boom, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Cerro de la Neblina, south slope of Cumbre Camp, caño toward Cañon Grande, occasional on exposed rock outcrop, 1,500 m, 16 Jan. 1954, *B. Maguire, J. Wurdack & G. Bunting 37347* (holotype, NY; isotype, VEN). Figure 19.

Frutex vel arbor 1–6 m altus, 6 cm diametro, ramulis fasciculatis angularibus ravido-fuscis; foliis ellipticis ad ovatis vel obovatis (7.5–)10–14 × (3.8–)4.5–6.7 mm aliquantum asymmetricis apice acutis vel rotundis basi acutis vel rotundatis, petiolo (5–)8–13(–15) mm longo, costa superne canaliculata infra prominula, venis 10–15(–19)-jugis utrinque vix manifestis, lamina inferne fusco-punctata; floribus geminatis subterminalibus, pedunculo 11–38(–50) mm longo; bracteolis duabus subopppositis cymbiformibus 5.5–6 × 3.5–4 mm apice acutis, margine atroglanduloso-serrulatis, calycis lobis 5 liberis perlate ovatis (5–)7–8.5 × (6.5–)8–9 mm, duabus exterioribus margine atroglanduloso-serrulatis, tribus intimis fere eglanduloso-integris; corollae lobis 5 basi per ca. 3 mm connatis, lobis liberis lanceolatis ca. 5 × 3.5 mm apice acuminatis margine integris; staminibus ca. 37 uniserialis basifixis basi connatis, filamentis 0.8–1 mm longis, antheris 2 mm longis, thecis parallelis 1–1.5 mm longis introrsus dehiscentibus, connectivo ultra thecas producto, stigmatibus et stylis teretibus 8 mm longis; ovario biloculari, ovulis 0.4–0.2 mm; fructibus laevibus perlate ovoideis 2–3-locularibus 15 × 16 mm, stylo persistenti ca. 5 mm longo, parietibus 2.5–3 mm crassis; seminalibus 16, 8–9 × 4.5 mm.

Shrub or small tree 1–6 m tall, 6 cm diam., branchlets fasciculate, angular in cross-section, grayish brown. Leaves distributed along branchlets, coriaceous, elliptic to ovate or obovate, (7.5–)10–14 × (3.8–)4.5–6.7 mm, slightly asymmetrical, apex acute to rounded, base acute to rounded, petiole (5–)8–13(–15) mm long, midrib canaliculate above, evident the entire length, prominent below, the veins 10–15(–19) pairs, scarcely visible above and below, blade below with scattered dark glandular punctations. Flowers subterminal, paired, peduncles 11–38(–50) mm long; bracteoles 2, cymbiform, subopposite, unequal in size, 5.5–6 × 3.5–4 mm, apex acute, black gland-tipped, the margin black glandular-serrulate; calyx lobes 5, free, widely depressed ovate, (5–)7–8.5 × (6.5–)8–9 mm, the margin scattered black glandular-serrulate on outer 2 lobes, entire to slightly glandular on inner 3 lobes; corolla of 5 petals, these fused basally for ca. 3 mm with lanceolate lobes ca. 5 × 3.5 mm, apex acuminate, margin entire; androecium of ca. 37 uniseriate stamens, these free from corolla, connate basally; filaments of varying lengths, 0.8–1 mm long; anthers 2 mm long, basifixed, thecae parallel with apiculate connective, this 1–1.5 mm long, dehiscence introrse; gynoecium with terete stigma and style, 8 mm long, ovary 2.5–3.5 mm, 2-locular with 8 pendulous ovules per locule, the ovules 0.4 × 0.2 mm. Fruits smooth, widely depressed-ovoid, 15 × 16 mm, persistent style 5 mm long, fruit wall 2.5–3 mm thick, 2–3-locular, 16-seeded, the seeds 8–9 × 4.5 mm.

This new species is notable for its inflorescence of strictly one pair of flowers and its relatively large, smooth capsular fruits that are apparently nondehiscent. It is restricted to elevations above 800 m on sandstone in southern Venezuelan Guayana (Cerros Neblina, Aracamuni, and Duida). It is named in honor of Bassett Maguire, Senior Scientist Emeritus of the New York Botanical Garden and inveterate botanical explorer of the Guayana Highland. Maguire and colleagues first collected this species in 1954, and he first directed my attention to *Ternstroemia* as a genus in need of taxonomic study.

XYRIDACEAE—contributed by Robert Kral (VDB)

Abolboda scabrida Kral, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, medium height, semi-open forest, 01°32′N, 65°49′W, 1,400 m, 28 Oct. 1987, *R. Liesner & G. Carnevali 22598* (holotype, VEN; isotypes, MO, VDB). Figure 20.

Herba perennis densicaespitosa, praeter inflorescentiam et bases scabrida et scabridorugosa. Radices spongiosae. Caules breves, ascendentes, usque ad 2–3 cm longi, basibus persistentibus veternorumfoliorum obtecti. Folia extima rosularum praesertim vaginalia, anguste triangulata; folia principalia erecta vel expansa, leviter excurvata, 3 6 cm longa, ad basin dilatata, ca. 5-costata, sursum abrupte contracta, 2–3-costata; laminae 0.5–1 mm latae, pallide virides, leviter compressae, transversim irregulariter rugosae et tuberculatae; apices gradatim vel abrupte contracti, incrassati, ad apicem obtusati vel excurvato-mucronati; margo leviter vel valde incrassata, scabra; paginae superiores planae aut leviter convexae, inferiores concavae vel planae aut prominenter 2 3-costatae. Scapi unici, scabrosi, 6 10 cm alti, 0.5–0.7 mm lati, a basin leviter compressi vel tricostati et sulcati, ad apicem teretes. Vaginae scaporum erectae, lineari-lanceolatae, subulatae, convexae, leviter striatae, inaequales, 2-jugatae, pari infimo basali, pari supero ca. ⅔ distanti a basi scaporum, vaginis exterioribus 1–1.5 cm longis, longitudine ¾ ⅘ interiores aequantibus. Spica anguste turbinata, 1.1 -1.4 cm longa, pauciflora (flores vulgo 4); bracteae 2-jugatae, subdecussatae, lanceolatae, incrassato-subulatae, 1 -1.4 cm longae, convexae, a medio ad apicem carinatae, scabridulae, ad apicem obusae, medio virides, marginibus late scarioso-marginatae. Sepala 2, lateralia, subopposita, lanceolata, inaequilateralia, ca. 1 cm longa, curvata, anguste acuta, a medio ad apicem acute carinata scabridula. Corolla azurea, ca. 1 cm longa. Staminodia bibrachiata, brachiis planis, anguste oblongis, ca. 1 mm longis. Antherae oblongae ca. 1 mm longae; filamenta ca. 1.5 mm longa. Appendices stylorum 3, recurvatae, clavatae, 1 reducta. Capsula obovoidea, ca. 2.5 mm longa, obscure trilobata, valvis ad apicem inflexis et erosis. Semina late asymmetrice obovoidea, ca. 0.5 mm longa, longitudinaliter valde 12–14-costata, anthracina.

Perennial, densely cespitose herbs, all but the bases and inflorescence scabrid and scabrid-rugose. Roots spongy. Stems short, ascending, up to 2–3 cm long, the bases covered by old leaves. Outer leaves of a rosette for the most part sheath, narrowly triangular; principal foliage leaves erect to spreading, slightly excurved, 3–6 cm long, dilated at base, ca. 5-costate, then abruptly contracted above, 2–3 costate; blades 0.5–1 mm wide, pale green, somewhat compressed, transversely irregularly rugose and tuberculate; apices gradually to abruptly narrowed, thickened, at tip obtuse or excurved-mucronate; margin slightly thickened to very thickened, scabrid; upper surface flat to somewhat convex, the lower surface concave to flat or prominently 2–3-costate. Scape solitary, scabrous, 6–10 cm high, 0.5–0.7 mm wide, at base somewhat compressed to tricostate and sulcate, terete toward apex. Scape sheaths erect, linear-lanceolate, subulate, convex, slightly striate, unequal, in 2 pairs, the lower pair basal, the upper pair ca. ⅔ way up from scape base, the outer sheaths 1–1.5 cm long, ¾–⅘ as long as the inner sheaths. Spike narrowly turbinate, 1.1–1.4 cm long, few-flowered (flowers usually 4); bracts 2 pairs, subdecussate, lanceolate, thickened-subulate, 1–1.4 cm long, convex, carinate from middle to tip, scabridulous, obtuse at tip, medially green with margins broadly scarious-bordered. Sepals 2, lateral, subopposite, lanceolate, inequilateral, ca. 1 cm long, curvate, narrowly acute, sharply and scabridulously carinate from middle to tip. Corolla blue, ca. 1 cm long. Staminodia bibrachiate, the branches flat, narrowly oblong, ca. 1 mm long. Anthers oblong, ca. 1 mm long; filaments ca. 1.5 mm long. Stylar appendages 3, recurved, claviform, 1 appendage reduced. Capsule obovoid, ca. 2.5 mm long, obscurely trilobed, the valves inflexed and erose at apex. Seeds broadly asymmetrically obovoid, ca. 0.5 mm long, longitudinally strongly 12–14-ribbed, coal black.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, on edge of tepui in slope savanna, 01°26′N, 65°47′W, 1,550 m, 17 Oct. 1987, *R. Liesner & F. Delascio 22071* (MO, VDB, VEN).

This species is related to *A. acicularis* Idrobo & Smith, particularly var. *granularis* Maguire, but the foliage and scapes are rugose and scabrid (vs. smooth or granular), the sepal keels are scabridulous (vs. smooth or granular), the petals are blue (vs. white), and the seeds are smaller.

Negro, Cerro Aracamuni, summit, Proa Camp, savanna with small to large patches of forest, in savanna, 01°32′N, 65°49′W, 1,400 m, 25 Oct. 1987, *R. Liesner & G. Carnevali 22452* (holotype, VEN; isotypes, MO, VDB). Figure 21.

Herba perennis, densicaespitosa. Radices graciles. Caules breves. Folia rigida, erecta vel leviter expansa, anguste linearia, 30 55 cm longa, valde flexuosa et torta; laminae leviter compressae, in sectione transverssali ellipticae, vaginis 1 2-plo longiores, 2 2.5 mm latae, distincte paucicostatae; apices gradatim contracti, anguste incurvo-acuti, incrassati, ventraliter sulcati; margines leviter incrassatae, dense albotomentosae, a basi ad apicem ventraliter sulcatae; vaginae elongatissimae, convexae, obscure brunneolae, papilloso-rugulosae, valde apertae, a basi ad apicem gradatim contracti, eligulatae, marginibus longe ciliatis, pilis villosis, pallidis. Vaginae scaporum laminis ut in laminis foliorum. Scapi lineares, aliquantum compressi, torti, 4 7 dm alti, dense albotomentosi, in sectione transversali elliptici, ad apicem subteretes, prominenter pluricostati. Spicae late obovoideae vel turbinatae, obtusae, pluriflorae, bracteis convexis, firmis, ferrugineo-fuscis, spiraliter imbricatis, integris; bracteae steriles plures, triangulatae vel ovatae, 3–6 mm longae, subacutae, fertilibus breviores et in eas gradatim transientes, infimis ad apicem acutum retrorse albohirsutae; bracteae fertiles oblongo-ovatae, 7–9 mm longae, humiliter costatae. Sepala lateralia libera, subequilateralia, lanceolata, ca. 6 mm longa, curvata, acuta; ala carinalis fimbriociliata, lata, firma. Laminae petalorum obovatae, ca. 5 mm longae, luteolae, fere integrae. Staminodia bibrachiata, brachiis longe penicillatis. Antherae oblongae-lanceolatae, 2.5 mm longae, valde emarginatae et sagittatae; filamenta ca. 1 mm longa. Capsula ellipsoidea, acuminata, ca. 4 mm longa; placentatio axillaris. Semina numerosa, cylindrico-ellipsoidea, ca. 1 mm longa, translucida, pallide succinea, longitudinaliter spiraliter multicostata, ad apicem pallide et obtuse apiculata.

Densely cespitose perennial herb. Roots slender. Stems short. Leaves stiff, erect to slightly spreading, narrowly linear, 30–55 cm long, strongly flexuous and twisted; blades slightly compressed, in cross section elliptic, 1–2 times longer than the sheaths, 2–2.5 mm wide, distinctly few-nerved; apices gradually narrowed, narrowly incurved-acute, thickened, ventrally sulcate; margins somewhat thickened, densely white-tomentose, the inner edge sulcate from base to tip; sheaths much elongated, convex, dull brown, papillose-rugulose, very open, gradually narrowing from base to tip, eligulate, the edges long-ciliate with pale, villous hairs. Scape sheaths with blades as in foliage leaves. Scapes linear, somewhat compressed, twisted, 4–7 dm high, densely white tomentose, in cross section elliptic, apically subterete, prominently several-costate. Spikes broadly obovoid to turbinate, obtuse, several-flowered, the bracts convex, firm, red-brown, spirally imbricate, entire; sterile bracts several, triangular to ovate, 3–6 mm long, subacute, shorter than the fertile bracts and grading gradually into them, the lowest bracts retrorsely white-hirsute at the acute apex; fertile bracts oblong-ovate, 7–9 mm long, narrowly rounded apically; dorsal area distinct, triangular, 4–5 mm long, low-costate. Lateral sepals free, subequilateral, lanceolate, ca. 6 mm long, curved, acute; keel fimbriociliate, broad, firm. Petal blades obovate, ca. 5 mm long, yellow, nearly entire. Staminodia 2-branched, the branches long-penicillate. Anthers oblong-lanceoloid, 2.5 mm long, strongly emarginate and sagittate; filaments ca. 1 mm long. Capsule ellipsoid, acuminate, ca. 4 mm long; placentation axile. Seeds numerous, cylindric-ellipsoid, ca. 1 mm long, translucid, pale amber, longitudinally spirally multiribbed, at apex with a pale and obtuse apiculus.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Popa Camp, in low savanna, 01°26′N, 65°47′W, 1,550 m, 18 Oct. 1987, *R. Liesner & F. Delascio 22100* (MO, VDB, VEN).

Xyris liesneri Kral, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, savanna with small to large patches of forest especially along streams, in ravines and near edge of tepui, 01°32′N, 65°49′W, 1,400 m, 25 Oct. 1987, *R. Liesner & G. Carnevali 22086* (holotype, VEN; isotypes, MO, VDB). Figure 22.

Herba perennis dense caespitosa, caulibus multis, ramificantibus, ramificationibus usque ad 3 cm longis, praeter margines scaporum et apices foliorum glabra. Radices graciles. Folia principalia anguste lineari-gladiata, 10 20 cm longa, flabellate expansa, vaginis scaporum longiora; laminae planae, 1 2 mm latae, compressae, flavo-virentes vel ferrugineae, inconspicue multinervosae, praeter apices integrae; apices gradatim contracti, anguste curvato-acuti, longe ciliati, pilis ferrugineis; margines aciebus incrassatis, atroferrugineis, nitidis; vaginae carinatae, carinibus atroferrugineis, ciliolatis, lateribus multicostatis, ferrugineis, basin versus fuscatis vel atro-ferrugineis, marginibus in laminas gradatim convergentibus, infimis gradatim expansis, aciebus integris. Vaginae scaporum multicostatae, a medio ad apicem valde rufo-carinatae, laminis brevibus, rufo-ciliatis. Scapi graciles, flexuosi, 20 30 cm longi, leviter torti, leviter compressi, ad apicem in sectione transversali anguste elliptici, ancipites, bicostati, costis piloso-ciliatis, pilis brunneolis. Spicae ellipsoideae, 7 8 mm longae, obtusae, pauciflorae; bracteis integris, fere uniformibus, ferrugineis, spiraliter imbricatis, convexis; bracteae steriles 4, decussatae, ovatae, carinatae, ca. 3.5 mm longae; bracteae fertiles paucae, obovatae, ca. 4 mm longae;

apicem versus papillosae; area dorsalis inconspicue elliptica, atrobrunnea, leviter depressa, a medio indistincte 1-nervata. Sepala lateralia libera, valde inequilatera, lanceolata, 5 mm longa, acuta; ala carinali valida, usque ad apicum manifeste ciliata. Laminae petalorum late obovatae, ca. 5 mm longae, luteolae, prominenter laceratae. Antherae lanceolato-oblongae, 2 mm longae, emarginatae et sagittatae, filamentis longiores. Staminodia bibrachiata, brachiis longe penicillatis. Capsula ellipsoidea, ca. 2.5 mm longa, eseptata, placenta basali; semina cylindraceo-ellipsoidea, 1–1.3 mm longa, pallide et obtuse apiculata, atrobrunnea, longitudine obscurespiraliter multinervosae.

Dense cespitose perennial herb, the stems many, branching, the branches to 3 cm long, smooth except for leaf tips and scape edges. Roots slender. Principal foliage leaves narrowly linear-gladiate, 10–20 cm long, spreading flabellately, longer than the scape sheaths; blades flat, 1–2 mm wide, compressed, yellow-green to reddish brown, inconspicuously multinerved, entire except at tips; tips gradually narrowed, narrowly curved-acute, long-ciliate, the hairs reddish brown; margins with thickened, dark red-brown, shining edges; sheaths carinate, the carinas dark red-brown, ciliolate, the sides multicostate, red-brown, dull brown to dark red-brown toward base, the margins gradually narrowed into the blades, below gradually dilating, entire. Scape sheaths multicostate, strongly red-carinate from middle to tip, with short, red-ciliate blades. Scapes slender, flexuous, 20–30 cm long, slightly twisted, somewhat compressed, at tip in cross section narrowly elliptic, ancipital, bicostate, the costas pilose-ciliate, the hairs brownish. Spikes ellipsoid, 7–8 mm long, obtuse, few-flowered, the bracts entire, nearly uniform, red-brown, spirally imbricate, convex; sterile bracts 4, decussate, ovate, carinate, ca. 3.5 mm long; fertile bracts few, obovate, ca. 4 mm long, papillose toward tip; dorsal area inconspicuous, elliptic, dark brown, slightly depressed, medially indistinctly 1-nerved. Lateral sepals free, strongly inequilateral, lanceolate, 5 mm long, acute; keel strong to strongly ciliate up to the tip. Petal blades broadly obovate, ca. 5 mm long, yellow, strongly lacerate. Anthers lance-oblong, 2 mm long, emarginate and sagittate, longer than the filaments. Staminodia with 2 long-penicillate branches. Capsule ellipsoid, ca. 2.5 mm long, eseptate, the placenta basal; seeds cylindric-ellipsoid, 1–1.3 mm long, with a pale and obtuse apiculus, dark brown, longitudinally spirally multiribbed.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Cerro Aracamuni, summit, Proa Camp, savanna with small to large patches of forest, especially along streams, in savanna, 01°32′N, 65°49′W, 1,400 m, 25 Oct. 1987, *R. Liesner & G. Carnevali 22454* (MO, VDB, VEN).

This is a near relative of *Xyris frondosa* Maguire & Smith, a common high-altitude species of the tepuis of Estado Bolívar, particularly in habit and general leaf and spike dimensions. However, it is somewhat shorter-stemmed, its leaves are entire except at the very tips, and their margins more wirelike and thickened. The scapes, rather than being thick-edged and entire, are ancipital, the two costas thin, broad, and distinctly pilose-ciliate.

Xyris prolificans Kral, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Dept. Río Negro, slope of Cerro Aracamuni, Quebrada Camp, in area of rapids flowing over laja, 01°24′N, 65°38′W, 600 m, 20 Oct. 1987, *R. Liesner & F. Delascio 22200* (holotype, VEN; isotypes, MO, VDB). Figure 23.

Herba perennis caespitosa, tenella, glabra, laxa, rosulata, rhizomatosa. Rhizomata numerosa, gracilia, valde flexuosa, saepe ramificantia, breviter foliosa, ex axillis veternarum rosularum foliorum prodeuntia internodiis expositis. Radices graciles. Folia principalia rosularum leviter vel valde flabellate expansa, lineari-lanceolata, 3–7 cm longa, vaginis scaporum longiora; laminae planae, valde compressae, 0.8–1.5 mm latae, vaginis 1–3-plo longiores, longitudinaliter indistincte nervosae, olivaceae, a medio ad apicem gradatim contractae; apices anguste et acute incurvati; margines integri, tenues; vaginae carinatae, tenues, lateribus longitudinaliter multicostatis, marginibus in laminas gradatim convergentibus, apicibus ligula anguste acuta 1.5–2 mm longa ornatis, infimae gradatim dilatatae, a basi longe ciliatae. Vaginae scaporum laxae, apertae, tenues, ad apicem cuspidatae. Scapi subteretes, filiformes, spiraliter torti, 10–25 cm alti, ca. 0.4 0.5 mm crassi, olivacei, striati. Spicae lanceoloideae, in sicco turbinatae, 7 9 mm longae, pauciflorae, bracteis integris margine late scariosis, pallide brunneolis; bracteae steriles subdecussatae, ovatae, pari infimo carinatae, interiores breviores, 2.5 3 mm longae; bracteae fertiles oblongo-ovatae, 5–6 mm longae, convexae, rotundatae; area dorsalis viridis, ca. 2 mm longa, lanceolato-elliptica, medioindistincte costatis. Sepala lateralia libera, inequilateralia, curvata, 3–3.5 mm longa, acuta, ala carinali lata, a basi ad medium usque integra, a medio ad apicem usque indistincte lacerata. Laminae petalorum obovatae, 3 3.5 mm longae, luteolae, late rotundatae, valde erosae. Staminodia bibrachiata, brachiis dense longe penicillatis. Antherae oblongo-lanceolatae, ca. 1 mm longae, emarginatae et sagittatae; filamenta ca. 0.5 mm longa. Capsula matura non visa sed ovario placentationibus marginalibus et funiculis elongatis, praedito.

Cespitose, slender, smooth, lax, rosulate, rhizomatous herb. Rhizomes numerous, slender, strongly zig-zag, usually branching, short-leaved, from the axils of older rosette leaves and with the internodes exposed. Roots slender. Principal rosette leaves slightly to very flabellately spreading, lance-linear, 3–7 cm long, longer than the scape sheaths; blades flat, strongly compressed, 0.8–1.5 mm wide, 1–3 times longer than the sheaths, lon-

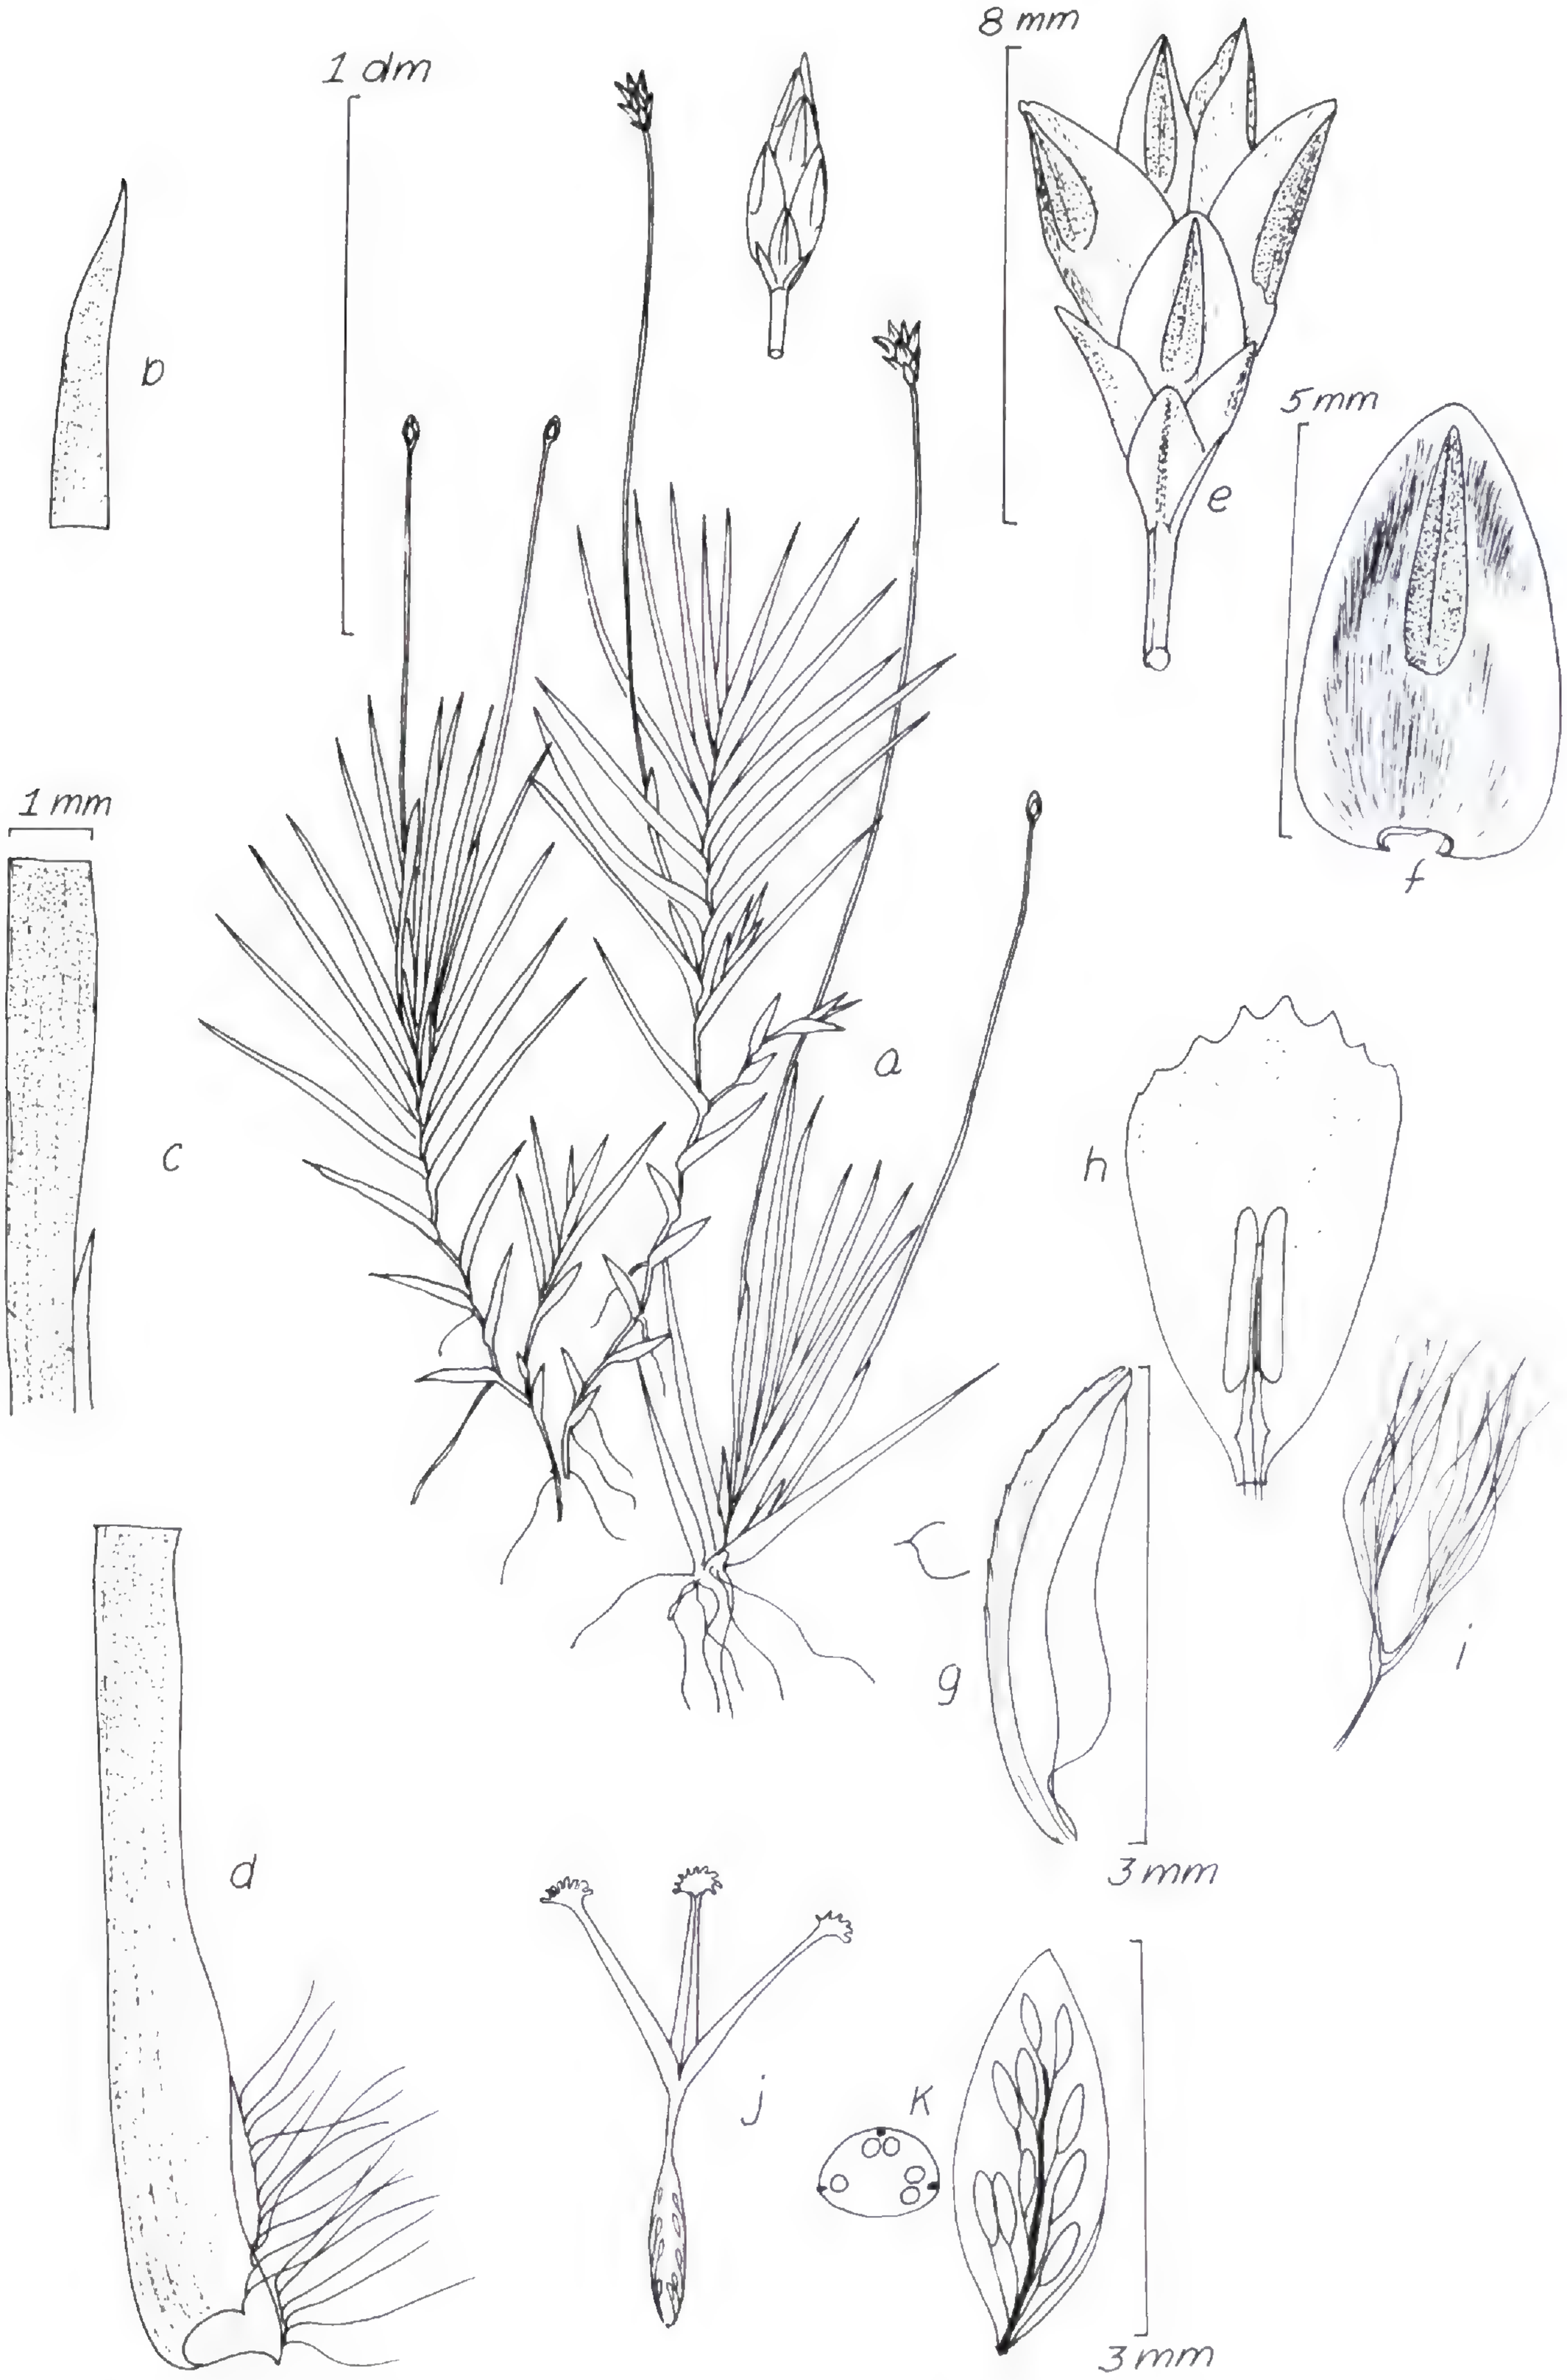

FIGURE 23. *Xyris prolificans.*—a. Habit with inset showing outline of mature spike.—b. Leaf tip.—c. Leaf blade sheath junction.—d. Leaf base. e. Dry spike.—f. Fertile bract.—g. Lateral sepal.—h. Petal blade and stamen.—i. Staminode.—j. Ovary and style.—k. Capsule valve (construction) showing placentation. (From *Liesner & Delascio 22200.*)

gitudinally indistinctly nerved, olivaceous, gradually narrowed from middle to tip; tips narrowly incurved-acute; margins entire, thin; sheaths carinate, thin, the sides longitudinally multicostate, the margins gradually narrowed, at apex producing a narrowly acute ligule 1.5–2 mm long, gradually dilating below, long-ciliate at base. Scape sheaths lax, open, slender and thin, cuspidate. Scapes subterete, filiform, spirally twisted, 10–25 cm high, ca. 0.4–0.5 mm thick, olivaceous, striate. Spikes lanceoloid, drying turbinate, 7–9 mm long, few-flowered, the entire bracts with broad, scarious pale brown borders; sterile bracts ca. 6, subdecussate, ovate, the lower pair carinate, shorter than the inner pairs, 2.5–3 mm long; fertile bracts oblong-ovate, 5–6 mm long, convex, rounded; dorsal areas green, ca. 2 mm long, lanceolate-elliptic, medially with an indistinct rib. Lateral sepals free, inequilateral, curvate, 3–3.5 mm long, acute, the keel broad, entire from base to middle, from middle to apex low-lacerate. Petal blades obovate, 3–3.5 mm long, yellow, broadly rounded, strongly erose. Staminodia bibrachiate, the branches densely long-penicillate. Anthers oblong-lanceolate, ca. 1 mm long, emarginate and sagittate; filaments ca. 0.5 mm long. Mature capsule not seen, but the ovary with marginal placentation and elongate funicles.

The growth habit of this species is somewhat unusual. From the limited material available one concludes that rosettes produce either scapes or rhizomal buds from older axillae. The rhizomes are elongate, zig-zag, and with short, evenly separated leaves. The offshoots frequently branch and ultimately produce new rosettes at the tips, the whole proliferating product presumably forming extensive clones. Mature seeds would be necessary to establish the relationship of this to others of the section *Xyris*.

Preliminary Checklist of the Vascular Plant Flora of Cerro Aracamuni

The checklist has been arranged into two groups: pteridophytes and seed plants. Within each group, families are arranged alphabetically and are divided up into the four main areas of collection in the following order: Summit, East Escarpment, Quebrada Camp, and Granitic Dome. Within each of the collecting areas, genus and species are listed alphabetically. Each species is followed by the name of the principal collector and number.

Details of the camp and collecting locations, along with a list of the co-collectors with their number ranges and dates of collection, are given below.

SUMMIT

The Dunsterville collections give the coordinates: 01°30′N Lat., 65°51′W Long., 1,510 m.

G.C.K. & E. Dunsterville s.n., Dec. 1972

Brewer Carias gives only elevation, 1,500 m.

Charles Brewer Carias s.n., 13 Dec. 1983

The 1987 expedition had two summit camps located at extreme ends of the massif: Popa Camp, situated at 01°26′N Lat., 65°47′W Long., 1,550 m, and Proa Camp, situated at 01°32′N Lat., 65°49′W Long., 1,400 m.

Carnevali & Santana 2362–2457, Popa Camp, 27–30 Oct. 1987
Carnevali & Liesner 2458–2584, Proa Camp, 30 Oct.–3 Nov. 1987
Liesner & Delascio 21934–22182, Popa Camp, 15–19 Oct. 1987
Liesner & Carnevali 22407–22730, Proa Camp, 25 Oct.–3 Nov. 1987

EAST ESCARPMENT

01°32′N Lat., 65°48′W Long., 750 m. Habitats here consisted of shrub thickets, exposed rock, and low dense forest.

Huber & Medina 5892–5942, 10 Feb. 1981

QUEBRADA CAMP

01°24′N Lat., 65°38′W Long., 500–600 m. Located along a stream slightly south and east of the summit in low open forest on a smooth, rocky outcrop near rapids.

Liesner & Delascio 22183–22270, 20–21 Oct. 1987
Liesner & Carnevali 22271–22406, 21–24 Oct. 1987

GRANITIC DOME

Collections from this site were made by Wurdack and Adderley from a 900-m granitic dome with low herbaceous vegetation on open rock and scrub forest. The dome is on the right side of Río Siapa, just below the rapids, Raudal Gallineta.

Wurdack & Adderley 43538-43572, 21 July 1959

Araceae—George S. Bunting

Summit:
Anthurium ptarianum Steyerm.—Liesner 22024, 22039, 22684
Philodendron callosum K. Krause subsp. *ptarianum* (Steyerm.) Bunting—Liesner 22672, 22720. Sterile and fertile specimens have slender, scandent stems and very small leaves.
Philodendron roraimae K. Krause subsp. *aracamuniense* Bunting—Liesner 22502, 22510, 21956
Philodendron tatei K. Krause subsp. *melanochlorum* (Bunting) Bunting Liesner 22178A, 22487, 22704. Described originally from collections from the Gran Sabana, similar material has subsequently been collected in Territorio Federal Amazonas, as well as some plants nearly intermediate between this and subsp. *tatei* that demonstrate the close relationship of these taxa. Four collections from Cerro Aracamuni appear to represent subsp. *melanochlorum*, which has a much narrower leaf blade than subsp. *tatei*. Of these, *Liesner & Delascio 22178A*, taken from an immature plant, has ovate leaf blades subcordate at base in contrast to the usually elliptic blades with obtuse or acute bases. The relevance of this variation is unknown.
Stenospermation cf. *nebulense* Bunting Liesner 22437. The type collection is from Cerro de la Neblina at 1,500 m.
Stenospermation ulei K. Krause—Liesner 22676

Quebrada camp:
Anthurium bonplandii Bunting subsp. *rionegrense* Bunting Liesner 22311
Heteropsis spruceana var. *robusta* Bunting Liesner 21926
Heteropsis spruceana Schott. var. *spruceana* Liesner 22832
Philodendron englerianum Steyerm. subsp. *duidae* (Steyerm.) Bunting—Liesner 22406
Philodendron maguirei Bunting—Liesner 22243. Known also from Cerro Arauicaua and Cerro de la Neblina.
Philodendron cf. *maroae* Bunting—Liesner 22332. The determination is in question because of the paucity of material and the lack of data concerning the petiole shape; until now *P. maroae* has been known only from lowland savanna near Maroa.
Schismatoglottis bolivariana Bunting & Steyerm. Liesner 22192. A rather rare species, this is apparently the first record outside of Estado Bolívar. The specimen is identical to other material except for the greater size of the leaf blade (45 cm long, 32.5 cm wide).
Stenospermation cf. *ulei* K. Krause—Liesner 22320. Specimen sterile but apparently pertaining to this widespread species with nodding inflorescence.

Arecaceae—Andrew Henderson (NY)

Dicranopygium imeriense Harling — Liesner 22309

Cyperaceae — Gerrit Davidse (MO)

Summit:
Didymiandrum stellatum (Boeckeler) Gilly — Liesner 22015
Rhynchocladium steyermarkii (T. Koyama) T. Koyama — Liesner 21941

Quebrada camp:
Calyptrocarya glomerulata (Brongn.) Urban — Liesner 22364
Cephalocarpus confertus Gilly — Liesner 22333
Hypolytrum pulchrum (Rudge) Pfeiffer — Liesner 22288
Mapania maguireana T. Koyama & Steyerm. ex T. Koyama — Liesner 22241
Mapaniopsis micrococca T. Koyama — Liesner 22193
Rhynchospora rigidifolia (Gilly) T. Koyama subsp. *planifolia* T. Koyama — Liesner 22224, 22227

Cyrillaceae — Julian Steyermark (MO)

Summit:
Cyrilla racemiflora L. — Carnevali 2365; Liesner 22073
Purdiaea nutans Planchon — Carnevali 2548; Liesner 22711

Dilleniaceae — Klaus Kubitzki (HBG); Ronald Liesner (MO)

East escarpment:
Doliocarpus savannarum Sandw. — Huber 5902

Quebrada camp:
Doliocarpus savannarum Sandw. — Liesner 22185, 22276

Dioscoreaceae

Summit:
Dioscorea spp. — Liesner 22415, 22436, 22484, 22541, 22710

Droseraceae — Bruce Holst (MO)

Summit:
Drosera roraimae (Klotzsch ex Diels) Maguire & Laundon — Liesner 22687, 22126

Quebrada camp:
Drosera roraimae (Klotzsch ex Diels) Maguire & Laundon — Liesner 22223

Elaeocarpaceae — Julian Steyermark (MO)

Summit:
Sloanea steyermarkii C. E. Smith subsp. *jauaensis* (Steyerm.) Steyerm. Sterile, but probably to be referred here. — Liesner & Carnevali 22722

Ericaceae — James Luteyn (NY)

Summit:
Cavendishia callista J. D. Smith, s.l. — Liesner 22536
Orthaea wurdackii Maguire, Steyerm. & Luteyn Liesner 22102, 22545. The two collections cited show an interesting transition from the type collection at Neblina with a short racemose inflorescence, to recent Neblina collections where the inflorescence is a very short raceme, to these Liesner (Aracamuni) collections where the flowers are essentially sessile to fasciculate, 1 4-flowered inflorescences. Otherwise they seem to be equal. The species is known previously from Cerro de la Neblina.
Satyria carnosiflora Lanj. — Liesner 22521
Sphyrospermum cordifolium Benth. — Liesner 21979, 22563, 22686
Thibaudia cupatensis H. E. Huber - Liesner 21946, 21946A, 22579

Quebrada camp:

Lauraceae—Henk van der Werff (MO)

Summit:
Aniba cinnamomiflora Allen—Liesner 21967, 22065. The type of this species is from Cerro Sipapo, Territorio Federal Amazonas. *Aniba cinnamomiflora* has also been reported from lowlands in Estados Apure, Aragua, and Táchira. Distribution and habit (a shrub or small tree from Cerro Sipapo and Aracamuni, large timber tree from the other localities) suggest that the collections outside Territorio Federal Amazonas do not belong in *Aniba cinnamomiflora*; additional collections are needed to solve this problem.
Endlicheria vinotincta Allen Liesner 22008 (♀), 22414 (♂), 22292 (♂). On the summit and slopes of Cerro Aracamuni, 600 1,500 m. Previously known from two collections from Cerro Neblina. *Liesner & Carnevali 22414* and *22292* are the first staminate collections of this species.
Licaria trinervis van der Werff Liesner 22161 (type), 22451 (paratype), 22714 (paratype)

Melastomataceae—John J. Wurdack (US)

Summit:
Clidemia tepuiensis Wurd.—Liesner 22070
Graffenrieda cf. *polymera* Gleason subsp. *neblinensis* Wurd.—Liesner 22423, 22699, 22730. The Aracamuni collections, mostly in young bud, differ from the Cerro Neblina subspecies by having lower leaf surfaces with very attenuated pubescence and very faint secondary nerves, obscure pedicels only 0.5–1 mm long, and smaller flowers (petals ca. 8 × 5.5 mm, anthers 3.5–4.5 mm long with basal spur 1–1.3 mm long). I am reluctant to describe a new subspecies until more material is available.
Macairea theresiae Cogn.—Liesner 21949. Otherwise known from lowland white sand savannas of the middle and lower Amazon and Rio Negro basins in Brazil, the closest locality being the Rio Araca (fide Renner Mss.).
Maieta neblinensis Wurd.—Liesner 22068, 22583. Otherwise known only from the upper slope forests of Cerro Neblina in Venezuela and Brazil, 650–1,300 m.
Miconia curta (Gleason) Wurd.—Liesner 22688
Miconia dodecandra (Desr.) Cogn.—Liesner 22166
Miconia roraimensis Ule—Liesner 22150, 22523, 22663
Neblinanthera cumbrensis Wurd.—Liesner 21937, 22657. Otherwise known from the upper slopes of Cerro Neblina in Venezuela and Brazil, 1,300–1,800 m.
Salpinga pusilla (Gleason) Wurd. Liesner 21986, 21987, 22063. Otherwise restricted to the summit and upper slopes of Duida and Neblina, often a quasi-rheophyte.
Tateanthus duidae Gleason—Liesner 22627
Tibouchina dissitiflora Wurd.—Liesner 22080
Tococa liesneri Wurd.—Liesner 22007 (paratype), 22700 (type)
Tococa pachystachya Wurd.—Liesner 21938. Otherwise known only from cloud forest of the upper slopes of Cerro Neblina, 1,450–2,000 m.

Sauvagesia guianensis (Eichler) Sastre subsp. *aracamuniensis* Steyerm.—Liesner 22075 (type)
Tyleria silvana Maguire—Liesner 22006. This species was originally described from the upper slopes of Serra Pirapucú, a sandstone table mountain in northern Brazil just south of and adjacent to the Brazilian side of Serra da Neblina. The collection of *Liesner & Delascio 22006* from the summit of Cerro Aracamuni at an altitude of 1,550 m marks the first report of this taxon from Venezuela. The Cerro Aracamuni specimens differ from typical *Tyleria silvana* by having fimbriate intermediate appendages between the staminodes 5.5 mm vs. 2.5 mm and primary bracts of the inflorescence 20–30 mm vs. 18–22 mm. The Venezuelan collection has the glandular-scarious apices of the sepals and bracts typical of *T. silvana* and agrees in all other characters.

East escarpment:
Sauvagesia falcisepala Sastre—Huber 5918 (type)

COMPOSITAE OF THE GUAYANA HIGHLAND—II. NOVELTIES IN *GONGYLOLEPIS* AND *STENOPADUS* (MUTISIEAE)[1]

John F. Pruski[2]

ABSTRACT

Described from the Guayana Highland are: *Gongylolepis oblanceolata* from Serra Aracá, Brazil, and from Sierra de Unturán and Cerro de la Neblina, Venezuela; *Stenopadus aracaënsis* from Serra Aracá, Brazil; and *Stenopadus megacephalus* from Mount Ayanganna, Guyana. The relationships of each new taxon are discussed and a key to species of both genera is given. *Stomatochaeta colveei* is transferred to *Stenopadus* and the combination *Stenopadus colveei* is proposed. Additionally, five species from the Guayana Highland are newly documented for the flora of Brazil.

The shrubby, homogamous, generally large-headed Mutisieae are a striking element of the Guayana Highland flora and are typically found on tepui summits. Among Guayanan taxa of its size—57 of the 61 currently recognized species (93%) are endemic to Guayana—the Mutisieae are unparalleled in their endemism level (Maguire, 1956; Pruski, 1989). The woody, hermaphroditic members of the tribe Mutisieae from Guayana fall into two main generic groups. The first group (subtribe Mutisiinae sensu Cabrera, 1977) consists of six genera having homogamous capitula composed of zygomorphic flowers and includes *Gongylolepis* Schomb., with one species described herein. The second group (subtribe Gochnatiinae sensu Cabrera, 1977) contains four genera, which have only actinomorphic flowers within their capitula. The second group was previously represented in Guayana only by *Quelchia* N. E. Brown and *Stenopadus* S. F. Blake, but has been redefined to admit two new genera, equivalent in part to species formerly placed in *Stenopadus* s.l. The newer genera are *Stomatochaeta* (S. F. Blake) Maguire & Wurdack (1957), which was raised from subgeneric level within *Stenopadus*, and *Chimantaea* Maguire et al. (1957), which was described as new. All subsequent authors (Aristeguieta, 1964, 1968; Steyermark, 1980, 1984; Pruski, 1989) have recognized *Stomatochaeta* and *Chimantaea*, the generic status of which is justified by floral morphology.

In this paper new species of *Gongylolepis* and *Stenopadus* are described preliminary to my treatment of the Compositae for the *Flora of the Venezuelan Guayana* by Julian Steyermark and collaborators, where the localities and complete synonymies of all our Mutisieae will be given. Also, fertile material of *Stomatochaeta colveei*, recently made available to me for study, shows that this species has the flower color and morphology typical of *Stenopadus*, to which it is herein transferred.

GONGYLOLEPIS

Gongylolepis is a genus of 15 species with bilabiate flowers and glabrous, reticulate, lanceolate to obovate leaves. Fourteen of these occur in the Guayana Highland and 11 are endemic to the Venezuelan Guayana. The nearest generic relative of *Gongylolepis* is the monotypic *Eurydochus* Maguire & Wurdack. The two genera have similar leaves and capitulescences, but *Eurydochus* differs

[1] I thank Rupert Barneby for help with the Latin diagnoses and for many helpful comments; Victor Badillo, Harold Robinson, and an anonymous reviewer for their suggestions; Bruno Manara for drawing Figure 2; Hans Beck, Otto Huber, and Iain Prance for permission to publish their photographs; and Don Black, María Lebrón-Luteyn, Marcia Stevens, and Muriel Weinerman for helping me prepare the figures. My herbarium studies in Venezuela have been financially supported by the Missouri Botanical Garden, *Flora of the Venezuelan Guayana* project.

FIGURE 1. *Gongylolepis oblanceolata*. —A. Note the nearly glabrous, minutely bracteolate peduncle and the occurrence of two capitula at the stem apex (*Prance et al. 29014*). Photo by G. T. Prance.—B. Note the larger, solitary capitulum, zygomorphic flowers, and the pubescent peduncle (*Henderson et al.* 961). Photo by H. Beck.

from *Gongylolepis* by deciduous (vs. persistent) pappus setae, by pubescent (vs. glabrous) phyllaries, and by pubescent (vs. glabrous) achenes. Less closely related to *Gongylolepis* are *Glossarion* Maguire & Wurdack and *Duidaea* S. F. Blake, which differ, respectively, in abaxially tomentose and one-nerved leaves. Described and keyed below is a new, predominantly monocephalous *Gongylolepis*. It is most closely related to the other pedunculate, monocephalous species of the genus, these mostly confined to T. F. Amazonas, Venezuela.

Gongylolepis oblanceolata Pruski, sp. nov. TYPE: Brazil. Amazonas: Platô da Serra Aracá, 200 km N de Barcelos, Mar. 1984, *M. G. Silva et al.* [co-collector names not given on type labels] *7169* (holotype, INPA; isotypes, K, MO, NY, US). Figures 1, 4.

Gongylolepidi bracteatae et *G. pedunculatae* affinis, quibuscum capitulis pedunculatis foliisque aut petiolatis aut basin versus angustatis congruit, sed a priori pedunculis ebracteatis et a secunda phyllariis magis numerosis et minoribus differt.

Branched shrubs 1–3 m tall; *stems* terete, striate, leafy and often lanate (especially in upper leaf axis) distally, glabrous and leafless proximally, internodes to ca. 1 cm long, thereby much shorter than the leaves. *Leaves* simple, alternate, often apically clustered, subsessile or petiolate; *blade* coriaceous, oblanceolate, ca. 5–21 × 1.5–4.5 cm, narrowly cuneate or attenuate basally, often narrowed into a subpetiolar base, apically acute, obtuse or rounded, margins entire, these not thickened, rarely revolute, venation pinnate, reticulate, upper blade surface dark green, often puberulent when young, especially so along midrib, glabrous with age, lower blade surface light green, often pubescent when young, glabrous with age; *petiole* often represented only by a petioliform leaf base to 5 mm long, clasping and stout. *Capitula* generally solitary, terminal, pedunculate, homogamous, with ca. 14–31 flowers, these perfect and fertile; *peduncle* often bracteolate, nearly glabrous to densely pubescent, ca. 3–8 cm long; *involucre* narrowly hemispheric, ca. 2.5–3.8 × 1.8–2.5(3) cm, 5–6-seriate; *phyllaries* ca. 25–30, imbricate, graduated, erect or

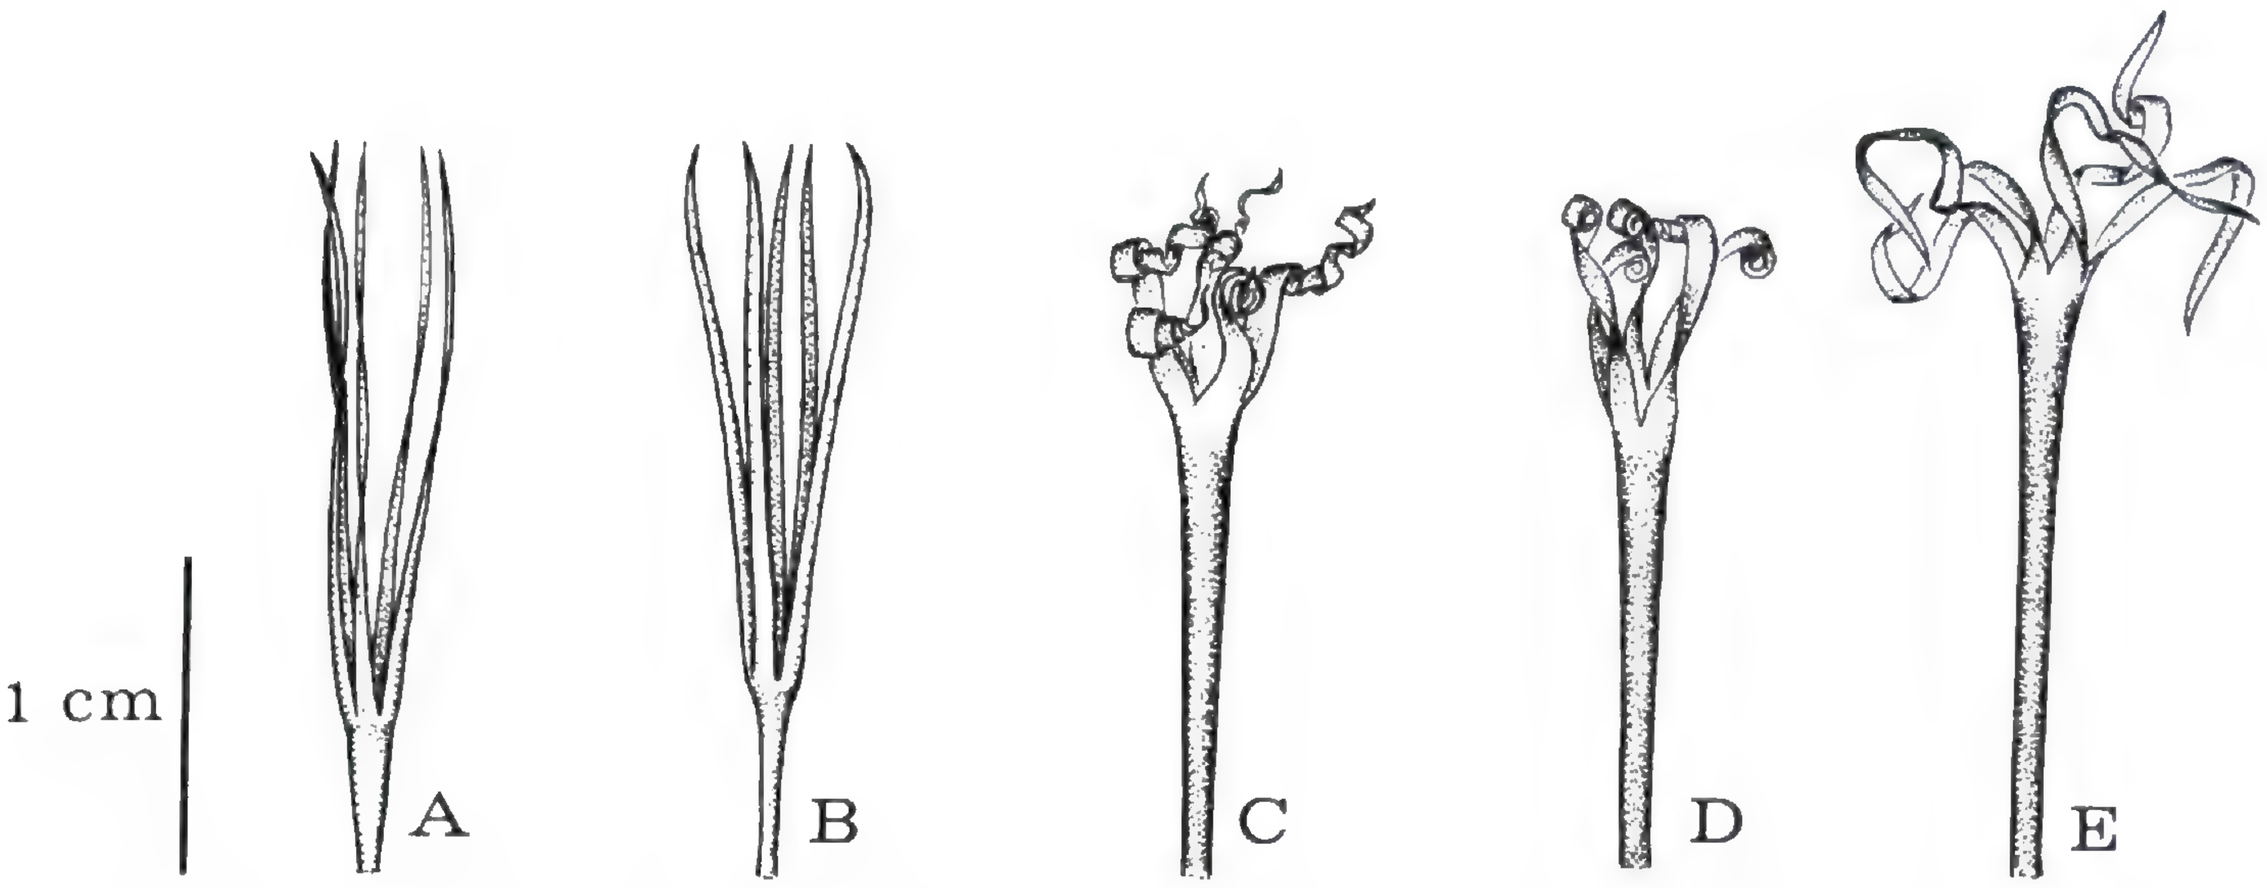

FIGURE 2. Corollas of representative species of *Stomatochaeta* and *Stenopadus*.—A. *Stomatochaeta condensata* (Baker) Maguire & Wurd. (Drawn from *Pruski & Steyermark 1454*, NY.)—B. *Stomatochaeta acuminata* Pruski. (Drawn from the holotype, *Huber 11374*, VEN.)—C. *Stenopadus chimantensis* Maguire, Steyerm. & Wurd. (Drawn from *Pruski & Huber 3616*, NY.)—D. *Stenopadus aracaënsis* Pruski. (Drawn from the holotype, *Prance et al. 29184*, INPA.)—E. *Stenopadus colveei* (Steyerm.) Pruski. (Drawn from *Huber 12405*, VEN.) Note in *Stomatochaeta* (A, B) the short corolla tube and the long, stiffly erect lobes. The corollas of *Stomatochaeta* are yellowish. Note in *Stenopadus* (C–E) the long corolla tube and the coiled or flexuous lobes as long as or shorter than the tube. The corollas of *Stenopadus* are magenta.

sometimes slightly spreading, thickly coriaceous, glabrous, entire, often somewhat purple; outer phyllaries triangular-ovate, ca. 2.5–6 × 2.5–5.5 mm, apex broadly acute to rounded, basally rounded or cordate, sometimes decurrent onto peduncle; inner phyllaries elliptic-lanceolate to lanceolate, to ca. 2.5 cm × 3.5 mm, apex commonly rounded; *receptacle* broadly dome-shaped, naked, aveolate, these pits 5- or 6-sided. *Corollas* bilabiate, 15–21(24) mm long, glabrous, reddish, or tube sometimes pale yellow; *tube* 9–14 mm long, narrow or with upper portion broadened near sinuses of the 2 lips, obscurely ca. 10-nerved; *lips* coiled; the outer, larger lip apically 3-dentate, to ca. 10–12 mm long when uncoiled, commonly coiled at apex or for more than half its length; the inner, lower lip 2-cleft, generally strongly coiled, thereby shorter than the outer lip; *anthers* exserted, linear, reddish, less commonly pale yellow, 10–12 mm long, apically acuminate, prominently sagittate basally; tails white, squamose, linear, 5–7 mm long, thereby more than half as long as the anthers, tails of adjacent anthers commonly completely connate or occasionally free basally; *filaments* yellowish or reddish, inserted well below bases of lobes; *styles* reddish above, yellowish below, branches spreading, ca. 1 mm long, apically obtuse. *Achenes* linear or slightly fusiform, ca. 10-costate, 10–11 mm long, brown, glabrous; *pappus setae* numerous, persistent, linear, brown, ca. 13–17 mm long, thereby longer than the achenes.

Distribution. Known from the plateau of Serra Aracá, Brazil, ridges of Sierra Unturán, Venezuela, and low elevation slopes and canyon walls of Cerro de la Neblina, Venezuela. This species has been collected from (400) 700–1,250 m and is known to flower and fruit from February to July.

Paratypes. BRAZIL. AMAZONAS: Município de Barcelos: platô da Serra Aracá, parte SE da Serra Norte, 0°51′N, 63°22′W, 1,150–1,250 m, 14 Feb. 1984, *I. L. Amaral 1557* (F, INPA, NY, US); plateau of northern massif of Serra Aracá, savanna, S side of north mountain, 0°51–57′N, 63°21–22′W, 1,200 m, 12 Feb. 1984, *G. T. Prance, I. L. Amaral, J. J. Pipoly, A. S. Tavares, M. G. Silva, C. D. A. Mota & A. Cress 29014* (INPA, K, NY, UC); platô da Serra Aracá, parte SE da Serra Norte, beira do rio mais próximo a pista, 0°51′N, 63°22′W, 1,150–1,250 m, 13 Feb. 1984, *A. S. Tavares, L. A. Cisneros & M. G. Silva 22* (INPA, NY). VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Dept. Río Negro, Neblina massif, Cañón Grande, along the Río Mawarinuma between the mouth of the canyon and the first major fork of the river, ca. 7 airline km ENE of Puerto Chimo, 0°50-51′N, 66°02 06′W, 400–700 m, 9–14 July 1984, *G. Davidse & J. Miller 27363* (MY); Dept. Río Negro, Neblina massif, S-facing slope at the mouth of Cañón Grande, N of Puerto Chimo, 0°50′N, 66°06′W, 500–700 m, 15 July 1984, *G. Davidse & J. Miller 27399* (VEN); Sierra de Unturán, ridge opposite camp, 01°33′N, 65°12′W, 1,150 m, 4 Feb. 1989, *A. Henderson, H. Beck, H. Scott & L. Leigh 961* (NY, VEN); Cerro de la Neblina, slope N of Río Mawarinuma, above Puerto Chimo, 0°50′N, 66°05′W, 500–700 m, 25 Apr. 1984, *B. Stein & A. Gentry 1686* (VEN).

Gongylolepis oblanceolata, most readily recognized by its minutely bracteolate peduncles, is

FIGURE 3. *Stenopadus colveei* showing a few-flowered, narrowly cylindric capitulum (*Huber 12405*). Photo by O. Huber.

closely related to *G. bracteata* and *G. pedunculata*. These three species are linked by having pedunculate heads and large leaves that are either petiolate or narrowed into a petioliform base. *Gongylolepis oblanceolata* differs from *G. bracteata* in apically nonbracteate (vs. bracteate) peduncles and from *G. pedunculata* in smaller, more numerous (vs. larger and fewer) involucral bracts. Other seemingly less closely related monocephalous species of *Gongylolepis* generally have sessile heads and smaller, sessile leaves.

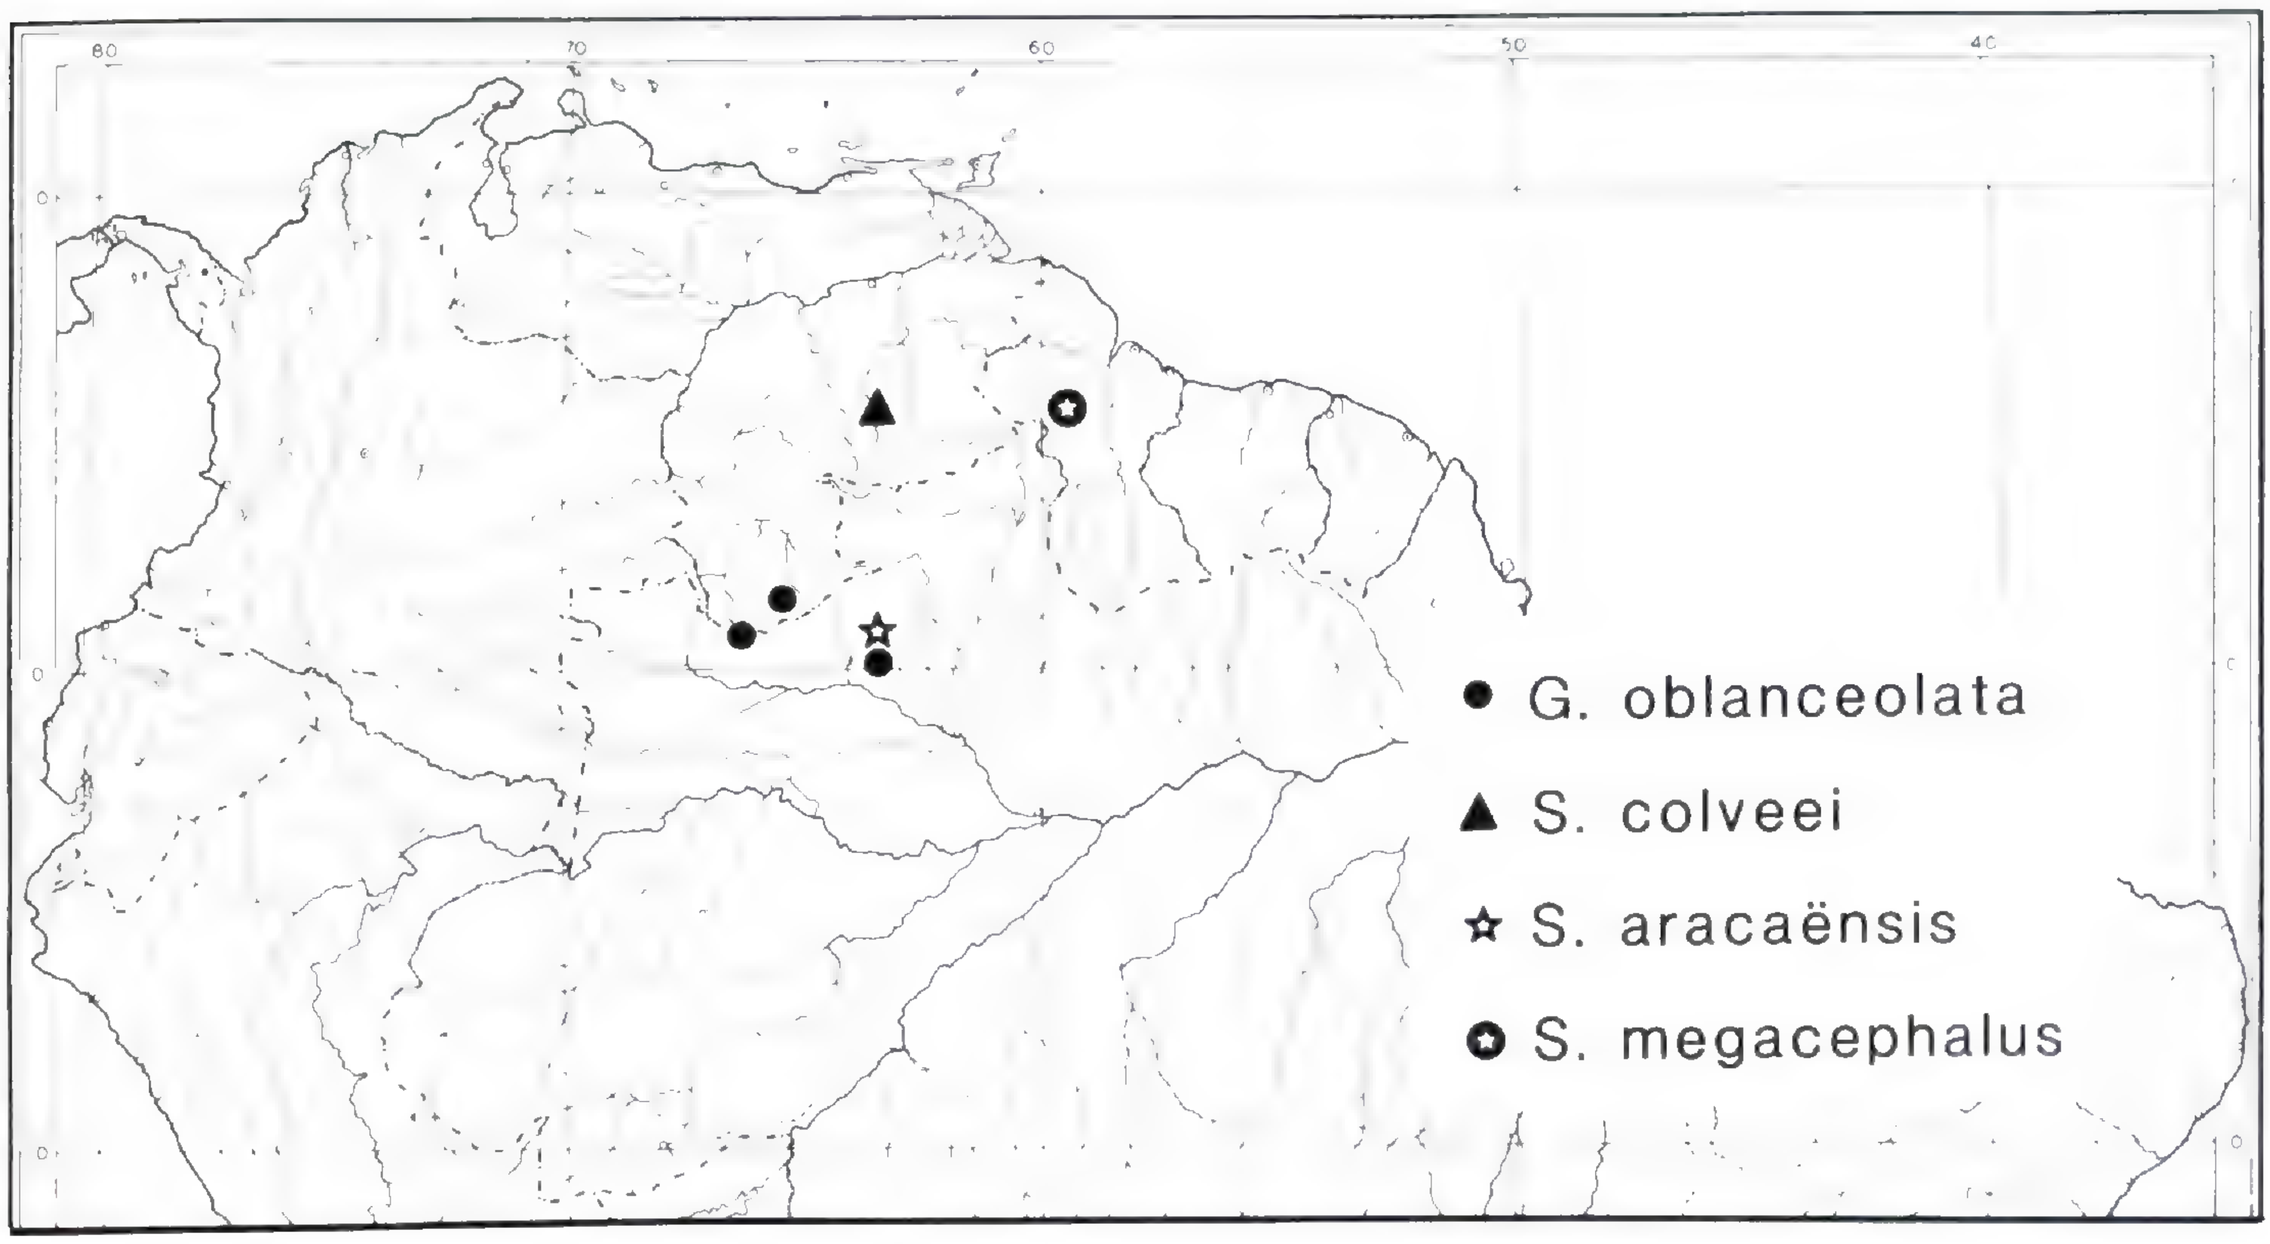

FIGURE 4. Distributions of *Gongylolepis oblanceolata*, *Stenopadus colveei*, *S. aracaënsis*, and *S. megacephalus*.

KEY TO THE SPECIES OF *GONGYLOLEPIS*

1a. Capitulescences monocephalous, rarely with two capitula per stem.
2a. Capitula stalked on a naked or leafy peduncle ca. 3 10 cm long.
3a. Leaves with subparallel venation, 8.5–15 × 3.3–6 cm, sessile; capitula ca. 60-flowered, ca. 5.5 cm tall ..... *G. jauaensis* (Aristeg., Maguire & Steyerm.) V. Badillo
3b. Leaves pinnately veined, 5–21(50) × (1.5)4–8.5 cm, sessile or petiolate; capitula 14–35-flowered.
4a. Capitula taller than 5 cm, outer and intermediate phyllaries ca. 1 cm or more wide; peduncles naked or leafy (bracteate); leaves (10)12–20(50) × 4–8.5 cm, basally cuneate, essentially sessile, wider than 5 mm at base.
5a. Peduncles leafy, capitula subtended by 1–3 large, leafy bracts; stem apex lightly pubescent ..... *G. bracteata* Maguire
5b. Peduncles naked, capitula not subtended by bracts; stem apex often densely pubescent to floccose ..... *G. pedunculata* Maguire
4b. Capitula shorter than 4.5 cm, phyllaries narrower than 8 mm; peduncles minutely bracteolate; leaves 5–21 × 1.5–4.5 cm, basally attenuate, subsessile or petiolate, narrower than 4 mm at base ..... *G. oblanceolata* Pruski
2b. Capitula sessile or on peduncles shorter than 2 cm, capitula ca. 8–15-flowered, shorter than 4 cm, outer and intermediate phyllaries narrower than 8 mm; leaves 3–10 cm long, sessile or petiolate.
6a. Subshrubs to 0.5 m tall, leaves often clustered at apex of naked spreading stems; leaves oblanceolate, sessile, ca. 3–7 × 0.7 2 cm wide and at least 3 times as long as wide ..... *G. fruticosa* Maguire, Steyerm. & Wurd.
6b. Shrubs or trees commonly 1.5 3(5) m tall, leaves not apically clustered; leaves elliptic to obovate, sessile to petiolate, ca. 2.5–10 × 1.2–5 cm, less than 2½ times long as wide.
7a. Leaves and branches glabrous; leaves obovate, sessile, to 10 × 4 cm ..... *G. glaberrima* S. F. Blake
7b. Young leaves and young branches pilose; leaves oblanceolate to broadly elliptic, subsessile to petiolate, less than 7 × 3 cm.
8a. Leaves with petioles ca. 5 mm long, secondary veins obviously pinnate; phyllaries obtuse to rounded at apex, wider than 5 mm ..... *G. paruana* Maguire
8b. Leaves subsessile or with petioles shorter than 3 mm, secondary veins subpalmate; phyllaries acute to acuminate, narrower than 5 mm ..... *G. erioclada* S. F. Blake
1b. Capitulescences branched, of few to many capitula, each of these pedunculate.
9a. Stems pubescent when young.
10a. Capitulescence leafy.
11a. Main stem leaves commonly (12)15 20 cm long; corollas glabrous ..... *G. yapacana* Maguire
11b. Leaves shorter than 13 cm; corollas hairy ..... *G. benthamiana* Schomb.

10b. Capitulescence naked, not leafy.
12a. Capitulescence umbelliform, peduncles 3–6 cm long; leaves thickly coriaceous, narrower than 3.5 cm, margins often thickened and revolute; stem apex often densely pubescent to floccose ..... *G. huachamacari* Maguire
12b. Capitulescence corymbiform, peduncles 1 3 cm long; leaves thinly coriaceous, 3–6 cm wide, margins slightly thickened, not revolute; stem apex generally lightly pubescent ..... *G. terramarae* Steyerm.
9b. Stems glabrous.
13a. Capitulescence naked, not leafy; leaves commonly petiolate, often prominently so.
14a. Leaves of flowering stems subsessile or with petioles to ca. 1 cm long; pappus straw-colored.
15a. Leaves subsessile; capitulescence corymbiform; plants of the Andes of Colombia and Venezuela ..... *G. colombiana* (Cuatrec.) Cuatrec.
15b. Leaves with petioles to ca. 1 cm long; capitulescence umbelliform or corymbiform; plants of Guayana, occurring 1,000–2,700 m ..... (return to couplets 12)
14b. Leaves of flowering stems with petioles 1–3 cm long; pappus straw-colored to rose-colored; plants generally occurring below 150(–750) m ..... *G. martiana* (Baker) Steyerm. & Cuatrec.
13b. Capitulescence leafy or sometimes naked when in fruit; leaves sessile or shortly petiolate.
16a. Capitulescence umbelliform ..... *G. huachamacari* Maguire
16b. Capitulescence corymbiform.
17a. Corollas hairy, tube broadened; leaves 7.5–16.5 × 2–5.5 cm, upper surface strongly reticulate; heads rounded at the base, involucre ca. 3 cm tall, ca. 6-seriate; achenes 6–13 mm long, mostly cylindric ..... *G. benthamiana* Schomb.
17b. Corollas glabrous, tube narrow; leaves 12–27 × (2.5) 5–8(9) cm, upper surface moderately reticulate; heads narrowed at the base, involucre ca. 3–3.5 cm tall, ca. 6 8-seriate; achenes 8–15 mm long, frequently fusiform ..... *G. paniculata* Maguire

Stenopadus

Described and keyed below are two new species of *Stenopadus* which, following the transfer of *Stomatochaeta colveei* to *Stenopadus*, raises to 14 the number of species recognized in this genus. All are endemic to the Guayana Highland and eight species are restricted to Venezuelan Guayana. *Stenopadus* is closely related to *Stomatochaeta*, which was originally described as a subgenus of *Stenopadus*. The yellowish corollas of *Stomatochaeta* (Fig. 2A, B) with stiffly erect lobes much longer than the tube distinguish it from *Stenopadus* (Fig. 2C–E), which has magenta corollas with (at maturity) coiled or flexuous lobes about as long as or shorter than the tube. By these features generic status for the two taxa is justified (Maguire & Wurdack, 1957; Pruski, 1989).

Stomatochaeta colveei resembles *Stenopadus* in a magenta corolla with tube longer than the lobes. It was originally (incorrectly) described and illustrated as having corolla lobes stiffly erect and was thus placed by Steyermark (1980) in *Stomatochaeta*. Pruski (1989) noted it as possibly intermediate between these two genera, but he retained it within *Stomatochaeta* until flowering material could be observed. Specimens examined by me during a recent visit to the Instituto Botánico in Caracas show that the corolla lobes of *Stomatochaeta colveei* are flexuous and shorter than the tube (Fig. 2E). Thus, this species fits well within *Stenopadus* as envisioned here, and the formal transfer of this species to *Stenopadus* is proposed below.

Stenopadus and *Stomatochaeta* now stand clearly apart from each other on the basis of flower morphology. Furthermore, *Stenopadus*, a genus of stately plants up to 25 m tall, is typically more robust than *Stomatochaeta*, plants of which are less than five m tall. Other genera from Guayana commonly with only actinomorphic flowers, and slightly less closely related to *Stenopadus* are *Chimantaea*, which has abaxially tomentose leaves and corolla lobes pilose when young, and *Quelchia*, which has small, uniflorous capitula.

Stenopadus colveei (Steyerm.) Pruski, comb. nov. *Stomatochaeta colveei* Steyerm., Brittonia 32: 21. 1980. TYPE: Venezuela. Bolívar: cumbre Cerro Guaiquinima, sector SE, cerca del borde, 5°40′N, 63°26′W, 1,250 m, 26 May 1978, *Steyermark, Berry, Dunsterville & Dunsterville 117407* (holotype, VEN). Figures 2E, 3, 4.

This species is a shrub 1.5–2.5 m tall characterized by basally attenuate, oblanceolate leaves and by narrowly cylindric, 5–6-flowered capitula. It is endemic to Cerro Guaiquinima, where it occurs in rocky or sparsely covered shrubby chaparral from 900–1,350 m and flowers in December and May.

Additional specimens examined. Venezuela. Bolívar: meseta del Guaiquinima, sector SE de la cumbre, 5°51′N, 63°25′W, 1,350 m, 26 Sep. 1985 (sterile), *Huber & Medina 10925* (VEN); cumbre de la meseta del Guaiquinima, sector S, a lo largo del Río Carapo, aprox. 8 km al N del Salto Carapo, 5°51′N, 63°33′W, 900 m, 6 Dec. 1987, *Huber 12405* (AAU n.v., HBG n.v., MY, NY, TFAV n.v., US n.v., VEN).

FIGURE 5. Holotype of *Stenopadus aracaënsis* (*Prance et al. 29184*, INPA).

Stenopadus aracaënsis Pruski, sp. nov. TYPE: Brazil. Amazonas: plateau of northern massif of Serra Aracá, N part of N slope, 0°51–57′N, 63°21–22′W, 1,400 m, 20 Feb. 1984, *G. T. Prance, I. L. Amaral et al. 29184* (holotype, INPA; isotypes, K, MO, NY, US). Figures 2D, 4, 5.

Stenopado kunhardtii affinis et cum illa corollae lobulis tubo multo brevioribus congruens, sed capitulis haud stipitatis ad maximum 25 (nec 35–70) flosculosis diversa.

Tress 10 m tall, 30 cm diam.; *stems* terete, striate, glabrous, leafy distally, leafless proximally, internodes to ca. 1.5 cm long, thereby shorter than the leaves. *Leaves* simple, alternate, often apically

FIGURE 6. Holotype of *Stenopadus megacephalus* (*Tillett et al. 45100*, NY).

clustered, petiolate; *blade* rigid-coriaceous, glabrous, broadly oblanceolate or obovate, ca. (4)6–13.5 × (1.5)2.5–4.7 cm, narrowly cuneate or attenuate basally, apically rounded, margins entire, thickened, somewhat revolute, venation pinnate, reticulate or third-order veins often obscure, upper blade surface dark green, lower blade surface pale green; *petiole* ca. 0.9–1.5 cm long, thin and nonclasping. *Capitula* solitary, terminal, sessile and thus nonstipitate, homogamous, with 21–25 flowers, these perfect and fertile; *involucre* cylindric, ca. 4.2–4.8 × 2–2.5 cm, 7–8-seriate; *phyllaries*

ca. 40–45, imbricate, graduated, tightly appressed and rigidly erect, coriaceous, glabrous, entire; outer phyllaries slightly carinulate, triangular-ovate, ca. 4–8 mm long and broad, apex broadly acute or obtuse, not decurrent onto stem; inner phyllaries elliptic-lanceolate to lanceolate, ca. 3 cm × 3.5–5 mm, apex commonly rounded; *receptacle* weakly paleaceous, paleae linear, ca. 2.5 cm long, cream-colored. *Corollas* actinomorphic, tubular, strongly 5-cleft, ca. 19–22 mm long, magenta, glabrous; *tube* 14–16.5 mm long, narrow and much longer than the lobes, weakly ca. 15-nerved; *lobes* either flexuous and only apically coiled or strongly coiled nearly to base, ca. 5–6 mm long, generally 3(–5)-nerved and with an obvious central nerve; *anthers* exserted, linear, cream-colored but prominently purple-spotted, 8.5–9 mm long, apically acuminate, basally sagittate; tails white, smooth, linear, 2.5–3 mm long, tails of adjacent anthers connate; *filaments* yellowish or reddish, inserted within the tube; *styles* obscurely branched, magenta, glabrous but asperulous apically, to 4 cm long. *Achenes* (immature) obconic, ca. 10-costate, ca. 6 mm long, olivaceous, glabrous; *pappus setae* numerous, linear, cream-colored, ca. 13–19 mm long, thereby longer than the achenes.

Distribution. Known only from the type collection made on the plateau of Serra Aracá, Brazil at 1,400 m. Flowers in February.

Stenopadus aracaënsis, collected on a recent Projeto Flora Amazônica expedition, is most closely related to *S. kunhardtii*. Both species have three-nerved corolla lobes that are much shorter than the corolla tube and thereby closely resemble one another. However, *S. aracaënsis* clearly differs from *S. kunhardtii* by nonstipitate (vs. stipitate) heads, smaller basally attenuate (vs. larger basally cuneate) leaves, and capitula that contain 25 or fewer (vs. 35–70) flowers. Also closely related is *S. huachamacari*, but this differs from the two former species by two-nerved (vs. three-nerved) corolla lobes that are about as long as (vs. much shorter than) the corolla tube.

Stenopadus megacephalus Pruski, sp. nov. TYPE: Guyana: upper Mazaruni River basin, Mount Ayanganna, shoulder of E flank, above Thompson Camp, 1,418–1,585 m, 11 Aug. 1960, *S. S. Tillett, C. L. Tillett & R. Boyan 45100* (holotype, NY). Figures 4, 6.

Affinis *S. sericeo*, etiam in monte Ayanganna obvio, sed foliis subsessilibus et glaberrimis (nec petiolatis et infra sericeis) abstans.

Shrubs 2 m tall; *stems* terete, nonstriate, thick, glabrous, leafy distally, leafless proximally, internodes to ca. 1.5 cm long, thereby shorter than the leaves. *Leaves* simple, alternate, clustered toward end of branches, subsessile; *blade* rigidly and thickly coriaceous, glabrous, oblanceolate or obovate, 8.5–19 × 3–8.5 cm, cuneate basally and mostly narrowed into a petiolariform base, apically rounded, margins entire, thickened, slightly revolute, venation pinnate, obscurely reticulate with third-order veins often immersed, upper blade surface dark green, lower blade surface lighter green; *petioliform base* stout, ca. 5 mm long and broad, not clasping the stem. *Capitula* (well past maturity with flower parts mostly fragmentary) solitary, terminal, sessile or very shortly pedunculate, homogamous, with many (ca. 40 or more) flowers, these perfect and fertile; *involucre* hemispheric, ca. 5 × 4.5 cm, ca. 5-seriate; *phyllaries* ca. 40, imbricate, graduated, erect, coriaceous, glabrous, entire; outer phyllaries broadly triangular-ovate, ca. 1.4–1.8 × 1.3–1.5 cm, apex broadly acute or obtuse; inner phyllaries lanceolate, ca. 4.5 cm × 5–7 mm, apex acuminate to rounded; *receptacle* seemingly naked. *Corollas* actinomorphic, tubular, strongly 5-cleft, ca. 13 mm long, magenta, glabrous or weakly puberulent internally near sinuses of lobes; *tube* ca. 8–10 mm long, broadened near sinuses of lobes, weakly ca. 10-nerved; *lobes* sometimes flexuous but more commonly strongly coiled nearly to base, ca. 2–6 mm long, seemingly 2-nerved; *anthers* partly exserted, linear, cream-colored, ca. 13 mm long, apically acuminate, basally sagittate; tails cream-colored, smooth, linear, ca. 3–4 mm long, those of adjacent anthers apparently appressed but not connate; *filaments* mostly disintegrated, seemingly inserted within the corolla tube; *styles* not seen. *Achenes* broadly obconic, with ca. 4 or 5 main angles, ca. 5.5 × 2.5 mm, light brown, glabrous; *pappus setae* numerous, linear, light brown, tips mostly broken off, but intact setae to 15 mm long, thereby much longer than the achenes.

Distribution. Known only from the holotype, collected on Mount Ayanganna, Guyana, where the new species is frequent in dense scrubland between 1,418 and 1,585 m. Known to be in fruit in August.

Stenopadus megacephalus is closely related to *S. sericeus*, the only other species of *Stenopadus* reported from Mount Ayanganna. However, the leaves of *S. sericeus* are clearly petiolate and are sericeous below, whereas those of *S. megacephalus* are subsessile and completely glabrous. Also closely

related are *S. chimantensis*, which has wider leaves and smaller heads, and the distantly disjunct *S. campestris*, which has flexuous three-nerved (vs. strongly coiled two-nerved) corolla lobes.

KEY TO THE SPECIES OF *STENOPADUS*

1a. Anther filaments attached to corolla tube 1–4(10) mm below base of lobes.
  2a. Leaves subsessile or brevipetiolate with petioles shorter than 7 mm.
    3a. Leaves shorter than 11 cm; capitula with up to 25 florets; involucres shorter than 3 cm; corolla lobes 3-nerved ..... *S. campestris* Maguire & Wurd.
    3b. Leaves to 19 cm long; capitula with more than 30 florets; involucres 4–5 cm tall; corolla lobes 2-nerved ..... *S. megacephalus* Pruski
  2b. Leaves with petioles 8–20(35) mm long.
    4a. Outer phyllaries acuminate, inner ones attenuate; capitula often 2–4 per branch ..... *S. obconicus* Maguire & Wurd.
    4b. Outer phyllaries obtuse to acute, inner ones usually acute or obtuse, never attenuate; capitula solitary.
      5a. Corolla lobes 2-nerved, about as long as the tube ..... *S. huachamacari* Maguire
      5b. Corolla lobes 3-nerved, about 2½ to 3 times shorter than the tube.
        6a. Phyllaries not decurrent, involucre cylindric; leaves 6–13.5 cm long, basally attenuate; capitula with up to 25 flowers; corollas ca. 19–22 mm long; anthers (including tails) ca. 11–12 mm long, tails of adjacent anthers connate ..... *S. aracaënsis* Pruski
        6b. Outer phyllaries decurrent onto peduncle, the heads thereby stipitate and the involucres campanulate; leaves 9–21 cm long, basally cuneate to narrowly so; capitula 35–70-flowered; corollas (20)28–35 mm long; anthers (including tails) (12)15–16 mm long, tails of adjacent anthers connate, but easily separable ..... *S. kunhardtii* Maguire
1b. Anther filaments attached to corolla tube at the sinuses of the lobes.
  7a. Mature leaves sericeous below ..... *S. sericeus* Maguire & Aristeg.
  7b. Mature leaves glabrous or puberulent below.
    8a. Capitula narrowly cylindric, 5–6-flowered; leaves narrower than 2.3 cm ..... *S. colveei* (Steyerm.) Pruski
    8b. Capitula cylindric to hemispheric, ca. 12–100-flowered; leaves wider than 3 cm.
      9a. Outer phyllaries keeled, shiny ..... *S. connellii* (N. E. Brown) S. F. Blake
      9b. Outer phyllaries not keeled, not shiny.
        10a. Leaves to 35 cm long ..... *S. colombianus* Cuatrec. & Steyerm.
        10b. Leaves shorter than 26 cm.
          11a. Outer phyllaries ca. 1–2 cm long, elliptic-lanceolate, apically obtuse to rounded ..... *S. cucullatus* Maguire & Wurd.
          11b. Outer phyllaries shorter than 1 cm, triangular, apically acute.
            12a. Leaves shorter than 6 cm, rotund with rounded bases and apices ..... *S. jauaensis* Aristeg.
            12b. Leaves commonly longer than 6 cm, elliptic to ovate with attenuate to obtuse bases and apices.
              13a. Leaves subsessile, basally cuneate to obtuse; petioles shorter than 7 mm; young leaves sometimes sericeous ..... *S. chimantensis* Maguire, Steyerm. & Wurd.
              13b. Leaves petiolate, basally attenuate to narrowly acute; petioles ca. 1–2.5 cm long; leaves glabrous or puberulent, never sericeous ..... *S. talaumifolius* S. F. Blake

Known previously only from the Guayana Highland of Guyana and/or Venezuela, the following species are here recorded for Brazil, mostly from Serra Aracá:

Calea abelioides S. F. Blake (*Prance et al. 9810, 9876, 21555*; *Tavares et al. 141*). The first three collections cited above were reported from Brazil by Huber et al. (1984) as *C. cardonae* var. [subsp. in protologue] *neblinensis* Maguire & Wurd., a taxon not known to occur in Brazil.

Calea lucidivenia Gleason & S. F. Blake (*Amaral 1628*; *Prance et al. 28975*; *Prance & Guedes 29600*; *Rosa & Lira 2250*; *Tavares & Silva 36*).

Eupatorium (*Guayania*) *bulbosum* Aristeg. (*Pipoly et al. 6664*; originally determined as *Guayania* by H. Robinson). King & Robinson (1987, p. 412) listed it as restricted to Venezuela.

Eupatorium (*Chromolaena*) *pharcidodes* B. L. Robinson (*Prance et al. 29185*; *Rosa & Lira 2341*). This species is not reported from Brazil on p. 387 of King & Robinson (1987).

Mikania lucida S. F. Blake (*Amaral 1578, 1619*; *Prance et al. 20058, 29021*; *Tavares & Silva 63*; *Tavares et al. 120*). The provisional determination of *M.* cf. *lucida* based on *Prance et al. 20058* from near Auaris, Brazil and reported on p. 123 of Huber et al. (1984) is herein confirmed. King & Robinson (1987, p. 425) listed it as restricted to Venezuela.

CHROMOSOME NUMBERS IN COMPOSITAE, XVI: EUPATORIEAE II[1]

Harold Robinson,[2] *A. Michael Powell,*[3] *Gerald D. Carr,*[4] *Robert M. King,*[2] *and James F. Weedin*[5]

ABSTRACT

An additional 159 chromosome reports are provided for the tribe Eupatorieae with 13 new generic and 60 new species reports. Numbers now known include 94 of the 180 genera and over 450 of the more than 2,000 species. A primary base of $x = 10$ is confirmed for most of the subtribes, including the Adenostemmatinae (with first report of *Sciadocephala*), Eupatoriinae, Gyptidinae, most of the Ageratinae and Alomiinae, Liatrinae (with first report of *Hartwrightia*), Fleischmanniinae, Critoniinae, and Praxelinae. The occurrence of $n = 9$ is consistent for four additional species in *Acritopappus* of the Ageratinae, independent of that base number in the *Brickellia* group of the Alomiinae. Numerous reports are added for the Central American polyploid complex in *Fleischmannia*. Consistent higher base numbers of $x = 16$ 25 are found in new reports for the subtribes Neomirandeinae, Mikaniinae, and Oxylobinae. Numbers of $n =$ ca. 20–26 are noted in two species of *Kaunea* of the Oxylobinae with correction of one previous lower count erroneously credited to *K. lasiophthalma*. Distribution of the two bases, $x = 10$ and 16, in the Hebecliniinae are cited and problems in *Bartlettina* and the Critoniine genus *Eupatoriastrum* are discussed.

This paper continues a series dealing with chromosome numbers of Compositae (Raven et al., 1960; Raven & Kyhos, 1961; Ornduff et al., 1963, 1967; Payne et al., 1964; Solbrig et al., 1964, 1969, 1972; Anderson et al., 1974; Powell et al., 1974, 1975; King et al., 1976; Tomb et al., 1978; Robinson et al., 1981, 1985) and is the second dealing with the tribe Eupatorieae (King et al., 1976). New reports are provided for 13 genera and 59 species (marked by ** and * respectively in Appendix).

The new reports in this paper are based primarily on material collected by R. M. King and counted by A. M. Powell and J. F. Weedin (not coded) and G. D. Carr (C). The chromosome counts have been made from aceto-carmine or aceto-orcein squashes of microsporocytes in meiosis. Voucher specimens of the King collections are in US and a second set is in MO.

The previous paper in the series dealing with the Eupatorieae summarized the numbers then known from 327 of the approximately 2,000 species and 70 of the 180 genera now known in the tribe. The chromosome data were summarized again with few additions in the survey of the tribe by King & Robinson (1987). Studies subsequent to that of King et al. (1976) have added reports of ten additional genera: *Urolepis* $n = 10$ (Turner et al., 1979; Waisman & Rozenblum, 1986); *Hatschbachiella* $n = 10$ (Waisman & Rozenblum, 1986); *Lorentzianthus* $n = 10$ (Bernardello, 1986); *Alomia* $n = 10$ (Mabry et al., 1981; Baker & Turner, 1986; Sundberg et al., 1986); *Amolinia* $n = 10$ (Strother, 1983); *Flyriella* $n = 10$ (Baker & Turner, 1986; Sundberg et al., 1986); *Erythradenia* $n = 16$, *Eupatoriastrum* $n = 16$; *Kyrsteniopsis* $n = 10$; and *Piptothrix* $n =$ ca. 17 (Sundberg et al., 1986).

The present paper adds chromosome counts for the 13 additional genera: *Bahianthus* $n = 10$; *Bejaranoa* $n = 10$; *Bishovia* $n =$ ca. 10; *Cronquistianthus* $n =$ ca. 10; *Fleischmanniopsis* $n = 10$; *Goyazianthus* $n = 20$; *Platypodanthera* $n = 10$; *Pseudokyrsteniopsis* $n = 10$; *Sciadocephala*

[1] We thank Dr. Richard Wunderlin of the University of South Florida for collecting buds of *Hartwrightia* and Dr. Caloway Dodson of the Missouri Botanical Garden for collecting buds of *Sciadocephala*. We also thank Susan Richardson of the Smithsonian Institution for growing specimens from seed. Part of the work was supported by National Science Foundation grant #DEB 77-13457 to R. M. King.

$n = 10$; and *Trichogonia* $n = 10$. The new counts of $n =$ ca. 20 and ca. 26 for *Kaunea* seem to be the first reasonably representative figures for the genus. Chromosome numbers are now known from 94 of the 180 genera.

A few previously reported numbers are based on vouchers needing corrections of identification. The name *Ageratina aschenborniana* (Schauer) K. & R. used in earlier papers is a synonym of *A. bustamenta*, and *Ophryosporus origanoides* [Meyen & Walp.] Hieron. is a synonym of *O. heptanthus*. The plant reported by Coleman (1968: 235, Brazil: *Coleman 295*) as *Ageratum conyzoides* L. is *Barrosoa betoniciforme* (DC.) K. & R.

The general pattern of chromosome numbers in the tribe was first presented in King et al. (1976). Thirteen of the 18 subtribes had a base of $x = 10$ or clearly derived numbers, such as $x = 15$. The remaining five subtribes show higher base numbers with no remnant of $x = 10$. As elaborated from the chart in King & Robinson (1987), the subtribes have the following numbers with primary bases in **boldface**: Adenostemmatinae 5, **10**; Eupatoriinae **10**, 15, 20; Disynaphiinae **10**; Gyptidinae **10**; Ageratinae **9** (*Acritopappus*), **10**, **11**, **12** (*Microspermum–Piqueria–Stevia* group), 15, 20, 25; Trichocoroninae **15**; Ayapaninae **10**; Alomiinae **9** (*Brickellia* group), **10**; Liatrinae **10**, 20, 30; Fleischmanniinae 4 (*Fleischmannia microstemon*), **10**, 20, 30; Critoniinae **10**, 20; Praxelinae **10**, 20, 29; Hebecliniinae **10**, **16**; Neomirandeinae **17**, 20, 24, 25; Mikaniinae 16, **17**, 18, **19**, 20; Oxylobinae **16**, **17**, ca. 20, 51; Hofmeisteriinae **18**, **19**; Oaxacaniinae **18**. The pattern has not been altered by any of the more recent reports, and it is actually greatly reinforced by numerous new chromosome counts in the subtribes Ageratinae, Fleischmanninae, Hebecliniinae, and Oxylobinae. The only questionable additions since 1977 are in the Critoniinae and Hebecliniinae. Questionable counts have often been overturned by subsequent examination of vouchers, as in the case discussed under *Kaunea* in the Oxylobinae, or by reexamination of the species. The patterns seem well established, and deviations should be carefully rechecked.

The significant new reports are best reviewed in the order of the subtribes established in King & Robinson (1987).

Adenostemmatinae

The new report of $n = 10$ for *Sciadocephala* is the first for that genus and the first in the subtribe outside of *Adenostemma*. Evidently both genera retain the basic number of the tribe. There has been no further evidence in the subtribe for the low $n = 5$ reported by Turner & Irwin (1960) from a plant now determined as *A. involucratum*. Our new report for that species is $n = 10$. The two genera of the subtribe with the anomalous knob-formed pappus have now been counted, but the remaining genus *Gymnocoronis*, which lacks such a pappus, is still unstudied.

Eupatoriinae

The Waisman & Rozenblum (1986) count for *Hatschbachiella* completes the survey of genera in the subtribe. All four genera show a base of $x = 10$, with *Eupatorium* (including *Eupatoriadelphus*) showing some triploids and tetraploids.

Gyptidinae

The new generic reports for *Bahianthus*, *Bejaranoa*, *Litothamnus*, *Platypodanthera*, and *Trichogonia*, and the *Urolepis* counts (Turner et al., 1979; Waisman & Rozenblum, 1986) show that $n = 10$ is basic to the subtribe. The recent cytological study of *Gyptis pinnatifida* Cass. (as *Eupatorium tanacetifolium* Gillies ex Hook. & Arn. by Rozenblum et al., 1988) confirms the triploid condition based on $n = 10$ that is already known to occur in that genus and examines details of the apomixis in the species.

Ageratinae

The many new counts of *Acritopappus*, based on four species, strongly confirm the occurrence of $n = 9$ first noted for one of the species by Coleman (1970) and mentioned by King et al. (1976). The isolated occurrence of $n = 9$ in *Acritopappus* is apparently consistent for the genus, with reports from both viscid-leaved and non-viscid-leaved members. Prior to the discovery of $n = 9$ in *Acritopappus*, the number was known in the tribe from only *Brickellia* and its close relatives in the subtribe Alomiinae.

Other reports of chromosome numbers of Ageratinae since King et al. (1976) confirmed other known patterns. New counts of *Ageratum* spp. show a base of 10. The Dillon & Turner (1982) report of ca. $n = 10$ for *Ascidiogyne sanchez-vegae* Cabrera conforms with the $n = 10$ already known for the type species *A. wurdackii* Cuatr. This further indicates the difference between the latter genus and the members of the *Piqueria* relationship. New reports from *Piqueria* and *Stevia* and the Strother (1983) and Sundberg et al. (1986)

reports for *Microspermum debile* Benth. and *M. nummulariifolium* Lagasca conform to the already known bases of $n = 12$ and $n = 11$ in that group. The South American species reported for *Stevia* all have $n = 11$, and none show the $n = 12$ found in shrubby members of the genus in Central America.

ALOMIINAE

The new generic counts for *Goyazianthus*, *Planaltoa*, and *Pseudokyrsteniopsis*; generic counts by others for *Alomia*, *Flyriella* (Baker & Turner, 1986; Sundberg et al., 1986) and *Kyrsteniopsis* (Sundberg et al., 1986); and the counts for all three species of *Carminatia* (Turner, 1988) extend our knowledge of elements of the subtribe having the base number of 10. The Turner report for his new species, *Carminatia anomala*, is here attributed to the earlier name for the species, *C. alvarezii* Rzed. & Calderón de Rzedowski (1987). Chromosome numbers of the genera could all be anticipated on the basis of their evident relationships within the subtribe. The number $n = 9$ that is notably present in the Alomiinae in *Brickellia* (King et al., 1976; Keil et al., 1988), *Barroetea* (Sundberg et al., 1986), *Pleurocoronis*, and their immediate relatives is unknown in any of the primarily South American genera of the subtribe.

LIATRINAE

The new chromosome count for *Hartwrightia* completes the survey of the six genera of this small subtribe from the southeastern United States. All members of the subtribe have $n = 10$ or polyploids of that number.

FLEISCHMANNIINAE

The numerous new reports for *Fleischmannia* firmly establish $n = 10$ as the base for most of the species. No further examples have been found of the $n = 4$ that is characteristic of the weedy annual *F. microstemon* (Cass.) K. & R. and that has been reported for *F. hymenophyllum* by Grashoff et al. (1972).

The counts reported in the present study formed the basis for statements regarding the polyploid complex first noted by King & Robinson (1978, 1987) in Central America. The geographically restricted Guatemalan species *Fleischmannia bohlmanniana* K. & R., *F. deborabellae* K. & R., and *F. viscidipes* (B. L. Robins.) K. & R. prove to be diploid, while the more widely distributed weedy species *F. pratensis* (Klatt) K. & R. and *F. pycnocephala* (Less.) K. & R. continue to show a consistently polyploid condition.

CRITONIINAE

The three new generic reports for the subtribe (*Bishovia* K. & R., *Cronquistianthus* K. & R., and *Fleischmanniopsis*) and the *Lorentzianthus* count of Bernardello (1986) show the base of $n = 10$ that is characteristic of all previously known members of the group. The only serious suggestion of another base in the subtribe seems to involve the presently uncounted genus *Eupatoriastrum*, which is noted for its paleaceous receptacles. The species belonging to this genus have been associated with a similarly paleaceous species, *Eupatorium corvi* McVaugh (McVaugh, 1972) of Chiapas, which has an $n = 16$ (King et al., 1976). The latter is now recognized as the genus *Matudina* of the subtribe Hebecliniinae, and shows no detailed structural evidence of immediate relationship to *Eupatoriastrum*. In contrast, structural features of *Eupatoriastrum* suggest close relationship to *Koanophyllon*, which has numerous reports of a base of $n = 10$ in this study and in previous studies based on Central and South American material (King et al., 1976; Keil et al., 1988).

Therefore, it is surprising to see a report of $n = 16$ from *Eupatoriastrum nelsonii* Greenman (Sundberg et al., 1986). The voucher cited by Sundberg et al. from Coatepec, Veracruz (*Hernández 320*) has been sought for study, but the specimen is not deposited at TEX as indicated. The actual repository, XAL, has not replied. A specimen of *E. nelsonii* (*Hernández 355* TEX), collected from the same place, is correctly determined. The latter is the voucher for the chemical study by Bohlmann et al. (1985). It is possible that the $n = 16$ reported from *Eupatoriastrum nelsonii* is correct, and that the genus is a member of the Hebecliniinae rather than the Critoniinae. No characteristic of the genus precludes this. In fact, the form and texture of the corollas of *Eupatoriastrum* are rather like that of various members of the *Hebeclinium* group. Structural details indicate that placement within the Hebecliniinae, if correct, would be closer to *Decachaeta* than *Matudina*. Although the structural characters of the Hebecliniinae are less definite than those of most subtribes, there is no reason to believe that $n = 16$ has arisen more than once from $x = 10$.

King et al. (1976) placed *Peteravenia* in the *Hebeclinium* group and reported chromosome numbers of $n = 10$ and $n =$ ca. 17. The genus was transferred to the Critoniinae in King & Rob-

inson (1987), where the report of n = ca. 17 was rejected from the genus as the voucher proved to be *Ageratina subinclusa* (Klatt) K. & R. Two new counts further establish $n = 10$ as the base number for *Peteravenia*.

Praxelinae

New reports for *Chromolaena* and *Praxelis* (Appendix) and reports in recent literature (Sundberg et al., 1986) show the trend already known for high chromosome numbers and irregular meiosis in the subtribe.

Hebecliniinae

King et al. (1976) noted the *Hebeclinium* group for the presence of two distinct base numbers, $x = 10$ and $x = 16$. The members of the subtribe with $n = 10$ were *Hebeclinium* and the South American species of *Bartlettina*. In contrast, the Central American genera *Erythradenia* (Sundberg et al., 1986), *Decachaeta*, and *Matudina*, and the Central American species of *Bartlettina* showed $n = 16$. The geographical pattern seemed to be mostly South America versus Central America, with *Hebeclinium* being basically South American. Subsequent reports have generally confirmed the pattern. Strother (1983) reported $n = 16$ for four Central American species, *Bartlettina breedlovei* K. & R., *B. pansamalensis* (B. L. Robins.) K. & R., *B. pinabetensis* (B. L. Robins.) K. & R., and *B. tuerckheimii* (Klatt) K. & R., and the same number was reported by Sundberg et al. (1986) for *B. hintonii* K. & R. In an apparent exception to the characteristic $n = 16$, two Central American species of *Bartlettina tamaulipanum* (B. Turner) K. & R. and *Eupatorium xalapanum* B. Turner (= *B. brevipetiolata* (Schultz-Bip. ex Klatt) K. & R.) have been reported as $n = 10$ (Turner, 1985). The types have been seen, and they are clearly members of the Central American complex in the genus. The reports of $n = 10$ are greatly in need of confirmation.

The only basically Central American element of the Hebecliniinae presently known with $n = 10$ seems to be *Amolinia heydeana* (B. L. Robins.) K. & R. reported by Strother (1983).

Neomirandeinae

New reports for this monogeneric tribe include one species of each subgenus of *Neomirandea*. The reports of $n = 17$ for *N. eximia* agree with earlier counts. The reports of n = ca. 26 for *N. angularis* are the first of that number in the genus, but they offer limited consistency in a member of the typical subgenus of *Neomirandea*, which has previously been reported variously as $n = 20$, n = ca. 24, n = ca. 25 (King et al., 1976), and the species has recently been reported as $n = 25$ by Sundberg et al. (1986).

Oxylobinae

Reports since King et al. (1976) have provided an expected count of n = ca. 17 for *Piptothrix* (Sundberg et al., 1986) and supported previously known chromosome patterns of $n = 16$ for *Oxylobus* (Turner & Kerr, 1985) and $n = 17$ in *Ageratina* subgenera *Ageratina*, *Neogreenella*, and *Klattiella* (Jansen et al., 1984; Sundberg et al., 1986). Strother (1983) noted a minor departure of $n = 18$ for *Eupatorium subpenninervium* (= *Ageratina subinclusa* (Klatt) K. & R. The present study, Jansen et al. (1984), and Waisman & Rozenblum, (1986) give further examples of the subgenus *Andinia*, i.e., *Ageratina ampla* (Benth.) K. & R., *A. dendroides*, *A. pseudochilca*, *A. popayanensis* (Hieron.) K. & R., *A. angustifolia* (H. B. K.) K. & R., *A. arbutifolia* (Benth.) K. & R., *A. baccharoides* (H. B. K.) K. & R., and *A. elegans* (H. B. K.) K. & R. The counts confirm the consistent n = ca. 40 and n = ca. 42 already seen by King et al. (1976) in the subgenus except for the higher polyploid n = ca. 90 count for *A. angustifolia* by Waisman & Rozenblum (1986).

The new count of n = ca. 20 for *Kaunea ignorata* seems to reinforce the generally high number $2n$ = near 45 found by Royce Oliver in root tips of that species (King & Robinson, 1980). The new report of n = ca. 26 for *Kaunea lasiophthalma* conflicts with an earlier report of $n = 10$ for *Eupatorium lasiophthalmum* Griseb. (Turner et al., 1979), but the voucher for the latter report has been examined and proves to be *Lorentzianthus viscidus*, a species known to have an $n = 10$. It seems that *Kaunea* characteristically has a chromosome number at the level of n = 20–26, which is consistent with higher numbers in other known members of subtribe Oxylobinae. The higher numbers in *Kaunea* are reminiscent of those of another Andean member of the subtribe, *Ageratina* subg. *Andinia*. Nevertheless, the numbers in the two groups do not seem to be the same, and if other aspects of the plants are any indication of relationship, the higher numbers evidently originated separately. Structurally, *Kaunea* seems to be one of the most divergent elements of the Oxylobinae, and it is not now considered close to any part of *Ageratina*.

A GEOGRAPHICAL ANALYSIS OF THE FAMILY RANUNCULACEAE

Svetlana N. Ziman[1] *and*
Carl S. Keener[2]

ABSTRACT

The Ranunculaceae Juss. are distributed worldwide. The primary differentiation of this family apparently took place in the vast territory of Eurasia during the Paleogene at least 50 million years ago or earlier, in Cretaceous time. The western and eastern floristic centers in eastern Asia played the most significant role in the secondary differentiation (i.e., formation of most genera and some groups of species), but important additional centers of ranunculaceous differentiation were in North and South America. The distribution of many groups of this family throughout the world and their local differentiation were associated with the general fall in temperature, development of the temperate floras, and the Alpine rise of mountain ridges (Neogene and more recent epochs).

The aim of this paper is to analyze the role of the Ranunculaceae with respect to floras around the world and to define more precisely some questions concerning the origin and differentiation of this family.

To date, there is no general study of the geographical distribution of the Ranunculaceae as a whole, except those of Tamura (1966–1968), whose data on the presence of species in the various floristic regions of the earth were helpful in preparing this essay. Additionally, we took advantage of our own herbarium studies (examining specimens from KW, LW, LWS, LE, TBI, TAD, BP, and others) and the observations of the senior author during several expeditions through the U.S.S.R. (Ukraine, the Caucasus, the mountains of Middle Asia, and the Altai).

We follow the interpretation of the floristic regions and provinces (Table 1 and map) by Takhtajan (1970, 1978) and the interpretation of endemics in the sense of Tolmachev (1974). Furthermore, we have attempted to recognize local, disjunctive, and widespread endemic species within each province or region.

GEOGRAPHICAL CHARACTERISTICS OF THE RANUNCULACEAE

The Ranunculaceae comprise 55 genera and about 2,200 species (Takhtajan, 1987; Tamura, 1966–1968; Ziman, 1985). About 20 genera[3] and 1,200 species are endemics (Table 2). Some endemic genera, e.g., *Beesia*, *Souliea*, *Kingdonia*, *Asteropyrum*, and *Xanthorhiza*, are morphologically isolated within the Ranunculaceae, and thus we were able to use their areas to discuss peculiarities of the distribution and the differentiation of the family as a whole.

To date, five floristic regions, the Eastern Asiatic, Atlantic North American, Andean, Chile-Patagonian, and Irano-Turanian, contain at least one endemic genus.

Most genera of Ranunculaceae have disjunctive distributions. Some, e.g., *Calathodes*, *Dichocarpum*, *Urophysa*, *Semiaquilegia*, *Beesia*, *Souliea*, and *Kingdonia*, occur within restricted geographic ranges of two to four provinces in one region. Another group, made up of *Helleborus*, *Eranthis*, *Isopyrum*, *Leptopyrum*, *Paropyrum*, *Oxygra-*

[3] Bibliographic references are numbered. The nomenclature and circumscriptions of ranunculaceous genera follow monographs 4, 20, 74, 183, 187, 213, 264, 333, and others. Authorships for plant taxa follow *Index Kewensis*, Cherepanov (46), the monographs listed above, and regional floras (5 and others).

ANN. MISSOURI BOT. GARD. 76: 1012–1049. 1989.

phis, *Paraquilegia*, and *Callianthemum*, is characterized by more or less widely disjunctive areas, occupying two to four regions of Eurasia.

Areas of a third group, which includes *Trollius*, *Actaea*, *Cimicifuga*, *Enemion*, *Pulsatilla*, *Hepatica*, *Halerpestes*, and *Trautvetteria*, are represented in three to seven regions of Eurasia and North America. In many cases the disjunctive species of these genera are considered as relicts of the Tertiary temperate flora (Thorne, 1973).

Species of *Caltha* and *Myosurus* are widely distributed in the Northern and Southern hemispheres. It is remarkable that they are widespread in temperate areas but absent in the tropics and subtropics.

The distributional patterns of the remaining 18 genera of Ranunculaceae are unbroken or nearly unbroken. Species of the majority of them occur in two to six regions of Eurasia (*Aconitella* and *Ficaria*), Southeastern Asia (*Naravelia*), South America (*Hamadryas*), Africa (*Knowltonia* and *Clematopsis*), Eurasia, North Africa and North America (*Nigella*, *Aconitum*, *Consolida*, *Aquilegia*, *Adonis*, *Ceratocephalus*, and *Coptis*). *Delphinium* occurs in 11 regions of Eurasia, Africa, North America, and South America; *Thalictrum* occurs in 16 regions on these continents. Species of *Anemone*, *Clematis*, and *Ranunculus* are widespread in both hemispheres in the floras of about 30 regions.

Regional Distribution of the Ranunculaceae

In following Takhtajan (1978) we examined the distribution patterns of the Ranunculaceae in six floristic kingdoms, eight subkingdoms, 34 regions, and about 150 provinces.

HOLARCTIC KINGDOM

Location: territories of the Northern Hemisphere (more than half of the Earth), including Europe, extratropical Asia, North America, and North Africa.

Climate: predominately temperate, partly subtropical, and cold.

Ranunculaceae: 49 genera, 2,000 species.

Boreal Subkingdom

This subkingdom includes four regions: Eastern Asiatic, Circumboreal, Atlantic North American, and Rocky Mountain.

Location: extratropical Eurasia and North America.

Ranunculaceae: 48 genera, 1,500 species.

Eastern Asiatic Region

Location: main part of continental China, northern India, Burma, and Nepal, almost all Japan and Korea, eastern U.S.S.R.

Climate: warm temperate to mostly temperate.

Ranunculaceae: 38 genera, 900 species; 12 endemic genera, 400 endemic species.

Sikang Yunnan Province

Location: highlands; main part of the Chinese provinces Szechwan, Kweichow, and Yunnan, also northeastern Burma and northern Laos.

Characteristic vegetation: mountain coniferous, broad-leaved and rain forest, subalpine, and alpine formations.

Ranunculaceae: 28 genera, 400 species (14, 42, 48, 66, 81, 84, 109, 112, 199, 316).

Related floras: Central Chinese (21/60) and Eastern Himalayan (19/70).

Observations: 8 endemic genera, 180 endemic species. All endemic genera are isolated morphologically within the family. For example, *Asteropyrum* (*A. peltatum*) represents the monotypic tribe Asteropyreae and differs from other species by having simple peltate leaves. One other genus, *Souliea* (*S. vaginata*), belongs to the tribe Cimicifugeae and is distinguished by a unique type of pollen grain which lacks a primary germination apparatus (171). Another endemic monotypic genus, *Kingdonia* (*K. uniflora*), is exceptional by having open dichotomous foliar venation (42). This genus makes up the monogeneric tribe Kingdonieae, subfamily Kingdonioideae.[4] These species, also *Urophysa henryi*, *Beesia calthifolia*, *Calathodes palmata*, *C. polycarpa*, and *C. oxycarpa*, occur in isolated mountain forest locations at 2,000–4,000 m of the Sikang Yunnan, Central Chinese, Eastern Himalayan, and some other provinces.

Disjunct areas of species of *Semiaquilegia* (*S. adoxodoides* and *S. manschurica*) and *Dichocarpum* (*D. fargesii*, *D. dicarpon*, and others) are widely separated in provinces in the west and the east of the Eastern Asiatic Region. These species are also mountain forest plants, restricted to shade locations.

[4] Some systematists consider *Kingdonia* to belong to the Circaeasteraceae or else classified in its own monotypic family, Kingdoniaceae.

TABLE 1. Summary of numbers of genera and species, including endemics, of the Ranunculaceae for the principal floristic regions of the world (after Takhtajan, 297).

Kindgoms, subkingdoms, regions, provinces	Total numbers		Endemics	
	Genera	Species	Genera	Species
I. HOLARCTIC KINGDOM	49	2,000	16	1,000

In the flora of the Sikang Yunnan Province, *Aconitum* has about 70 species of which 40 are endemics; *Delphinium* has 70 species and 50 endemics; *Clematis* has 40 and 20; *Anemone* 20 and 15; *Trollius* 10 and 8; and *Aquilegia* 8 and 5 species.

In this province occur species that are important in considering the origin and dispersion of their genera and the family Ranunculaceae as a whole. For example, *Aconitum gymnandrum*, which represents the monotypic subg. *Gymnaconitum*, is found at about 4,000 m in Szechwan and in the Eastern Himalayan Province. Its annual habit is unique within *Aconitum*; this species is characterized by having primitive flowers and is considered a Tertiary relict (181, 241, 284). Another primitive species, *Delphinium aconitoides*, also occurs in this province. The local endemic *Clematis ranunculoides*, occurring there, represents the monotypic sect. *Ranunculoides*, and its life form (rosette-forming perennial herb with tripartite leaves) is regarded (341, 342) as the most primitive within *Clematis*.

There are three monotypic endemic sections of *Anemone*: sect. *Rivularis* (*A. rivularis*), sect. *Anemoclema* (*A. glaucifolia*), and sect. *Begoniifolia* (*A. begoniifolia*). Moreover, the most primitive and simultaneously relict species of *Trollius* (*T. yunnanensis*) (64, 270) and *Aquilegia* (*A. ecalcarata*) occur in the Sikang Yunnan Province (272).

The few species endemic to this province include *Delphinium ceratophorum*, *Ranunculus platypetalus*, and *Thalictrum delavayi*; many other species are shared with adjacent provinces.

Central Chinese Province

Location: Plateau Guichou, Ridges Zinlin-Dabashan and Nanlin, and the southern part of the Yangtze Basin (Kiangsu, Shensi, Hupeh, Anhwei, and Hunan provinces of China).

Characteristic vegetation: mountain forests, subalpine and alpine formations.

Ranunculaceae: 22 genera, 150 species (58, 81, 112, 198, 220, 330, 332).

Related floras: Sikang Yunnan (21/60, e.g., *Aconitum gymnandrum*, *Anemone rivularis*, *Aquilegia ecalcarata*), Eastern Himalayan (18/30, e.g., *Trollius pumilus*, *Aquilegia ecalcarata*, *Anemone obtusiloba*).

Observations: 7 endemic genera, 50 endemic species. (The endemic genera, *Asteropyrum*, *Urophysa*, *Kingdonia*, *Souliea*, *Beesia*, *Calathodes*, and *Dichocarpum*, are shared with the flora of Sikang Yunnan.) Most of the endemic species belong to *Aconitum*, *Delphinium*, *Clematis*, and *Thalictrum*. Endemic *Helleborus chinensis* together with *H. thibeticus* represent the endemic sect. *Dicarpon*. In contrast with the Sikang Yunnan flora, some species of *Pulsatilla*, e.g., *P. chinensis*, and *P. turczaninovii* are distributed here.

North Chinese Province

Location: southeastern part of the Loess Plateau and North Chinese Plain.

Characteristic vegetation: steppe formations and broad-leaved forests.

Ranunculaceae: 15 genera, 70 species (112, 139, 198, 199, 221, 332).

Related floras: Central Chinese (15/30, e.g., *Trollius chinensis*, *Cimicifuga dahurica*, *Delphinium grandiflorum*) and Manchurian (15/20, e.g., *Clematis brevicaudata*, *Thalictrum baicalense*).

Observations: no endemic genera, but 5 endem-

ic species (e.g., *Anemone changtungensis, Clematis nannophila*).

Eastern Himalayan Province

Location: main part of eastern and central Nepal, northern India, and southeastern Tibet.

Characteristic vegetation: mountain forests, subalpine and alpine formations.

Ranunculaceae: 23 genera, 200 species (35, 43, 113, 114, 123, 179, 205, 244, 261, 276, 283, 301).

Related flora: Sikang Yunnan (19/70, including endemic genera *Souliea, Beesia, Calathodes,* and *Dichocarpum*; endemic species, e.g., *Delphinium bonvalotii, Aconitum heterophyllum, Anemone rupicola,* and *Clematis connata*; and disjunct relict species, e.g., *Aconitum gymnandrum, Anemone rivularis,* and *Aquilegia ecalcarata*).

Observations: 6 endemic genera, 190 endemic species. Four of the endemic genera are shared with Sikang Yunnan Province, whereas *Archiclematis* and *Paroxygraphis* are local only. *Archiclematis alternata* grows in central Nepal in bushy border habitats at 2,200 m; *Paroxygraphis sikkimensis* is found in Sikkim in the alpine zone at 4,000 m. There are two endemic, monotypic sections of *Aconitum*: sect. *Fletcherum* (*A. fletcheranum*) and sect. *Alatospermum* (*A. novoluridum*), also the endemic, monotypic *Thalictrum*—sect. *Piuttia* (*T. rotundifolium*). Most endemic species belong to *Delphinium* (in all about 50 species with about 30 endemics, e.g., *D. nepalense*), *Aconitum* (30 and 20, e.g., *A. spicatum*), *Ranunculus* (30 and 10, e.g., *R. hirtellus*), and *Thalictrum* (20 and 10, e.g., *T. elegans*). In contrast with the Sikang Yunnan flora, this flora does consist of some species of *Pulsatilla, Coptis,* and *Hepatica.*

North Burmese Province

Location: between the Eastern Himalayan Province and Southwestern China.

Characteristic vegetation: warm temperate high-mountain forest and meadow formations.

Ranunculaceae: 14 genera, 60 species.

Related floras: Sikang Yunnan and Central Chinese (14/50, e.g., *Anemone vitifolia, A. rivularis, Cimicifuga foetida*).

Observations: 3 endemic genera, *Beesia, Souliea,* and *Dichocarpum,* about 10 endemic species (e.g., *Trollius yunnanensis, Clematis sikkimensis*).

Khasi-Manipur Province

Location: Northeastern India (Shillong Plateau, Khasi, Naga, Manipur, and Patkai Hills).

Characteristic vegetation: most like that of the North Burmese Province.

Ranunculaceae: 8 genera, 25 species.

Related flora: Eastern Himalayan (8/20, e.g., *Anemone rivularis, Clematis buchananiana*).

Observations: no endemic genera, 5 endemic species (e.g., *Trollius pumilus, Delphinium altissimum, Anemone elongata*).

Wolkano-Bonin Province

Location: small islands in Southeastern Asia (Wolkano, Bonin, and others).

Characteristic vegetation: tropical and subtropical formations.

Ranunculaceae: 2 genera, 5 species (215, 216, 299).

Related flora: Japanese-Korean (2/5, e.g., *Clematis pierotii, Ranunculus japonicus*).

Observation: no endemic genera or species.

Tokaro-Okinawa Province

Location: small islands in Southeastern Asia (Ryukyu, Tokara, Okinawa, Amami, and others).

Characteristic vegetation: tropical and subtropical formations.

Ranunculaceae: 2 genera, 7 species.

Related flora: Japanese-Korean (2/7, e.g., *Clematis mejeniana, Ranunculus ternatus*).

Observation: endemic species absent.

Taiwanian Province

Location: Taiwan and some adjacent islands, e.g., Sakisima.

Characteristic vegetation: tropical and subtropical formations, also warm-temperate, high-mountain forests and meadows.

Ranunculaceae: 9 genera, 40 species (216, 331, 339).

Related flora: Japanese-Korean (9/35, e.g., *Anemone stolonifera, Clematis uncinata, Ranunculus cantoniensis*).

Observations: 2 endemic genera, *Calathodes* and *Dichocarpum,* and 5 endemic species (e.g., *Aconitum formosanum, Ranunculus vernyi*).

Manchurian Province

Location: Soviet far east, Northeastern China, North Korea, and Northeastern Mongolia. The main landscape features are more or less level plains,

TABLE 2. The distribution of the genera of the Ranunculaceae in the main floristic regions of the world.

Genera	Regions

Conventional designations of the floristic regions:

1—Eastern Asiatic
2—Circumboreal
3—Atlantic North American
4—Rocky Mountain
5 Madrean
6—Mediterranean
7 Saharo-Arabian
8 Irano-Turanian
9—Guineo-Congo
10—Sudano-Zambesian
11—Malesian
12—Indo-Chinese
13 Indian
14—Cape
15—Caribbean
16—Andean
17—Chile-Patagonian
18—Neozeylandic
19—East Australian

but there are some mountainous chains (Sikhote-Alinj and Hingans).

Characteristic vegetation: broad-leaved and coniferous–broad-leaved forest, steppe, and meadow formations.

Ranunculaceae: 23 genera, 160 species (25, 108, 112, 158, 174, 326, 327, 328).

Related floras: Japanese-Korean (18/40, e.g., *Caltha membranacea, Actaea spicata, Enemion raddeanum, Thalictrum filamentosum*) and Okhotsk-Kamchatkian (18/25).

Observations: 1 endemic genus (*Semiaquilegia*) and about 50 endemic species, most of which belong to *Aconitum* (40 species, with about 20 endemics, e.g., *A. desoulavyi*), *Ranunculus* (30 and 5, e.g., *R. tachiroei*), and *Thalictrum* (15 and 5, e.g., *T. amurense*). In contrast to the Sikang Yunnan and other western floras of the Eastern Asiatic Region, this flora includes species of *Enemion, Hepatica, Coptis,* and *Trautvetteria* and few species of *Delphinium* and *Clematis.*

Japanese-Korean Province

Location: Honshu, Shikoku, Kyushu, southern Hokkaido, Iki, Cusima, Goto, additional small islands, and South Korea.

Characteristic vegetation: subtropical and temperate coniferous and broad-leaved forests in lowlands and mountains, also subalpine and alpine formations.

Ranunculaceae: 22 genera, 130 species (208, 216, 271, 299).

Related floras: Manchurian (18/40) and Sakhalin-Hokkaidian (16/25).

Observations: 3 endemic genera, disjunct *Semiaquilegia* and *Dichocarpum*, and local endemic *Anemonopsis* (*A. macrophylla*); these in many mountain forest locations in Honshu. Endemic species are about 50. There are endemic sections of *Anemone* (sect. *Keiskea*), *Coptis* (sect. *Japonocoptis*), *Cimicifuga* (sect. *Pityrosperma*), *Pulsatilla* (sect. *Preonanthopsis*), and *Clematis* (sects. *Patentes* and *Paratragene*). In contrast to the flora of the Manchurian Province, this flora consists of few species of *Aconitum* and lacks species of *Delphinium.*

Sakhalin-Hokkaido Province

Location: South Sakhalin, North Hokkaido, South Kuril Islands (Kunashir, Shikotan, and Iturup).

Characteristic vegetation: predominately coniferous forests.

Ranunculaceae: 17 genera, 80 species (209, 216, 299, 325, 326, 327, 328).

Related floras: Manchurian (16/40, e.g., *Caltha fistulosa, Trollius macropetalus, Aconitum arcuatum*), Japanese-Korean (16/25, e.g., *Aconitum volubile, Anemone raddeana, Adonis amurensis, Trautvetteria japonica*) and Okhotsk-Kamchatkian (14/20, e.g., *Caltha sibirica, Clematis ochotensis*).

Observations: 1 endemic monotypic genus *Miyakea* (*M. integrifolia*) which is related to *Pulsatilla* and 20 endemic species (e.g., *Aconitum miyabei, Anemone yesoensis, Pulsatilla sachalinensis*). In contrast to the Manchurian and Japanese-Korean floras, this flora has no temperate species of *Eranthis, Enemion,* and *Hepatica.*

Circumboreal Region

Location: main part of Europe (except extreme south), the Caucasus, Urals, Siberia, Kamchatka, North Sakhalin, North Kuril, the Aleutian Islands, Alaska, and northern Canada.

Climate: temperate to cold.

Ranunculaceae: 30 genera, 600 species. Endemic genera are absent; there are about 200 endemic species.

Okhotsk-Kamchatka Province

Location: Kamchatka Peninsula, littoral zones along the Okhotsk Sea, North Sakhalin and North Kuril, Komandor and Aleutian Islands.

Characteristic vegetation: predominately coniferous forests.

Ranunculaceae: 18 genera, 90 species (6, 18, 25, 125, 160, 322, 325, 328).

Related floras: most similar to the Manchurian (18/25, e.g., *Caltha fistulosa, Coptis trifolia, Aconitum fischeri*), Sakhalin-Hokkaidian (17/35, e.g., *Trollius macropetalus, Cimicifuga simplex, Aquilegia flabellata*), Northeastern-Siberian (13/30, e.g., *Trollius riederianus, Anemone debilis, Pulsatilla dahurica*), Arctic (10/15, e.g., *Caltha arctica, Trollius membranostylis, Anemone richardsonii*).

Observations: 15 endemic species (e.g., *Aconitum kurilense, Pulsatilla taraoi, Ranunculus recurvatus*). Numbers of species are noteworthy in *Ranunculus* (25), *Aconitum* (10), *Anemone* (10), and *Thalictrum* (10).

Northeastern Siberian Province

Location: northeastern U.S.S.R. (eastern Yakutia, Magadan district; Verkhoyansk, Chersky, and

Suntar-Hayata ridges; Jana-Indigirka, Kolyma, Anadyrj, and Korjakya uplands).

Characteristic vegetation: undersized and thinly growing mountain forests (of *Larix*), sparse groves of trees (e.g., *Pinus*), high-mountain tundras, alpine stone deserts.

Ranunculaceae: 15 genera, 70 species (25, 134, 135, 142, 151, 152, 154, 176).

Related floras: Okhotsk-Kamchatkian (13/30), Manchurian (12/20, e.g., *Actaea erythrocarpa, Aquilegia parviflora, Delphinium cheilanthum*) and Arctic (12/30, e.g., *Caltha arctica, Delphinium brachycentrum, Anemone multiceps*).

Observations: 5 endemic species (e.g., *Trollius chartosepalus, Pulsatilla magadanense, Ranunculus jacuticus*). There are some nemoral Tertiary relicts (*Anemone dichotoma, Pulsatilla dahurica, Ranunculus repens*; 135, 154, 308).

Middle Siberian Province

Location: North Siberia, between the Enisey and Lena rivers (mainly Middle Siberian and Aldan plateaus).

Characteristic vegetation: taiga, composed of coniferous forests (predominately *Larix sibirica*).

Ranunculaceae: 18 genera, 100 species (7, 25, 142, 175, 231).

Related flora: Northeastern Siberian (14/35, e.g., *Cimicifuga simplex, Delphinium crassifolium, Aconitum macrorhynchum, Anemone reflexa*).

Observations: 20 endemic species (e.g., *Aconitum contractum, Ranunculus borealis, R. smirnovii*). There are some nemoral Tertiary relicts (*Anemone altaica, A. sylvestris, Thalictrum foetidum*; 166, 195), Quaternary relicts (*Trollius asiaticus, Aquilegia sibirica, Anemone reflexa, Pulsatilla patens*; 96, 256).

Western Siberian Province

Location: North Siberia, between the Enisey and Obj rivers (Western Siberian Plain).

Characteristic vegetation: taiga (e.g., *Picea alba, Abies sibirica*).

Ranunculaceae: 15 genera, 60 species (25, 168, 169).

Related floras: Middle Siberian (14/30, e.g., *Actaea erythrocarpa, Anemone sylvestris, Ranunculus gmelinii*) and Eastern European (14/10, e.g., *Trollius europaeus, Aconitum septentrionale, Delphinium elatum*).

Observations: 5 endemic species (e.g., *Trollius kytmanovii, Anemone jenisseensis*).

Altai-Sayan Province

Location: south of Western and Middle Siberian provinces (highlands of Altai, Sayan, Kuznetskyi Alatau, Tuva, and others).

Characteristic vegetation: coniferous forests (of *Larix, Abies*, and *Pinus*); broad-leaved forests; subalpine and alpine, steppe, and tundra formations.

Ranunculaceae: 21 genera, 130 species (166, 172, 173, 195, 231, 266, 309).

Related floras: Northeastern Siberian (14/25, e.g., *Aquilegia sibirica, Anemone dichotoma, Pulsatilla flavescens, Adonis sibirica*), Transbaikalian (19/50, e.g., *Trollius lilacinus, Eranthis sibirica, Paraquilegia microphylla*), and Mongolian (18/35, e.g., *Aquilegia glandulosa, Delphinium crassifolium, Oxygraphis glacialis*).

Observations: 30 endemic species (e.g., *Aconitum sajanense, Delphinium sajanense, Pulsatilla ajanensis, Callianthemum sajanense*). Nemoral Tertiary relicts include *Actaea spicata, Cimicifuga foetida, Anemone sylvestris, Eranthis sibirica* (47, 128, 167, 182); high-mountain Quaternary relicts include *Trollius asiaticus, Anemone narcissiflora, Pulsatilla campanella* (194, 232, 256).

Transbaikalian Province

Location: Burjatia, southern parts of the Irkutsk and Chita districts (Khamar-Daban, Baikalyan and some other ridges; Vitim and Stanovoe plateaus; some depressions).

Characteristic vegetation: coniferous forest, and steppe and high-mountain formations.

Ranunculaceae: 19 genera, 100 species (142, 230, 231, 267, 319, 324).

Related floras: Altai-Sayan (19/50) and Mongolian (18/40, e.g., *Trollius ledebourii, Cimicifuga dahurica, Clematis hexapetala*).

Observations: 15 endemic species (e.g., *Aconitum montibaicalense, Aquilegia burjatica, Delphinium korschinskyanum, Ranunculus ajanensis*); large number of species of *Ranunculus* (20), *Aconitum* (15), *Thalictrum* (10), *Pulsatilla* (10), *Aquilegia* (8), and *Delphinium* (8).

Eastern European Province

Location: Southeastern Scandinavia and the European part of U.S.S.R. (mainly Russian Plain but also Crimea, Donetsk, Urals, and other highlands).

Characteristic vegetation: coniferous and broad-leaved forest, forest-steppe and meadow formations.

Ranunculaceae: 22 genera, 110 species (8, 23, 44, 96, 97, 269, 323).

Related floras: Central European (21/70, e.g., *Actaea spicata, Isopyrum thalictroides, Hepatica nobilis*), Western Siberian (14/10), and Manchurian (15/15, e.g., *Actaea erythrocarpa, Anemone reflexa, Thalictrum minus*).

Observations: 10 endemic species (e.g., *Aconitum besserianum, Delphinium sergii, Anemone biarmiensis, Ranunculus crymaeus*). There are disjunct relicts (e.g., *Anemone nemorosa, Aconitum anthora, Isopyrum thalictroides*; 156, 170). *Isopyrum thalictroides* is distributed in Central and Eastern Europe, and western Himalayas; *Pulsatilla grandis* occurs in the Alps, West Carpathians, Balkans, and Crimea, and most species of *Helleborus* (e.g., *H. purpurascens*) are distributed in Europe, but two of them (of sect. *Dicarpon*) occur in western China.

Central European Province

Location: Austria, F.R.G., G.D.R., Poland, and other countries of Central Europe, also western U.S.S.R.

Characteristic vegetation: broad-leaved forests, subalpine and alpine formations.

Ranunculaceae: 24 genera, 160 species (19, 25, 44, 49, 65, 79, 87, 119, 130, 221, 279, 291).

Related floras: Eastern European (21/70), Balkanian (23/80, e.g., *Trollius europaeus, Helleborus odorus, Aconitum paniculatum, Callianthemum coriandrifolium*), and Western Siberian (17/20, e.g., *Aconitum anthora, Anemone sylvestris*).

Observations: 20 endemic species (e.g., *Aconitum firmum, Aquilegia transsilvanica, Ranunculus carpaticus*). Most species belong to *Aconitum* (in all about 20 species, within them 10 endemics), *Aquilegia* (7 and 5), *Ranunculus* (50 and 10). Disjuncts: *Callianthemum coriandrifolium, Aconitum moldavicum*, and others.

Balkan Province

Location: main part of Yugoslavia, almost all Bulgaria, northern Greece, and the European part of Turkey.

Characteristic vegetation: high-mountain formations of forests and meadows.

Ranunculaceae: 23 genera, 140 species (44, 57, 89, 133, 317).

Related floras: Central European (23/80) and Liguro-Tyrrhenian (17/25, e.g., *Delphinium peregrinum, Anemone apennina, Pulsatilla alpina*).

Observations: 40 endemic species (e.g., *Helleborus multifidus, H. cyclophyllus*; bulb plants of the Mediterranean *Ranunculus* sect. *Ranunculastrum, Ranunculus rumelicus, R. millii*). Most species belong to *Ranunculus* (50), *Pulsatilla* (10), *Aquilegia* (8), and *Helleborus* (5 species).

Atlantic European Province

Location: Southwestern Scandinavia, Denmark, Belgium, Holland, Great Britain, Ireland, main part of France, northern F.R.G. and G.D.R., northern Spain.

Characteristic vegetation: coniferous and mostly broad-leaved forests, high-mountain formations with mixture of arctic, boreal, and nemoral elements.

Ranunculaceae: 22 genera, 110 species (44).

Related floras: Central European (22/50, e.g., *Ranunculus auricomus, R. platanifolius*) and Arctic (12/20, e.g., *Ranunculus sulphureus, R. hyperboreus*).

Observations: 20 endemic species (most of them restricted to dry rocky mountain places, e.g., *Aquilegia pyrenaica, Thalictrum tuberosum, Ranunculus pyrenaeus, R. gramineus*), including warmth-loving (e.g., *Helleborus foetidus, H. niger, Hepatica nobilis*), cold-tolerant (e.g., *Oxygraphis glacialis, Ranunculus pygmaeus*), and xerophytic (e.g., *Nigella gallica, Consolida regalis, Adonis pyrenaica*) elements.

North European Province

Location: main part of Scandinavia, northwestern U.S.S.R. (except Arctica).

Characteristic vegetation: coniferous forests (of *Picea abies* and *Pinus sylvestris*).

Ranunculaceae: 15 genera, 50 species (25, 44, 197, 207, 240).

Related floras: Atlantic and Central European.

Observations: no endemic species; most genera are represented with one or two species, except *Ranunculus* (about 25 species).

Arctic Province

Location: extreme northern Eurasia and North America.

Characteristic vegetation: tundra formations.

Ranunculaceae: 12 genera, 80 species (126, 136, 153, 164, 176, 197, 234, 313).

Related floras: Eurasiatic and Canadian taiga

(10/50, e.g., *Aquilegia sibirica, Anemone sylvestris, Ranunculus monophyllus*), also high-mountain zones (12/40, e.g., *Anemone narcissiflora, Oxygraphis glacialis, Thalictrum alpinum*).

Observations: few endemic species. About 50 species are widely distributed in Eurasia, and about 30 species occur in Eurasia and North America (e.g., *Delphinium chamissonis, Anemone richardsonii, Ranunculus affinis*). Hypoarctic elements include *Delphinium middendorffii, Ranunculus gmelinii*, and others); arctic elements include *Caltha caespitosa, Ranunculus sabinii, R. punctatus*, and others.

Caucasian Province

Location: Big and Little Caucasus mountains, Dagestan and Stavropolje hills and adjacent territories.

Characteristic vegetation: coniferous and broad-leaved (*Quercus* and *Fagus*) forests, mountain-steppe, subalpine and alpine formations.

Ranunculaceae: 19 genera, 160 species (90, 101, 102, 103, 149, 150).

Related floras: Euxinian (16/65, e.g., endemics *Trollius ranunculinus, Helleborus caucasicus, Delphinium dasycarpum, Ranunculus helenae, Ranunculus loykae, R. abchasisus*, and others), Armeno-Iranian (17/40, e.g., *Delphinium foetidum, Aconitum orientale, Pulsatilla albana, Ranunculus brutius*) and Central European (17/10, e.g., *Anemone nemorosa, Ranunculus repens*).

Observations: 45 endemic species, with most occurring in subalpine and alpine zones (e.g., *Pulsatilla aurea, Delphinium caucasicum, D. speciosum, Ranunculus baidarae, R. acutilobus*).

Euxine Province

Location: western part of the Caucasian Isthmus (Abkhasia, Adjaria, and adjacent territories).

Characteristic vegetation: like the Caucasian Province.

Ranunculaceae: 18 genera, 100 species (57, 103, 149, 157).

Related flora: Caucasian (16/65, including 25 endemic species).

Observations: 35 endemic species. In contrast to the Caucasian flora, this flora does not possess annuals of *Myosurus* and *Ceratocephalus* but does include a few perennials of *Anemone, Clematis, Delphinium* (sect. *Diedropetala*), and *Ranunculus* sect. *Ranunculastrum*).

Canadian Province

Location: Canada (Labrador, Hudson Bay, and Mackenzie districts) and Alaska.

Characteristic vegetation: coniferous forests (mainly of *Pinus, Picea*, and *Larix*).

Ranunculaceae: 13 genera, 60 species (26, 86, 99, 100, 115, 245, 315).

Related floras: Sitka-Oregonian (13/25, e.g., *Aconitum columbianum, Aquilegia formosa, Ranunculus macounii*), Appalachian (13/15, e.g., *Actaea rubra, Aquilegia canadensis, Ranunculus cymbalaria*), and Arctic (13/10, e.g., *Aconitum delphinifolium, Delphinium brachycentrum, Anemone multifida*).

Observations: few endemic species (e.g., *Ranunculus occidentalis, Thalictrum occidentalis*).

Atlantic North American Region

Location: eastern North America (from the coast of the Atlantic Ocean to the Great Basin and from southern districts of Canada to the Gulf of Mexico).

Climate: mainly temperate.

Ranunculaceae: 20 genera, 120 species (15a, 32, 33, 55, 116, 132, 144–148, 223, 290, 305, 315).

North American Prairies Province

Location: vast treeless plain in the middle of North America (Saskatchewan and Manitoba provinces of Canada, Nebraska, Iowa, Kansas, North and South Dakota, Oklahoma, and Texas states of U.S.A.).

Characteristic vegetation: grass formations (mainly of *Andropogon, Buchloë, Stipa*, and other genera).

Ranunculaceae: 12 genera, 40 species.

Related flora: Appalachian (11/18, e.g., *Aquilegia canadensis, Clematis virginiana, Thalictrum revolutum*).

Observations: 1 endemic species (*Clematis fremontii*).

Atlantic-Gulf Coastal Plain Province

Location: Coastal Plain territories in southeastern U.S.A. (parts of North Carolina, Virginia, Florida, Alabama, Mississippi, Arkansas, and Louisiana).

Characteristic vegetation: salt strands, dune, pine barrens, bog, marsh, beach and sea coast formations.

Ranunculaceae: 7 genera, 20 species.

Related flora: Appalachian (7/15, e.g., *Actaea pachypoda, Clematis virginiana*).

Observations: few endemic species (e.g., *Thalictrum cooleyi*).

Appalachian Province

Location: southeastern and south-central Canada (Ontario, Manitoba, and Quebec) and northeastern and central states of U.S.A. (Minnesota, Wisconsin, New York, Pennsylvania, Kentucky, Tennessee, and others). Mainly mountain territories (Piedmont Uplands, Alleghany, Blue Ridge, Catskill, Cumberland, Green, White mountains, Ozark Plateau, and others).

Characteristic vegetation: broad-leaved forests (*Fagus*, *Quercus*, *Acer*), with less representation of coniferous forests (*Pinus*, *Picea*, *Abies*, and other genera).

Ranunculaceae: 20 genera, 100 species.

Related floras: Canadian (13/15), Manchurian (16/5).

Observations: 3 endemic genera, 20 endemic species. All endemic genera are monotypic and are isolated morphologically within the family, e.g., *Hydrastis* (*H. canadensis*), *Xanthorhiza* (*X. simplicissima*) (stands apart from *Coptis*), and *Anemonella* (*A. thalictroides*). Endemic species belong mainly to *Clematis* (e.g., *C. addisonii*, *C. coactilis*), *Thalictrum* (*T. cooleyi*, *T. subrotundum*, and others), and *Ranunculus* (e.g., *R. harveyi*, *R. alleghaniensis*).

Rocky Mountain Region

Location: western North America (western Canada, also Washington, Oregon, Wyoming, California, and other states).

Climate: temperate to rather xerophytic.

Ranunculaceae: 17 genera, 100 species (1, 54, 55, 116, 122, 228, 259, 265, 315).

Sitka-Oregon Province

Location: western islands (e.g., Vancouver), main part of British Columbia, Washington, Oregon, and northeastern California (Selkirks, Gold Russell, and Cascade mountains).

Characteristic vegetation: predominately coniferous forests (*Picea*, *Pseudotsuga*, *Abies*, and others), subalpine and alpine formations.

Ranunculaceae: 16 genera, 80 species (mainly *Caltha*, *Coptis*, *Anemone*, *Delphinium*, and *Ranunculus*).

Related flora: Rocky Mountain (15/60, e.g., *Caltha leptosepala*, *Actaea arguta*, *Pulsatilla occidentalis*, *Trautvetteria carolinensis*).

Observations: 20 endemic species (e.g., *Caltha asarifolia*, *Coptis asplenifolia*, *Delphinium oreganum*).

Rocky Mountain Province

Location: southern Wyoming, central Colorado, and northern New Mexico (Rocky Mountains).

Characteristic vegetation: like the Sitka-Oregonian but more xerophytic.

Ranunculaceae: 16 genera, 70 species (mainly *Delphinium*, about 20 species, and *Ranunculus*, about 30 species).

Related floras: Sitka-Oregonian (15/60) and Californian (15/40, e.g., *Aquilegia chrysantha*, *Enemion stipitatum*, *Delphinium andersonii*).

Observations: 15 endemic species (e.g., *Delphinium decorum*, *Ranunculus inamoenus*, *R. oresterus*). In contrast to the Sitka-Oregonian flora, this flora includes some species of *Enemion* and few species of *Caltha* and *Coptis*. *Trollius* is absent.

Madrean Subkingdom

This subkingdom includes only the Madrean Region.

Madrean Region

Location: southwestern U.S.A. (California, Nevada, Utah, New Mexico, and other states) and almost all of Mexico.

Climate: warm and hot, dry.

Ranunculaceae: 17 genera, 130 species which are restricted to mountains and are absent in deserts and chaparral formations (1, 73, 116, 214, 273, 286, 306, 315).

Californian Province

Location: main part of California.

Characteristic vegetation: predominately coniferous (*Pinus*, *Sequoia*) and broad-leaved forest (*Quercus* and other genera), also subalpine and alpine formations and chaparral.

Ranunculaceae: 16 genera, 100 species.

Related flora: Rocky Mountain (16/40).

Observations: about 25 endemic species, mostly *Delphinium* (e.g., *D. californicum*, *D. luteum*, *D. uliginosum*). In contrast to the Rocky Mountain flora, this flora includes many species of *Delphinium* (in all about 40) and several species of *Aquilegia*, and *Myosurus*.

Great Basin Province

Location: Great Plain and Colorado Plateau (western parts of Washington, Oregon, and Cali-

fornia, almost all of Nevada, Utah, northern parts of Arizona and New Mexico).

Characteristic vegetation: predominately chaparral (of *Cercocarpus* and others), few high-mountain formations.

Ranunculaceae: 11 genera, 40 species.

Related floras: Californian (11/30, e.g., *Actaea arguta, Delphinium menziesii, Anemone globosa, A. drummondii*).

Observations: few endemic species (e.g., *Delphinium depauperatum, Anemone tuberosa*).

Sonoran Province

Location: Southeastern California, partly Arizona, New Mexico, and Texas, central Mexico.

Characteristic vegetation: desert formations.

Ranunculaceae: 5 genera, about 10 species.

Related flora: Great Basin (5/5, e.g., *Delphinium parishii, Clematis lasiantha*).

Observations: endemic species are *Delphinium parryi, Anemone sphoenophylla, Clematis pauciflora, Myosurus sessilis,* and *Ranunculus andersonii.*

Province of Mexican Highlands

Location: western and eastern Mexico (Sierra Madre Mountains, United Cordilleras).

Characteristic vegetation: predominately rather xerophytic high-mountain formations.

Ranunculaceae: 5 genera, 50 species.

Related flora: Californian (all five genera, but common species are absent).

Observations: about 40 endemic species, of which most belong to *Thalictrum* (e.g., *T. peltatum, T. lanatum, T. pubigerum*), also to *Delphinium* (e.g., *D. scopulorum*) and *Anemone* (*A. mexicana,* and others).

Ancient Mediterranean Subkingdom

This subkingdom includes four regions (Saharo-Arabian, Macaronesian, Mediterranean, and Irano-Turanian).

Location: Southern Europe, Northern Africa, and Western Asia.

Ranunculaceae: 30 genera, 500 species.

Saharo-Arabian Region

Location: extratropical Sahara, main parts of the Arabian and Sinai peninsulas and adjacent territories.

Climate: warm-temperate and hot xerophytic.

Ranunculaceae: 9 genera, 35 species (23, 29, 191, 237, 292).

Saharan Province

Location: Sahara Desert from the Atlantic coast to Egypt.

Characteristic vegetation: predominately desert formations.

Ranunculaceae: 4 genera, 10 species (e.g., *Delphinium bovei, Consolida deserti, Adonis dentata*).

Related flora: Egyptian-Arabian (4/6).

Observations: few endemic species.

Egyptian-Arabian Province

Location: eastern Egypt, Arabia, and Sinai.

Characteristic vegetation: predominately desert formations, also some mountain formations.

Ranunculaceae: 9 genera, 30 species (mainly species of *Ranunculus, Consolida,* and *Delphinium*).

Related floras: Saharan (4/6, e.g., *Adonis dentata, Nigella deserti*).

Observations: few endemic species (e.g., *Nigella assyriaca, Adonis palaestina*).

Macaronesian Region

Location: Azores, Madeira, Canary and Cape Verde islands.

Ranunculaceae: 2 genera: *Clematis* (5 species) and *Ranunculus* (30 species).

Mediterranean Region

This region includes nine provinces.

Location: southern Europe, northern Africa, and western Asia Minor.

Climate: mainly subtropical and rather arid.

Ranunculaceae: 18 genera, 130 species (23, 44, 57, 191, 200, 237, 238).

Liguro-Tyrrhenian Province

Location: southern France, southwestern Italy, islands in the Tyrrhenian and Ligurian seas (e.g., Corso, Sicily, Sardinia).

Characteristic vegetation: evergreen forest and shrub formations.

Ranunculaceae: 17 genera, 60 species.

Related floras: Iberian (16/25, e.g., *Pulsatilla rubra, Clematis cirrhosa, Hepatica nobilis*) and Balkanian (15/20, e.g., *Helleborus lividus, Aconitum anthora, Pulsatilla alpina*).

Observations: about 20 endemic species, most of which are high-mountain representatives of *Aquilegia* (e.g., *A. bernardii, A. litardieri*) and *Ranunculus* (e.g., *R. cordigerus, R. rupestris*). In contrast to the Balkanian flora, this flora has

no mesophytic species of *Caltha*, *Trollius*, *Actaea*, or *Cimicifuga*. Like other Mediterranean floras, the Liguro-Tyrrhenian flora includes a large number of annuals (about 20 species, e.g., *Delphinium halteratum*, *D. pictum*, *Nigella damascena*).

Iberian Province

Location: main parts of Pyrenees Peninsula (including Cantabrian Mountains, Sierra Nevada, Central Cordilleras).

Characteristic vegetation: like the Liguro-Tyrrhenian, but also steppe formations.

Ranunculaceae: 16 genera, 50 species.

Related flora: Liguro-Tyrrhenian (16/25).

Observations: about 10 endemic species, mostly *Aconitum* (e.g., *A. nevadense*), *Delphinium* (e.g., *D. nevadense*, *D. obcordatum*), and *Ranunculus* (e.g., *R. gramineus*, *R. abnormis*). This flora differs from the former by lacking *Eranthis*, possessing fewer species of *Helleborus* and *Aquilegia*, and having more species of *Anemone* and *Pulsatilla*.

East Mediterranean Province

Location: about all of Greece, west of Asia Minor, and adjacent parts of Syria, Lebanon, and Israel.

Characteristic vegetation: predominately shrub formations (*Arbutus*, *Spartium*, and others), partly semideserts.

Ranunculaceae: 13 genera, about 50 species.

Related flora: Mesopotamian (8/25, e.g., *Consolida regalis*, *Adonis annuus*).

Observations: about 15 endemic species (e.g., *Nigella cretica*, *N. doerfleri*, *Consolida hellespontica*, *Myosurus heldreichii*, *Ranunculus creticus*). Almost all endemics and half of the ranunculaceous species are annuals. In contrast to the previously mentioned floras, this flora has no species of *Aconitum*, *Pulsatilla*, or *Hepatica* but possesses species of *Aconitella*.

Southwest Mediterranean Province

Location: southern Pyrenees Peninsula, also northwestern Africa (mainly Morocco).

Characteristic vegetation: coniferous and broad-leaved forests (mainly cut down), shrub and grass formations.

Ranunculaceae: 9 genera, about 25 species.

Related floras: South Mediterranean (7/15, e.g., *Anemone coronaria*, *Consolida orientalis*, *Delphinium staphisagria*).

Observations: few endemic species (e.g., *Clematis campaniflora*, *Delphinium sylvaticum*). Some species (e.g., *Aconitum lamarckii*, *Helleborus foetidus*) show temperate Eurasiatic affinities.

South Mediterranean Province

Location: mainly northern Algeria and Tunis.

Characteristic vegetation: like the Southwest Mediterranean.

Ranunculaceae: 7 genera, about 20 species.

Related flora: Southwest Mediterranean (7/15).

Observations: Virtually no endemic species.

Southern Moroccan Province

Location: southern Morocco.

Characteristic vegetation: shrub and grass formations of a mixture of Mediterranean and Saharan elements.

Ranunculaceae: 5 genera, about 10 species.

Related floras: Southwest Mediterranean (5/5) and Saharan (4/4).

Observations: virtually no endemic species; species are predominately annuals (e.g., *Consolida mauritanica*, *Ranunculus muricatus*).

Balearic Province

Location: islands of Majorca, Minorca, and Pitius.

Characteristic vegetation: similar to the Iberian Province.

Ranunculaceae: 9 genera, 15 species.

Related flora: Iberian (9/10, e.g., *Helleborus lividus*, *Anemone coronaria*, *Delphinium staphisagria*, *Ranunculus bullatus*).

Observations: endemic species are only *Clematis balearica* and *Ranunculus balearicus*.

Adriatic Province

Location: coastal districts of Italy, Yugoslavia, and Albania.

Characteristic vegetation: evergreen forest and shrub formations.

Ranunculaceae: 7 genera, about 15 species.

Related floras: Balkanian (5/10, e.g., *Anemone coronaria*, *Nigella damascena*), also Liguro-Tyrrhenian (7/8).

Observations: 1 endemic species, *Ranunculus garganicus*.

Krym-Novorossiysk Province

Location: small territory of the South Crimea and the northeastern Caucasus.

Characteristic vegetation: similar to most of the Mediterranean provinces.

Ranunculaceae: 10 genera, about 30 species (25, 44, 103, 258, 269).

Related floras: Eastern European (10/25, e.g., *Aquilegia vulgaris, Adonis flammea, Ranunculus sceleratus*).

Observations: virtually no endemic species.

Irano-Turanian Region

This region includes 11 provinces.

Location: vast area of Asia Minor and Anterior, Middle, and Central Asia.

Climate: temperate, but mainly arid.

Ranunculaceae: 28 genera, 400 species. One endemic genus (*Alexeya*), 180 endemic species.

Anterior Asiatic Subregion

Location: western Irano-Turanian Region.

Ranunculaceae: 28 genera, 360 species, including about 150 endemic species.

Armeno-Iranian Province

Location: Armenia, Azerbaijan, part of Turkmenia, Southeastern Turkey, Iran, Iraq, and western Afghanistan.

Characteristic vegetation: steppe, semidesert, and desert formations, scrubs, sparse growth of trees (e.g., *Juniperus, Pistacia*), also high-mountain formations.

Ranunculaceae: 24 genera, 220 species (50, 56, 57, 91, 92, 103, 149, 225, 260, 294).

Related floras: Caucasian (19/40, e.g., *Caltha polypetala, Helleborus orientalis, Delphinium foetidum, Aquilegia olympica*), Hyrcanian (12/30, e.g., *Aconitella hohenackeri, Delphinium flexuosum*), and especially Central Anatolian (18/50, *Actaea spicata, Eranthis hyemalis, Aconitum orientale, Anemone blanda*).

Observations: about 30 endemic species, of which most belong to *Ranunculus* (in all about 80 species—10 endemic, e.g., *R. crateris, R. sintenisii*), *Delphinium* (35 and 10, e.g., *D. araraticum, D. carduchorum*), and *Consolida* (30 and 5, e.g., *C. armeniaca, C. olopetala*). All these species are restricted to open limestone high-mountain locations. There are about 60 species of annuals, mainly species of *Nigella, Consolida, Adonis*, and *Myosurus*. In contrast to the Caucasian and Hyrcanian flora, this flora consists of some species with boreal and nemoral affinities in the floras of Eastern Asia (e.g., *Paropyrum anemonoides, Isopyrum thalictroides, Actaea spicata*).

Hyrcanian Province

Location: small southeastern part of the Caucasian Isthmus (Talysh Chain).

Characteristic vegetation: relict broad-leaved forests (mainly of *Quercus castaneifolia* and *Zelkova carpinifolia*).

Ranunculaceae: 14 genera, 60 species (88, 103, 260).

Related floras: Caucasian (13/40, e.g., *Delphinium foetidum, Helleborus orientalis, Trollius ranunculinus*) and Armeno-Iranian (12/30).

Observations: 5 endemic species (among them, *Ranunculus hyrcanus, Anemone caucasica*, and *Delphinium ochroleucum*). In contrast to the previous floras, there are no species of *Actaea, Aconitum, Pulsatilla*; there are many species of *Nigella* and *Consolida*.

Central Anatolian Province

Location: northwestern Asia Minor (about half of the territory of Turkey, including the Anatolian Plateau).

Characteristic vegetation: semiarid and arid grass formations.

Ranunculaceae: 18 genera, 110 species (57).

Related floras: Armeno-Iranian (18/50) and East Mediterranean (13/20, e.g., *Thalictrum orientalis, Anemone blanda, Ranunculus asiaticus*).

Observations: about 20 endemic species, of which most belong, like the Armeno-Iranian endemics, to *Ranunculus* (in all about 50 of which 5 are endemics, e.g., *R. demissus, R. fibrillosus*), *Delphinium* (10 and 5, e.g., *D. venulosum, D. ilgarense*), and *Consolida* (10 and 5, e.g., *C. raveyi, C. thirkeana*).

Mesopotamian Province

Location: mainly Syria, Iran, Iraq, Israel.

Characteristic vegetation: semidesert and desert formations.

Ranunculaceae: 8 genera, 40 species (23, 57, 225, 237, 292).

Related floras: East Mediterranean (8/25) and Egyptian-Arabian (8/15, e.g., *Nigella deserti, Adonis palaestina*).

Observations: few endemic species (e.g., *Delphinium chodatum*). Most of species are annuals.

Turkestanian Province

Location: mountain ridges and highlands within Middle Asia (Paropamiz, Badkhyz, Karabylj, Badakhshan, Gyssar, Karatau, Nuratau, Mogoltau).

Characteristic vegetation: arid high-mountain forest, shrub and grass formations.

Ranunculaceae: 19 genera, 130 species (25, 39, 140, 141, 143, 163, 219).

Related floras: Dzungaro-Tien Shanian (19/50, e.g., endemics *Ranunculus rubrocalyx, Delphinium oreophylum, Aquilegia atrovinosa, Callianthemum alatavicum*) and Armeno-Iranian (17/20, e.g., *Eranthis longistipitata, Delphinium semibarbatum, Clematis asplenifolia*).

Observations: about 50 endemic species, including *Pulsatilla kostyczewii* of the monotypic sect. *Jostemon,* also about 10 species of *Delphinium* (e.g., *D. lipskyi, D. karategini*), 25 species of *Ranunculus* (e.g., *R. mogoltavicus, R. komarovii*), 8 species of *Aquilegia* (e.g., *A. vicaria, A. darwasi*) and *Anemone* (*A. eranthioides, A. seravshanica*—in all 10). In contrast to the Armeno-Iranian flora, this flora includes only about 10 annual species and lacks *Caltha, Actaea, Helleborus,* and *Isopyrum.* Besides that, this flora includes some alpine disjuncts (e.g., *Trollius lilacinus, Delphinium brunonianum, Paraquilegia microphylla*) that are regarded as Tertiary relicts (218).

Turanian Province

Location: eastern Transcaucasia, Caspian lowland and vast plain territories of the middle asiatic republics of U.S.S.R.

Characteristic vegetation: desert, semidesert, and dry steppe formations.

Ranunculaceae: 10 genera, 50 species (25, 39, 94, 129, 162, 163, 226).

Related floras: Turkestanian (9/25, e.g., *Anemone gortschakovii, Clematis tangutica, Thalictrum isopyroides*) and Armeno-Iranian (8/15, e.g., annuals *Consolida stocksiana, Ceratocephalus falcatus, Adonis parviflora*).

Observations: no endemic species.

Western Himalayan Province

Location: northern parts of Afghanistan, Pakistan, India, and northwestern China (Nuristan, Vasiristan, Kashmir, Simla, and other highlands).

Characteristic vegetation: subtropical formations in low zones, temperate forest, subalpine and alpine formations in high zones.

Ranunculaceae: 19 genera, 100 species (123, 179, 180, 243, 257, 283, 299).

Related floras: Eastern Himalayan (17/35, including endemics *Caltha gowaniana, Trollius acaulis, Delphinium coeruleum, Thalictrum glareosum,* and others) and Dzungaro-Tien Shanian (15/25, e.g., *Trollius dschungaricus, Hepatica falconeri, Ranunculus brotherusii, R. popovii*).

Observations: 1 local endemic genus, *Alexeya* (*A. vvedenskyi*), which is closely related to *Paraquilegia* and separated from the latter (222). Endemic species are about 35 (e.g., *Aconitum heterophyllum, Clematis barbellata, Anemone tetrasepala*). There are some disjunct relicts (e.g., *Anemone vitifolia, Actaea spicata, Isopyrum thalictroides*), which are absent in other provincial floras of the Irano-Turanian Region.

Northern Baluchistanian Province

Location: parts of Iran, Afghanistan, and Pakistan (Suleyman, Toba-Kakar, Kweta-Pishin, and other ridges).

Characteristic vegetation: high-mountain arid formations.

Ranunculaceae: 14 genera, about 50 species (91, 123, 225, 299).

Related floras: Western Himalayan (12/20, e.g., *Delphinium brunonianum, Oxygraphis involucratum, Anemone narcissiflora*) and Armeno-Iranian (14/20, e.g., *Consolida rugulosa, Clematis orientalis, Thalictrum isopyroides*).

Observations: about 5 endemic species (e.g., *Delphinium incanum, Thalictrum afghanicus*).

Central Asiatic Subregion

Location: vast territories from central Tien Shan to Big Hingan (part of territory of middle asiatic republics of U.S.S.R., Mongolia, Tibet, and North China).

Climate: temperate but rather arid.

Ranunculaceae: 23 genera, 200 species, including about 60 endemic species.

Dzungaro-Tien Shan Province

Location: a part of the territory of the Kazakh Republic (Talass, Dzungar, Tarbagatai, and other ridges, also the Kazakh small ridges).

Characteristic vegetation: high-mountain forest and grass formations, also rocky desert and dry steppe formations.

Ranunculaceae: 21 genera, 130 species (25, 39, 94, 140, 163, 226).

Related floras: Central Tien Shanian (19/60, including 25 endemic species, e.g., *Trollius dschungaricus, Aconitum karakolicum, Delphinium turkestanicum, Ranunculus gelidus*), Turkestanian (19/50), and Western Himalayan (15/25).

Observations: about 40 endemic species, of which most belong to *Aquilegia* (e.g., *A. tianschanica*), *Aconitum* (e.g., *A. nemorum*), *Delphinium* (e.g., *D. batalinii*), *Anemone* (e.g., *A. almaatensis*), and *Ranunculus* (e.g., *R. regelianus*). In contrast to the Turkestanian flora, this flora includes more species of *Aconitum*, *Callianthemum*, and *Adonis* but fewer species of *Ranunculus*, *Nigella*, and *Consolida*.

Central Tien Shan Province

Location: west of the Dzungaro-Tien Shan Terskey and Kungey Alatau, also Kirgiz and Fergana ridges.

Characteristic vegetation: like the Dzungaro-Tien Shanian, but mostly steppe formations.

Ranunculaceae: 19 genera, 70 species.

Related flora: Dzungaro-Tien Shanian (19/60).

Observations: All 25 endemic species are shared with the Dzungaro-Tien Shanian flora.

Mongolian Province

Location: Mongolia, the Kashgarian and Tsaidam hollows.

Characteristic vegetation: in the northern outlying districts (Khubsugul, Khentei, Khangai, and Mongolian Altai) predominately high-mountain forest and grass formations, in the central and southern parts predominately steppe and desert formations.

Ranunculaceae: 18 genera, about 100 species (105, 106, 108).

Related floras: Transbaikalian (18/40) and Altai-Sayan (18/35).

Observations: few endemic species (e.g., *Clematis intricata*, *Adonis mongolica*, *Ranunculus mongolicus*). Several species belong to *Aconitum*, *Clematis*, and *Ranunculus*.

Tibetan Province

Location: Pamir, Tibetan, and Tsinkhai plateaus.

Characteristic vegetation: predominately high-mountain stone tundra and desert formations.

Ranunculaceae: 20 genera, about 80 species.

Related floras: Turkestanian (16/30, e.g., *Trollius micranthus*, *Callianthemum alatavicum*, *Pulsatilla kostyczewii*) and Sikang Yunnanian (13/15, e.g., *Aconitum franchetii*, *Anemone imbricata*, *Delphinium albocoeruleum*).

Observations: 10 endemic species (e.g., *Delphinium propinquum*, *Ranunculus pamiri*, *Thalictrum ruthifolium*).

The flora of the Eastern Asiatic Region is an extraordinary mixture of tropical and temperate elements, and is considered (296, 297) as the most significant center of development of the Angiosperms, possibly the area of origin.

Within this region the flora of the Sikang Yunnan Province is extremely rich with Angiosperms; therefore, some Soviet plant geographers (159, 295, 338) regarded Southwestern China as the cradle of the modern temperate flora of Eurasia and considered the latter as derived from an ancient tropical flora. Other botanists (78, 107, 109) suggested that the primary development of the temperate mesophytic forest flora of Eurasia took place within the Eurasiatic tropical flora, possibly within Southwestern China, which has been the greatest refugium for this temperate flora.

According to the paleobotanical data (131), since Late Cretaceous time the Sikang Yunnan flora was mainly a high-mountain one, which included many temperate elements. The Yunnan Plateau is one of the most ancient mountain systems, formed in the Late Cretaceous (Yanshan movement of the earth crust—224), while the Himalayas are much more recent and belong to the alpine stage of mountain development (192). Therefore, the Eastern Himalayan flora is considered young (297).

Some plant geographers (13, 280) claim that the Manchurian flora was a significant refugium of the Tertiary warm temperate forest flora and suggest that the former coniferous–broad-leaved mesophytic forests, in which temperate elements now predominate, migrated there during the Miocene and that the flora of Manchuria has scarcely changed since.

According to Maekawa (190), a warm temperate flora developed in Japan and Korea since the Oligocene-Miocene. Tanai (304) claimed that the mesophytic coniferous–broad-leaved forests that survived there are quite similar to those in Manchuria.

Our analysis of the role of the Ranunculaceae in the provincial floras of the Eastern Asiatic Region led us to postulate that the initial differentiation of many groups of this family took place there in two diverse floristic centers, western and eastern ones. The former includes the Sikang Yunnan, Eastern Himalaya, and adjacent territories, the latter coincides with Manchuria, Japan, and Sakhalin.

The western floristic center consists of ten endemic genera and about 300 endemic species of the Ranunculaceae. Most of the endemic genera *Asteropyrum*, *Urophysa*, *Kingdonia*, *Souliea*, *Beesia*, *Calathodes*, *Semiaquilegia*, and *Dichocarpum*, are distributed disjunctively in two to four

provinces of eastern Asia and only *Archiclematis* and *Paroxygraphis* are local Eastern Himalayan endemics.

Most of the endemic ranunculaceous species within the western floristic center of eastern Asia are high mountain plants, and in this area a number of species are shared with two or three adjacent provincial floras. There are 22 genera and about 60 species (including about 20 endemics) in common with the Sikang Yunnanian, Eastern Himalayan, and Central Chinese provincial floras. These floras consist of the most primitive species of *Trollius* (*T. yunnanensis*), *Anemone* (*A. rivularis*), *Clematis* (*C. ranunculoides*), and *Aquilegia* (*A. ecalcarata*), and all of these genera include sections endemic to the western part of eastern Asia. Compared with the eastern floristic center, the western one is home to species of the disjunctive Eurasiatic genera *Helleborus*, *Paropyrum*, *Paraquilegia*, and *Oxygraphis*.

All these facts confirm our opinion concerning the close connections of the floras of the previously mentioned western provinces of eastern Asia. In the region of these western provinces during past geological periods a single high-mountain flora existed which became a center of development for several genera of the Ranunculaceae (all ten endemic genera, also *Trollius*, *Aconitum*, *Aquilegia*, *Anemone*, and *Clematis*). We do not consider the Ranunculaceae in the Eastern Himalayan Province as consisting of young species; rather, we support the opinion of van Steenis (289) about their antiquity.

The eastern floristic center in eastern Asia consists of four endemic ranunculaceous genera and about 120 endemic species. Two endemic genera, *Semiaquilegia* and *Dichocarpum*, are shared with the western center and the other two genera, *Anemonopsis* and *Miyakea*, are local endemics.

Most endemic species of Ranunculaceae in the eastern part of eastern Asia are montane forest plants. There are 17 genera and about 25 species shared by Manchuria, Japan, and Sakhalin, but there are almost no endemic species shared by two or three provinces. These floras consist of endemic sections of *Cimicifuga*, *Anemone*, *Pulsatilla*, *Clematis*, and *Coptis*. In contrast to the western floristic center, in the eastern center occur species of the disjunctive Palearctic genera *Enemion* and *Trautvetteria*, comparatively few species of *Delphinium* (absent in Japan and Sakhalin), and comparatively few *Clematis* species (especially few in Manchuria).

A comparison of the roles of the Ranunculaceae in the provincial floras of the western and eastern parts of eastern Asia indicated that only one-third of the ranunculaceous genera are common to both areas (*Caltha*, *Trollius*, *Actaea*, *Cimicifuga*, *Aconitum*, *Delphinium*, *Aquilegia*, *Anemone*, *Pulsatilla*, *Adonis*, *Thalictrum*, *Ranunculus*), and all of them are shared with the flora of the Circumboreal Region.

The facts obtained as a result of our analysis are probably best explained on the basis of the hypothesis that the Ranunculaceae probably originated in the vast land mass of Eurasia, with eastern Asia as a most significant center of secondary differentiation and conservation of many ranunculaceous genera. There were two centers of formation for genera and species of Ranunculaceae, western and eastern, which developed rather independently, though some groups migrated from one to the other. In our opinion, in the high-mountain flora of Sikang Yunnan, the Eastern Himalayas, and adjacent territories the endemic genera *Asteropyrum*, *Beesia*, *Calathodes*, *Souliea*, *Urophysa*, *Kingdonia*, *Archiclematis*, and *Paroxygraphis* evolved, as did such genera as *Trollius*, *Aquilegia*, *Anemone*, and *Clematis*. Meanwhile, in the montane forest flora of Manchuria, Japan, and adjacent territories, the endemic genera *Anemonopsis*, *Miyakea*, *Semiaquilegia*, and *Dichocarpum* evolved.

Plant geographers (77, 136, 166) regarded the Altai as the refugium of the Tertiary nemoral relicts and one of the important centers of development of the high-mountain Eurasiatic flora. They proposed that many ancient Eastern Asiatic species migrated westward through the Altai. Our data on the Ranunculaceae confirm the importance of the Altai flora in the development and distribution of many Eurasiatic groups of Angiosperms. Furthermore, endemic genera and sections of the Ranunculaceae in the Siberian provincial floras are absent, and moreover, almost no species occur in all provincial floras of Siberia. These facts can be explained if one is to suppose that contacts of Siberian floras were not close.

According to Tikhomirov (308) and Vasiljev (321), the origin of Siberian taiga floristic complexes are recent (Pleistocene), but Tolmachev (310) claimed that these complexes were more ancient (Early Pliocene). Our data support the latter opinion but show that the floristic elements of the Ranunculaceae of the northern Siberian taiga were derived from Eastern Asiatic ones. Consequently, some Siberian species of *Trollius*, *Aconitum*, *Delphinium*, *Anemone*, *Ranunculus*, and *Thalictrum* are considered today as boreal or taiga elements, but they are really related to the nemoral high-

mountain elements of the more warmth-loving floras of Manchuria and western China.

Our analysis of the Ranunculaceae of the provincial floras of Europe shows the presence of 25 genera and about 250 species. Endemic ranunculaceous genera are absent, but there are about 75 endemic species restricted mainly to the Alps, Carpathians, Pyrenees, and other highlands, and include species of *Aquilegia*, *Aconitum*, *Delphinium*, *Ranunculus*, and *Thalictrum*.

The distinctive features of the European provincial floras include not only the presence within them of many common ranunculaceous species but also historical connections with the Siberian and especially with the Eastern Asiatic floras. According to Popov (236), the Eastern Asiatic and European floras have the same age, but our data show that the latter are derivative from the former. In our opinion, therefore, the majority of the Tertiary ranunculaceous groups have migrated into Europe from the east during the Pliocene and became preserved there in the Alps, Carpathians, and other mountains. More recently, in these territories intensive radiation of new groups of *Aconitum*, *Delphinium*, and *Aquilegia* took place.

Our data from analysis of the role of the Ranunculaceae in arctic regions uphold the opinion of Tolmachev (312) and Budantsev (36) concerning the comparatively recent age of the arctic floristic complexes and their derivation from boreal and partly from nemoral complexes. Contrary to some plant geographers (95, 314, 320) who consider the territory of the Arctic Province as a floristic region or a special zone without division into regions and provinces, we follow Takhtajan's (297) interpretation of this province.

The Caucasus was a remarkable center in the formation of some high-mountain groups of Angiosperms in the Late Pliocene and Pleistocene (77, 101, 102, 193, 293). These groups originated out of subtropical-forest species (complexes of the Poltava flora—170), but some of them migrated there from the east, mainly from eastern Asia.

We note also the presence within the modern Caucasian flora of 22 genera and about 230 species of Ranunculaceae (about 60 endemic). Almost all ranunculaceous genera in the Caucasian provincial floras are shared with those in the European and Siberian floras of the Circumboreal Region. Most species of these genera (*Aquilegia*, *Aconitum*, *Delphinium*, *Anemone*, *Pulsatilla*, *Clematis*, and *Thalictrum*) occur in eastern Asia and Siberia.

Some genera (e.g., *Nigella*, *Consolida*, *Ceratocephalus*) occurring in the Caucasian floras are shared with the floras of the Mediterranean Region. In the flora of the Caucasus, there are some Eurasiatic disjuncts (e.g., *Actaea spicata*, *Anemone nemorosa*), which are generally accepted as Tertiary relicts. These data led us to hypothesize close connections among the ranunculaceous groups in Eurasia (including the Caucasus) during past periods and to hypothesize possible migrations of their ancestral groups into the Caucasus from the east.

The membership within the Ranunculaceae of large numbers of Caucasian endemics indicates local differentiation of this family in the high-mountain zones, especially within *Delphinium* and *Ranunculus*. Most of the Caucasian endemic species (e.g., *Aquilegia colchica*, *Delphinium pyramidatum*, *Anemone speciosa*, *Aconitum pubiceps*, *Ranunculus helenae*) originated in the Western Caucasus (or Colkhis), which is considered to be a significant refugium of the Late Tertiary warm-temperate forest flora. Another large Tertiary floristic refugium, which was in the Eastern Caucasus (Hyrcan or Talysh), did not play a large role in the differentiation of the Ranunculaceae and hence the Talysh endemic species of this family are not numerous. The evolution of the ranunculaceous flora of these two centers developed independently, and shared endemics as well as vicariant species of Ranunculaceae are almost absent.

Some species of Ranunculaceae in the Caucasian floras are shared with the Mediterranean Region or are closely related to species there. They are predominately annual xerophytes (e.g., *Nigella arvensis*, *Consolida ambigua*, *Ceratocephalus testiculatus*, *Adonis aestivalis*). The Caucasian ranunculaceous species with connections in Anterior Asia are xerophytic and mainly annual (e.g., *Delphinium cyphoplectrum*, *Consolida divaricata*, *Nigella orientalis*, *Aconitella hohenackeri*, *Thalictrum sultabadense*). At the same time, within the ranunculaceous species shared between the Caucasus and Asia Minor, many are high-mountain, mesophytic, mainly forest plants (e.g., *Caltha polypetala*, *Trollius ranunculinus*, *Aquilegia caucasica*, *Anemone impexa*, *Pulsatilla violacea*).

All previously mentioned data led us to suggest close connections of the ranunculaceous groups in Eurasia (including the Caucasus) in past periods; possible migration into the Caucasus of some ancestral groups of this family from the east through Asia Minor and some xerophytic groups from the Mediterranean Region; evolution of some groups within the Caucasian flora itself.

According to the literature, the flora of the Appalachian Province of the Atlantic North American Region is ancient (mainly Tertiary), whereas the

flora of the North American Prairies and the Atlantic-Gulf Coastal Plain provinces are comparatively recent and derivative. Our data support this conjecture, including close relationships of the boreal floras of Eurasia with those of North America while, on the other hand, maintaining that there were relatively prolonged disconnections of the floras in the western and eastern parts of both continents (31, 98, 184). These floristic events were promoted by means of sea barriers (ancient Siberian Sea and the Straits of Mexico) and Miocene and more recent land bridges between Eurasia and North America through the Pacific and Atlantic oceans (135, 251).

Seventeen ranunculaceous genera are shared by North American and Eurasian boreal floras. It is remarkable that more than half of them (*Caltha*, *Actaea*, *Cimicifuga*, *Aconitum*, *Delphinium*, *Clematis*, *Anemone*, *Pulsatilla*, *Ranunculus*, and *Thalictrum*) consist of sections with Eurasiatic–North American distributions. Although species in common to these floras are few (e.g., *Anemone narcissiflora*, *Thalictrum alpinum*, *Ranunculus pedatifidus*), pairs of corresponding or closely related species are numerous (e.g., *Actaea spicata–A. rubra*, *Trautvetteria japonica–T. grandis*, *Enemion raddeanum–E. biternatum*).

Our analysis showed that the territories of the Appalachian and Rocky Mountain provinces were important centers of North American differentiation of the Ranunculaceae. Within the former, the relict genera *Hydrastis*, *Xanthorhiza*, and *Anemonella* evolved, and within both of them, some sections of *Trollius*, *Aquilegia*, *Ranunculus*, *Thalictrum*, *Enemion*, and *Cimicifuga*. Possibly, the two last-mentioned genera originated within these floras. Compared with the peculiarities of distribution of species of *Hydrastis*, *Xanthorhiza*, and *Anemonella* (they occur disjunctively through about ten states in the Appalachian province, e.g., Illinois, Tennessee, Virginia, and others), we regard the age of these genera (at least that of *Enemion*) as more recent than the Eastern Asiatic endemic genera (e.g., *Beesia*, *Calathodes*).

A comparison of the distribution of the Ranunculaceae in all four regions of the Boreal Subkingdom (Eastern Asiatic, Circumboreal, Atlantic North American, and Rocky Mountain) showed the considerable floristic role of this family in each. These data form the basis of our supposition that the development of the Ranunculaceae took place over a long period of time within the Tertiary warm-temperate flora which was in common to all circumpolar territories of the Northern Hemisphere (31, 296). We regard western and eastern parts of eastern Asia and eastern North America (Appalachians) as significant refugia of this ancient flora. The Altai-Sayan Ridges, Alps, Carpathians, Pyrenees, Caucasus, and the Rocky Mountains were, in our opinion, secondary centers of the differentiation of some groups of the Ranunculaceae.

In the Madrean Region of the Madrean Subkingdom all ranunculaceous species are concentrated on mountain slopes, and they are mainly members of the Californian and Mexican Highland provinces. These species are scanty in chaparral formations and absent in deserts. All genera of the Ranunculaceae are in common to those in both Eurasiatic and North American floras of the Boreal Subkingdom, but species in common are few and most of them are relict disjuncts. The mountains of California were one of the secondary centers of differentiation of *Delphinium*, and some groups of *Thalictrum* evolved in the Mexican Highlands.

Our analysis of the Ranunculaceae within the Madrean Region upholds the suspected (251, 286) relationships of many northern Californian groups of species with those in the boreal floras in both western and eastern North America, and, moreover, with those in boreal Eurasia. Stebbins & Major (251) regarded *Trautvetteria grandis*, *Delphinium californicum*, *Clematis occidentalis*, *Anemone quinquefolia*, and some other disjuncts as relicts of Tertiary deciduous mesophytic forests, although most endemic species of *Delphinium* have a more recent age, and our data confirm that hypothesis. It is remarkable that 15 genera of the Ranunculaceae are in common to the floras in the above-mentioned regions of the Boreal and Madrean subkingdoms.

The modern flora of the regions of the Ancient Mediterranean Subkingdom is rather xerophytic, but the Ancient Mediterranean flora developed as a derivative and mainly migratory one from boreal and tropical mesophytic floras. Most of the Angiosperms in the Mediterranean flora are related to corresponding Eastern Asiatic groups (Popov—235).

Within the Mediterranean Region the floras of the Liguro–Tyrrhenian and Iberian provinces are quite rich with Ranunculaceae. They are similar to the Balkanian flora of the Circumboreal Region but much different from the rest of the Mediterranean provincial floras. At the same time, the flora of the East Mediterranean Province is related to the most xerophytic provincial floras of the Irano-Turanian Region (e.g., Mesopotamian), and within the former about half of the species of Ranunculaceae are annuals.

Our analysis of the Ranunculaceae within the Mediterranean floristic provinces showed their xerophytic features (presence of many annuals and bulb plants) and clear connections with mesophytic groups of this family in the floras of the Boreal Subkingdom, especially with those in the high-mountain floras of Southern Europe.

Within the Irano-Turanian Region, most Ranunculaceae belong to the provincial floras of the Anterior Asiatic Subregion, while in the floras of the Central Asiatic Subregion there are relatively few Ranunculaceae. Most ranunculaceous representatives are concentrated in the flora of the Armeno-Iranian Province, which is surpassed worldwide for the richness of the Ranunculaceae only by the Sikang Yunnan Province. Nevertheless, the number of endemic species is remarkably low, especially as compared with the flora of the Sikang Yunnan Province (30/220 vs. 180/400—see Table 1). Within Ranunculaceae predominate species with boreal and nemoral affinities predominate in the floras of eastern Asia and South Siberia. These phenomena confirm the close connections between the Armeno-Iranian, South Siberian, and Eastern Asiatic floras and might reflect that the ancient flora of Anterior Asia was once more mesophytic.

From an analysis of the role of the Ranunculaceae in the provincial floras of the Irano-Turanian Region, we note that the highlands of Middle Asia (Pamiro-Alai, Tien Shan, and others) were sites of secondary formation of some groups of this family (more than 100 endemic species of *Aconitum*, *Delphinium*, *Aquilegia*, *Anemone*, and *Ranunculus*). The floras of the Turkestanian, Dzungaro-Tien Shan, and Central Tien Shan provinces are very similar in terms of Ranunculaceae. This phenomenon reflects the autochthonous development of the Mountain Middle Asiatic flora on the base of the ancient boreal groups of Angiosperms (Kamelin, 140, called them the Turkmenian and the Himalayan-Mediterranean branches). According to Pavlov (227) and Vykhodtsev (329), most of the Middle Asiatic mountain endemics are recent (Quaternary) and progressive, while Ovchinnikov (218) claimed that within them are some relict elements of nemoral complexes with certain Eastern Asiatic relatives (e.g., disjuncts *Trollius lilacinus*, *Delphinium brunonianum*, *Hepatica falconeri*, *Paropyrum anemonoides*). We agree therefore with Kamelin (140) that the Mountain Middle Asiatic flora, including the floras of the Tien Shan, is a single unit.

The Armeno-Iranian and Central Anatolian provincial floras are similar to the flora of the Mediterranean Region and are much different from the floras of Mountain Middle Asia. There are many annuals (species of *Consolida*, *Nigella*, and others), but almost no endemic species of the Ranunculaceae. Species in common to the floras of Mountain Middle Asia, Armeno-Iranian, and Central Anatolian provinces are few, especially within *Aconitum*, *Delphinium*, *Aquilegia*, *Anemone*, and *Pulsatilla*. Meanwhile, the two last-mentioned floras include some genera and many species shared with those in the Caucasian floras but absent in both the Middle Asiatic and Mediterranean floras (e.g., *Caltha polypetala*, *Helleborus orientalis*, *Actaea spicata*, *Isopyrum thalictroides*). It is remarkable that *Caltha*, *Helleborus*, *Actaea*, and *Isopyrum* are boreal mesophytes with many species in both the floras of the Eastern Asiatic and Circumboreal regions.

The floristic richness of the Ranunculaceae in the floras of the Western Himalayan and North Baluchistanian provinces is intermediate between the high-mountain floras of Middle and Eastern Asia.

The Ranunculaceae in the Central Asiatic provincial floras, both Mongolian and Tibetan, consist of few endemic species. The outlying northeastern districts are related to those in the Altai-Sayanian and West Chinese floras.

We conclude that the flora of the Ancient Mediterranean Subkingdom played a noteworthy role in the differentiation of the Ranunculaceae largely because of the evolution of annual (*Nigella*, *Consolida*, and *Aconitella*) and bulb plants (species of *Anemone* and *Ranunculus*). Within the high-mountain floras, some groups of ranunculaceous endemic species recently evolved.

PALAEOTROPICAL KINGDOM

Location: territories of Southeastern Asia and Africa, also adjacent islands.

Climate: mainly tropical.

Ranunculaceae: 11 genera, 100 species.

Indo-Malesian Subkingdom

This subkingdom includes four regions: Malesian, Fijian, Indo-Chinese, and Indian.

Location: Hindustan and Indo-China, also numerous islands in the Indian and Pacific oceans.

Ranunculaceae: 6 genera, 80 species.

Malesian Region

Location: south of the Malacca Peninsula, the Malaya Archipelago, New Guinea, and adjacent little islands.

Ranunculaceae: 5 genera, 60 species (12, 51, 70, 177, 178, 202, 203, 204, 287, 288, 289).

Characteristic vegetation: tropical forests in lowlands, also insular high-mountain formations.

Malaccan Province

Location: Malacca Peninsula and some little islands.

Ranunculaceae: 3 genera, 5 species (*Anemone sumatrana, Clematis smilacifolia, C. meyeniana, Naravelia dasyneura, N. laurifolia*).

Related floras: South Malesian (3/5) and Kalimantanian (2/3).

Observations: no endemic species.

Kalimantan, Moluccan, and Bismarckian Provinces

Ranunculaceae: 3/4, 1/2, and 1/1. Endemic species are few (e.g., *Ranunculus lowii*).

Philippinean Province

Ranunculaceae: 5 genera, 15 species.

Related floras: South Malesian (5/3, e.g., *Naravelia laurifolia, Clematis lechenaultiana*).

Observations: 6 endemic species (e.g., *Naravelia pauciflora, Clematis antonii, Ranunculus philippinense, Thalictrum philippinense*).

South Malesian Province

Ranunculaceae: 5 genera, 15 species.

Related floras: Malaccan (3/5) and Philippinean (5/3).

Observations: 5 endemic species (e.g., *Clematis korthalsii, Ranunculus javanicus, Thalictrum javanicum*).

Sumatran Province

Ranunculaceae: 5 genera, 10 species.

Related flora: South Malesian (5/8, e.g., common endemics *Ranunculus javanicus, Clematis javanica*, and others).

Observations: 5 endemic species (e.g., *Anemone angustiloba, Ranunculus sundaicus*).

Sulawesian Province

Ranunculaceae: 2 genera, 15 species.

Related floras: South Malesian (2/2, e.g., *Ranunculus blumei*).

Observations: about 15 endemic species (e.g., *Clematis molissima, Ranunculus celebicus, R. frigidurbis*).

Papuan Province

Ranunculaceae: 3 genera, 30 species.

Related flora: Sulawesian (2/2, e.g., *Clematis pickeringii*).

Observations: about 30 endemic species (e.g., *Clematis papuasica, C. phanerophlebia, Ranunculus bellus, R. brassii*).

Fijian Region

Location: Fiji, New Hebrides, Samoa, Tonga, and adjacent small archipelagoes.

Ranunculaceae: 3 genera, 4 species (*Clematis pickeringii, Ranunculus perindutus, R. keysseri, Thalictrum papuanum*—274).

Related flora: Papuan (2/2, e.g., *Clematis pickeringii, Thalictrum papuanum*).

This region includes the Fijian and Hebridean provinces.

Indo-Chinese Region

Location: peninsular Indo-China, adjacent continental territories (Southeastern Bangladesh, Southeastern Burma, South China, Thailand, Laos, Kampuchia, and Vietnam), also Andaman and Hainan islands.

Ranunculaceae: 6 genera, 25 species (21, 70, 277, 299, 302).

Related floras: Eastern Asiatic (6/10, e.g., *Clematis acuminata, Ranunculus chinensis, Thalictrum punduanus*) and Malesian (5/5, e.g., *Clematis smilacifolia, Naravelia laurifolia*).

Observations: few endemic species (e.g., *Clematis thaiana, Thalictrum siamense*).

Indian Region

Location: peninsular Hindustan, Ganges Plain, South Foothills of the Himalayas, and some islands (e.g., Sri Lanka).

Ranunculaceae: 6 genera, about 10 species (123, 262); all ranunculaceous species are concentrated in the high-mountain flora of the Deccan Plateau, West and East Gaty ridges.

Related floras: Eastern Himalayan (5/5, e.g., *Anemone rivularis, Clematis nutans, C. grewiaflora*), Malesian (5/3, e.g., *Anemone vitifolia, Naravelia laurifolia*), and African (5/2, e.g., *Delphinium dasycaulon* and *Clematis grata*).

Observations: few endemic species (e.g., *Clematis triloba, Naravelia zeylanica, Thalictrum dalzellii*).

Polynesian Subkingdom

Location: many islands of Polynesia, Hawaii, and Micronesia.

This subkingdom includes two regions—Polynesian and Hawaiian—and three provinces—Micronesian, Polynesian, and Hawaiian.

Ranunculaceae: 1 genus and 2 species (*Ranunculus hawaiensis* and *R. mauensis*—45).

Neocaledonian Subkingdom

This subkingdom includes only the Neocaledonian Region and the Neocaledonian Province.

Location: New Caledonia.

Climate: tropical.

Ranunculaceae: only *Clematis pickeringii* (110).

African Subkingdom

This subkingdom includes four regions—Guineo-Congo, Sudano-Zambesian, Karroo-Namib, and St. Helena and Ascension islands.

Location: main part of the African continent to latitude 20°S, also tropical deserts in the south of the Arabian Peninsula and in Anterior Asia.

Climate: tropical, but in highlands more or less temperate.

Ranunculaceae: 8 genera, 50 species (3, 34, 69, 72, 117, 121, 127, 206, 217, 242, 252, 282, 318). The Ranunculaceae are absent in tropical deserts and semideserts; are scarce in tropical rainforests and arboreal woodlands in low places of northern, western, and central tropical Africa; and are important in tropical mountain and afroalpine floras (117, 118).

Guineo-Congo Region

Location: territories adjacent to the Guinean Bay, including North Angola and the Congo Basin, and western Kenya, Tanzania, and Uganda.

Characteristic vegetation: predominately tropical forests and savannas, also highland formations in the extreme east.

Ranunculaceae: 7 genera, 40 species concentrated in the Congo Province, but absent in the Guinea Province.

Related floras: Sudano-Zambesian (6/15, e.g., *Anemone thomsonii, Clematis simensis, Delphinium leroyi, Thalictrum rhynchocarpum*), Cape (7/10, e.g., *Knowltonia transvaalensis, Delphinium leroyi, Clematopsis hombleyi, Ranunculus multifidus*), and Western Chinese (5/2, e.g., *Clematis grata* and *Delphinium dasycaulon*).

Observations: about 20 endemic species (e.g., *Delphinium macrocentron, Clematis dolichopoda, Thalictrum zernyi, Ranunculus aberdaricus*). Most species belong to *Clematis* (about 15) and *Ranunculus* (about 20). Endemic species occur mainly in the upper belts of Elgon, Kilimanjaro, Aberdare, and other mountains at elevations of 2,500–4,500 m.

Sudano-Zambesian Region

Location: vast territories of western, central, eastern, and southern Africa, also territories in the Arabian Peninsula and southwestern Asia.

Characteristic vegetation: predominately savanna and desert formations, some high-mountain areas.

This region includes the Sahelian, Nubo-Arabian, Omano-Rajastanian, Socotran, South Arabian, Sudanian, Somalo-Aethiopian, and Zambesian provinces.

Ranunculaceae: 8 genera, about 30 species mostly in the two last-mentioned provinces.

Related floras: Guineo-Congo (6/15) and Cape (6/5, e.g., *Clematis welwitchii, Clematopsis scabiosifolia, Thalictrum rhynchocarpum*).

Observations: about 10 endemic species (e.g., *Clematis inciso-dentata, Delphinium wellbyi, Ranunculus oligocarpus*).

In the floras of the Karroo-Namib Region and the region of the St. Helena and Ascension islands, Ranunculaceae are almost absent.

Madagascan Subkingdom

This subkingdom includes only the Madagascan Region.

Location: Madagascar and adjacent islands (e.g., Komory, Seychelles, and others) to the east of the African continent.

Madagascan Region

Location: Madagascar.

Characteristic vegetation: predominately tropical forests.

Ranunculaceae: 4 genera, about 10 species (e.g., *Clematis stanleyi, Clematopsis bojeri, Ranunculus madagascarensis, Knowltonia vesicatoria*—16, 252).

Related floras: Sudano-Zambesian (4/2).

Observations: few endemic species.

The Indo-Malesian Subkingdom is regarded as the greatest refugium of the Palaeotropical Angiosperms in which were preserved many endemic and relict families and genera (10, 296, 337). There are few ranunculaceous representatives, and they occur mainly in the mountain flora of this subkingdom. Lam (177) and van Steenis (287) regarded *Anemone*, *Ranunculus*, and *Thalictrum* as examples of temperate genera that penetrated the Malesian tropical mountain flora from temperate eastern Asia through ancient mountain ridges. Our data do not challenge this idea. Possibly, the Ranunculaceae migrated through Malesia in the Southern Hemisphere by two different routes. The western route went through Sumatra, Kalimantan, and Java, and the eastern one passed through the Philippines, Molucca, Sulavesi, and New Guinea. Van Steenis (288) and Aubreville (9) supposed these groups of islands to be the distinct centers of development and dispersal of the Angiosperms: the former island group was related to the Southeastern Asiatic floristic center, while the latter group was home to part of the Australo-Papuan flora.

The formation of uplands in New Guinea in the Late Oligocene limited north-to-south penetration by high-mountain Ranunculaceae (201, 202, 248). After that time some endemic groups of *Clematis* and *Ranunculus* evolved in the highlands of Malesia. Areas of some species (e.g., *Naravelia dasyneura*, *Anemone sumatrana*, *Clematis lechenaultiana*) occur in the adjacent Indo-Chinese, Malesian, and Indian regions, while some other species (e.g., *Anemone vitifolia*, *Clematis meyeniana*) occur disjunctively also in the highlands of West China, the Himalayas, and Japan. The most interesting area has *Clematis pickeringii* because it includes Malesia, New Caledonia, and northeastern Australia.

In the flora of the African Subkingdom only two genera are restricted to Africa and Madagascar: *Clematopsis*, which is related to *Clematis*, and *Knowltonia*, which is related to *Anemone*. The rest of the ranunculaceous genera (*Anemone*, *Clematis*, *Delphinium*, *Nigella*, *Ranunculus*, and *Thalictrum*) are shared by the floras of the Boreal and Ancient Mediterranean subkingdoms, and many species of them are related to the species of the latter subkingdom. For example, *Anemone thomsonii* is distributed in the alpine and subalpine belts of Mount Kilimanjaro and a related species, *A. glaucifolia*, grows in high mountains of western China. *Clematis grata* and *Delphinium dasycaulon* are common to the floras of western China, the Himalayas, and in Hindustan.

Our analysis of the distribution of the Ranunculaceae in Africa confirms Hedberg's (117, 118) and Boughey's (27) suggested existence of the Ancient Tropical Mountain flora in Africa and the possible connections between the Afro-Alpine and Boreal floras of Africa and Eurasia in past periods. We suppose that the ranunculaceous representatives migrated into Africa from Eurasia by means of some ancient land bridges (e.g., Sunda, Arabian) that existed there until the Late Cretaceous and early Quaternary (246, 250, 335). Afterwards, formation of the mountain ridges in eastern Africa (dated as Miocene) promoted development of the high-mountain groups of Ranunculaceae and migration of some of them into South Africa, where cold and temperate conditions existed until the Cretaceous (53). Few groups (e.g., species of *Clematis*, *Clematopsis*, and *Knowltonia*) migrated southward and secondarily became adapted to the tropical conditions of Africa.

CAPE KINGDOM

Location: southern tip of Africa.

This subkingdom includes only the Cape Region.

Characteristic vegetation: predominately sclerophyllous scrub and forest formations.

Ranunculaceae: 7 genera, about 30 species.

Related floras: Guineo-Congo (7/10) and Sudano-Zambesian (6/5).

Observations: about 10 endemic species (e.g., *Clematis brachiata*, *Knowltonia hirsuta*, *Ranunculus cooperi*). Some endemics (e.g., *Anemone capensis* and *A. alchemillifolia*) are related to endemics in the floras of the Eastern Asiatic Region.

The Cape flora is extraordinarily rich and distinctive (297), but the Ranunculaceae in it are rather few and are related to those in the floras of the African and Boreal subkingdoms.

NEOTROPICAL KINGDOM

Location: southern Florida in North America, lowlands of Mexico, Central America, and South America (except the extreme south), also adjacent islands.

Climate: tropical in lowlands, temperate in highlands.

Ranunculaceae: 9 genera, 70 species.

This kingdom includes five regions: Caribbean, Amazonian, Brazilian, Andean, and the Guayana Highlands.

Caribbean Region

Location: extreme southern North America (tropical Florida), almost all Central America, and some islands mainly in the Caribbean Sea.

Ranunculaceae: 3 genera, about 20 species (2, 67, 281).

Galapageian Province

Location: Galapagos Islands.

Ranunculaceae: absent.

West Indian Province

Location: Cuba, Jamaica, and other Caribbean islands.

Ranunculaceae: 2 genera, 5 species (e.g., *Clematis dioica, C. havanensis, Ranunculus cubensis*).

Central American Province

Location: Guatemala, Honduras, Nicaragua, Costa Rica, and Panama.

Ranunculaceae: 3 genera, about 20 species.

Related floras: Mexican Highlands (3/5, e.g., *Clematis haenkeana, Ranunculus donianus, Thalictrum hintonii*) and Andean (3/10, e.g., *Ranunculus flagelliformis, R. peruvianus, Thalictrum panamense*).

Observations: 6 endemic species, all *Thalictrum* (e.g., *T. guatemalense, T. standleyi*).

Region of the Guayana Highlands

Location: Guayana Plateau (southern Venezuela, western Guyana, western Colombia, and northern Brazil).

Characteristic vegetation: as in the previous and next two regions, predominately tropical forests, savannas, hylaeas, campo limpo, and chaco formations.

Ranunculaceae: 2 genera, 4 species (e.g., *Clematis dioica, Ranunculus apiifolius*).

Amazonian Region

Location: Amazon Basin in Brazil.

Ranunculaceae: 1 genus, 2 species (e.g., *Clematis brasiliana*).

Brazilian Region

Location: main part of Brazil, eastern Paraguay, Bolivia, and northern Argentina.

Ranunculaceae: 2 genera, 5 species (e.g., *Clematis hilarii, Ranunculus platensis*—186, 187, 188).

Andean Region

Location: Andean ridges from Venezuela to northern Chile. Predominately highlands with summits (e.g., Chimboraso and Christóbal Colón) of about 5,000–6,000 m.

Characteristic vegetation: predominately high-mountain formations of temperate elements.

Ranunculaceae: 9 genera, 60 species (59, 71, 83, 186, 189).

Related floras: Mexican Highlands (5/20, e.g., *Clematis sericea, Anemone decapetala, Myosurus apetalus, Thalictrum podocarpum*) and Chile-Patagonian (5/10, e.g., *Caltha sagittata, Myosurus aristatus, Anemone helleborifolia*).

Observations: 2 endemic genera and about 30 endemic species. The endemic genera, local and monotypic, are represented by *Oreithales integrifolia* and *Laccopetalum giganteum*, which are distributed in Peru, Bolivia, and Ecuador at about 4,000 m. Endemic species belong mainly to *Ranunculus* (about 20—e.g., *R. pilosus*), but some endemics include *Clematis* (e.g., *C. albo-rosea*), *Anemone* (e.g., *A. jamesonii*), and *Thalictrum* (e.g., *T. longistylum*).

Summing the data of the analysis of the Ranunculaceae in the floras of the Neotropical Kingdom, we must keep in mind that North America was separated from South America with a relatively wide sea space during Cretaceous and Paleogene time (250). On the other hand, until the Oligocene South America was joined through the subantarctic bridge with Antarctica which at that time was covered with cool temperate forests (246, 248). The Andes were formed in the Pleistocene and after that they became an important transtropical bridge for the migration of temperate floristic elements from North America to South America and vice versa (211, 246).

Species of *Thalictrum* and *Anemone multifida* migrated through the Andes from the north. In fact, most of the species allied to the Andean species are distributed in North and Central America (e.g., species of *Thalictrum*, sects. *Camptogastrum* and *Pelteria*, species of *Anemone*, series *Multifida*). But some species of *Clematis* sect. *Clematis*, subsect. *Dioicae* and *Aristatae*, *Anemone* sect. *Rivularidium*, *Caltha* sect. *Psychrophila*, and *Ranunculus* sect. *Trollianthoidea* were found almost exclusively in South America, richly represented

in the Andes and with relatives in the extreme south of the Southern Hemisphere.

The Andean high-mountain flora was one of the important centers of ranunculaceous differentiation. There are two distinct monotypic endemic genera in this flora, *Oreithales* and *Laccopetalum*. The former is hexaploid and seems to be derived from *Anemone* (32, 68); the latter differs from other Ranunculaceae by possessing a large number of nectary glands and possessing large unbroken leaves (length over 40 cm).

HOLANTARCTIC KINGDOM

Location: territory of South America to latitude 30°S, some islands in the southern extremity and New Zealand.

Climate: temperate and mainly cold.

Ranunculaceae: 8 genera, 100 species.

This kingdom includes four regions: Chile-Patagonian, Fernandezian, Neozeylandic, and South Subantarctic islands.

Chile-Patagonian Region

Location: Chile, Uruguay, central and southern Argentina, Tierra del Fuego, Falklands and other islands.

Characteristic vegetation: coniferous (*Araucaria* and other genera), deciduous and evergreen (*Nothofagus*) forests, sclerophyll shrubs, cushion heath, dry grassy places, cold boggy sites, and alpine meadow formations.

Ranunculaceae: 7 genera, 50 species (186, 188, 210, 212).

North Chilean and Middle Chilean Provinces

Location: territory of Chile.

Ranunculaceae: 8 genera, about 30 species.

Related floras: Andean (5/10), Pampean (3/5, e.g., *Caltha sagittata*, *Ranunculus biternatus*) and Magellanian (3/5, e.g., *Caltha sagittata*, *Ranunculus biternatus*).

Observations: 10 endemic species (e.g., *Anemone rigida*, *Ranunculus chilensis*). There are some species of two endemic genera, *Barneoudia* (e.g., *B. chilensis*, *B. major*) and *Hamadryas* (e.g., *H. argentea*).

Pampean Province

Location: southern Brazil, partly Argentina and Uruguay.

Ranunculaceae: 3 genera, about 10 species.

Related floras: Chilean (3/5).

Observations: few endemic species (e.g., *Anemone decapetala*, *Clematis bonariensis*).

Patagonian Province

Location: southern Argentina.

Ranunculaceae: 3 genera, 5 species (e.g., *Ranunculus patagonicus*, *Myosurus patagonicus*).

Magellanian Province

Location: Magellanian and adjacent islands.

Ranunculaceae: 3 genera, about 15 species.

Related flora: Chilean (3/5).

Observations: 10 endemic species (e.g., *Hamadryas magellanica*, *Caltha appendiculata*, *C. dioneifolia*).

Fernandesian Region

Location: Juan-Fernández and Desventuradas islands.

Ranunculaceae: absent.

South Subantarctic Islands Region

Location: Tristan d'Acunha, Kerguelen, and adjacent islands.

Ranunculaceae: 1 genus, 5 species (e.g., endemic *Ranunculus carolii*).

Neozeylandic Region

Location: New Zealand and adjacent islands.

Ranunculaceae: 5 genera, 60 species (5, 45, 80, 111, 196, 336).

Related flora: Chile-Patagonian (5/2, e.g., *Ranunculus acaulis*, *R. biternatus*).

Observations: about 55 endemic species (e.g., *Caltha obtusa*, *Clematis australis*, *Myosurus novae-zelandiae*, *Ranunculus gracilipes*). Most species occur in the South Island only, while some (e.g., *Ranunculus insignis*, *Caltha novae-zelandiae*) are distributed in North Island and South Island. The majority of species are high-mountain plants, and a few (e.g., *Clematis afoliata*, *Ranunculus rivularis*) occur in low-mountain zones or plains.

Our analysis showed that within the Holantarctic Kingdom the Ranunculaceae are distributed mainly in the temperate highlands or in very cold plains. Two endemic oligotypic genera, *Barneoudia* and *Hamadryas*, were formed in the Chile-Patagonian Region, while in the high zones of mountains of extreme southern South America and New Zealand some groups of the Ranunculaceae (mainly *Ranunculus*) developed, evidently from common

ancestors. Fisher (80) noted the predominance of polyploids within the New Zealand species of *Ranunculus* and listed 10 pairs of alpine species with one member in New Zealand and the other member a similar South American species (e.g., *R. haastii–R. semiverticillatus* and *R. nivicolus–R. caprarum*). Consequently, Fisher supposed that high-elevation New Zealand *Ranunculus* was derived from the South American one, not from Malesian species.

Mountain ridges in New Zealand formed in the Late Pliocene (248), along with the rise of the mountains in Australia and New Guinea. According to Raven (248) and Wardle (334) the initial species of *Anemone*, *Clematis*, and *Ranunculus* arrived in New Zealand from South America in the Late Pliocene or later, while species of *Caltha* already spread there in the Paleogene.

AUSTRALIAN KINGDOM

Location: Australian continent.

Ranunculaceae: 5 genera, about 50 species.

This kingdom includes the Southwest, East, and Central Australian regions.

East Australian Region

Location: Queensland, New South Wales, Victoria, and Tasmania.

Characteristic vegetation: high-mountain forest and ericoid formations.

Ranunculaceae: 5 genera, about 45 species (24, 37, 38, 52).

Related floras: Neozeylandic (2/5, e.g., *Clematis foetida*, *Ranunculus rivularis*) and Chile-Patagonian (2/3, e.g., *Ranunculus acaulis*, *R. biternatus*).

Observations: about 30 endemic species (e.g., *Anemone crassifolia*, *Caltha introloba*, *Clematis aristata*, *C. gentianoides*, *Ranunculus gunnianus*), and most of them are endemics of Tasmania only (e.g., *Ranunculus muelleri*, *R. scapigeri*).

Southwest Australian Region

Location: southwestern Australia.

Characteristic vegetation: dry and rainy sclerophyllous forests of *Casuarina* and *Eucalyptus*, also scrub.

Ranunculaceae: 2 genera, 5 species (e.g., *Clematis microphylla*, *Ranunculus lappaceus*).

Central Australian Region

Location: North Territory, Great Sandy Desert, Victoria and Gibson deserts, and other areas.

Characteristic vegetation: tropical desert and dry savanna formations.

Ranunculaceae: absent.

The Ranunculaceae in Australia are related to those in the Holantarctic floras. Thus, *Caltha introloba*, like other species of *Caltha* in the Southern Hemisphere, belongs to sect. *Psychrophila*; *Anemone crassifolia* belongs to sect. *Rivulariadium*; and Australian species of *Ranunculus* are related to South American species. Our conclusion is similar to that of Raven (248) who supposed that most high-mountain plants, including species of *Anemone* and *Ranunculus*, migrated to Australia and New Zealand from South America in the Late Pliocene or later. Raven suggested that a northern migratory route for plants into Australia through Malesia was geologically impossible because the alpine flora of New Guinea is younger than the Australian one (334). Moreover, Melville (201) included the Ranunculaceae with a group of five families that invaded in Australia from the north.

Conclusions

The peculiarities of the role of the Ranunculaceae in the floras of regions and provinces worldwide reflect the peculiarities of origin, differentiation, and distribution of this family, including the relationships of tropical, temperate, mountain, and lowland floras, and including the relationships of the floras of the Northern and Southern hemispheres.

According to paleobotanical literature (22, 60–63, 93, 253–255), there are no fossil remnants of the Ranunculaceae in the Cretaceous. The earliest such fossils, fruits of some species of *Clematis* and *Ranunculus*, are Oligocene and come from Eurasia (e.g., England, Ukraine, the Urals). Ranunculaceae are represented in Miocene deposits by remnants of few species of *Clematis*, *Ranunculus*, and *Thalictrum*. Pliocene ranunculaceous remnants belong to *Aquilegia*, *Anemone*, *Clematis*, *Ranunculus*, and *Thalictrum*, about 40 temperate species altogether. They were found in many places within the vast territories of Eurasia, North America, and South America.

These paleobotanical phenomena reflect the considerable differentiation of the Ranunculaceae and their radiation throughout the world during the Neogene. The sharp increase of the development and dispersion of the Ranunculaceae was associated with the Upper Eocene general fall of temperature and replacement of tropical and subtropical floras with temperate ones across Eurasia and North America (78, 229, 307).

There are two different opinions about the origin of the Ranunculaceae. Scharfetter (263) placed the origin within the Early Tertiary tropical flora, while Popov (235) claimed that the Ranunculaceae originated within the Neogene warm-temperate flora of Eurasia, similar to 50 other derivative angiospermous families.

We disagree with both these propositions and claim an Early Cretaceous origin and differentiation of the Ranunculaceae. This is based partly on the peculiarities of the disjunctive areas of such genera as *Caltha*, *Anemone*, *Clematis*, *Ranunculus*, and *Thalictrum*. The origin and primary differentiation of the family must have taken place after the breakup of the supercontinent Pangaea (or one like it). Our data are consistent with the horizontal drift of the continents (138, 201, 250, and others).

Development of the distinctive Holarctic and Holantarctic groups of *Caltha* (sects. *Caltha* and *Psychrophila*) occurred in temperate parts of Gondwana and Eurasia and seems likely to reflect the Middle Cretaceous differentiation of the northern and southern temperate floras. In this point we agree with Tolmachev (310) and Moore (211) who considered *Caltha* as one of the most ancient temperate Angiosperm genera.

The above-mentioned *Anemone*, *Clematis*, *Ranunculus*, and *Thalictrum* are temperate genera that occur fairly continuously throughout the montane Palaeotropics and Neotropics and suggest the routes by which their migrations could have taken place. Notably, *Anemone rivularis* and *Clematis ranunculoides* with archaic morphological features are tropical-mountain forest elements of the flora of Southeastern Asia. Boughey (27) regarded the mountain forest flora in Africa and Asia as very old and maintained that its survival to the present as an insular flora scattered discontinuously over huge land masses implies a connection with continental drift, land-bridges, and long periods of time.

Our analysis showed that the majority of species of all genera occur in mountains and that, moreover, species of more than half of the genera, including all endemics, are restricted chiefly to mountain locations. Moreover, the most numerous groups of species of large genera such as *Aconitum*, *Delphinium*, *Anemone*, *Clematis*, *Ranunculus*, and *Thalictrum* are distributed mainly in mountains. Our data confirm Rau (243) who considered the Ranunculaceae to be an important member of the high-mountain ecosystems and is the basis for supposing its origin in mountain locations.

Within temperate montane floras of the temperate regions the Ranunculaceae take fourth to seventh place, while in tropical montane habitats, the Ranunculaceae fall to 15th–17th place (70, 140).

Comparison of the ranunculaceous representatives in the modern floras of the Northern and Southern hemispheres (the former contains 51 genera and about 2,200 species of all 14 tribes, the latter is home to 11 genera and about 250 species of 5 tribes) and comparison of their endemic genera (17 genera of 10 tribes vs. 4 genera of 2 tribes, respectively) indicates that primary differentiation of the Ranunculaceae took place in the Northern Hemisphere.

From our geographical analysis together with data on comparative morphology, we propose that the ancestors of the tribes Cimicifugeae, Anemoneae, Clematideae, Aquilegieae, Asteropyreae, and Kingdonieae initially developed within the ancient floras of eastern Asia, while the tribes Coptideae (at least *Xanthorhiza*) and Hydrastideae were formed in North America. It was impossible to pinpoint the place of the development of the ancestors of the tribes Trollieae, Helleboreae, Delphinieae, Isopyreae, Ranunculeae, and Thalictreae, because some of their genera (e.g., *Beesia*, *Calathodes*, *Trollius*, *Aconitum*, *Eranthis*, *Aquilegia*, *Semiaquilegia*, *Urophysa*, and *Dichocarpum*) originated in eastern Asia, while other genera (e.g., *Helleborus*, *Nigella*, *Consolida*, *Leptopyrum*, and *Aconitella*) differentiated in the Ancient Mediterranean Subkingdom or North America (*Enemion* and *Anemonella*). Some associated in their origin and distribution with the temperate palearctic flora (*Delphinium*, *Callianthemum*, *Adonis*, *Trautvetteria*, *Isopyrum*, *Paraquilegia*, and *Paropyrum*).

In conclusion, we regard the Ranunculaceae as an ancient temperate family that originated in Cretaceous time within montane temperate floras of the Northern Hemisphere.

A REVISION OF THE NEW WORLD SPECIES OF *EHRETIA* (BORAGINACEAE)[1]

James S. Miller[2]

Abstract

Ehretia is a pantropical genus of about 50 species with centers of diversity in eastern Africa and tropical Asia. Although as many as 12 species of *Ehretia* have been recognized in the New World, field and herbarium studies suggest that the patterns of variation in the New World are best treated as three species. Most recent authors have recognized *Ehretia anacua* and *E. tinifolia* as distinct species and have distinguished several species with serrate leaf margins. Field studies suggest that characters used to differentiate species with serrate leaf margins often vary within populations or on a single individual. Thus *Ehretia latifolia* is treated in a broad sense, including all segregate species with serrate leaves.

The largest genus of the subfamily Ehretioideae, *Ehretia*, contains about 50 species (Airy-Shaw, 1973) distributed tropically and subtropically in both hemispheres. The genus is primarily Old World in distribution with more species in Africa than in Asia; Baker & Wright (1905) recognized 23 African species, mostly in eastern Africa, Johnston (1951) recognized 12 species in eastern Asia, and perhaps several more occur in the Malay archipelago and Australia. The genus is poorly represented in the New World where it ranges from Texas to Panama and the Greater Antilles. The last complete treatment of the New World species was that of Miers (1869) who recognized eight species. An additional six species were published by various authors after his work. Standley (1924) recognized seven species in Mexico and one more in Costa Rica (Standley, 1938) based on relatively few collections of the species with serrate leaf margins. With the great increase of collections available since Standley's work, initial studies suggested that the characters he used to separate the species were of questionable validity, and delimitation of the species became problematic. The present revision combines a study of herbarium specimens with extensive field study of the variation of leaf and indument characters to resolve these problems. The work is supplemented with surveys of leaf architecture and pollen morphology throughout the Ehretioideae to be published later; only results directly relevant to the New World species of *Ehretia* are included here.

In addition to problems with delimitation of species of *Ehretia* in the New World, there have been questions regarding definition of the genus. An additional aspect of this study was an examination of generic limits in the arborescent genera of Ehretioideae. Selected species of *Bourreria*, *Carmona*, *Rochefortia*, *Rotula*, and Old World species of *Ehretia* were examined.

Taxonomic History and Generic Delimitation

Patrick Browne (1756) named *Ehretia* after Georg Dionysius Ehret, the illustrator of Browne's

[1] This work was supported in part by National Geographic grant 3449-86. Fieldwork in Mexico would have been difficult without the gracious hospitality of the staff of the Instituto de Biología and the Facultad de Ciencias at the Universidad Nacional Autónoma de México. I particularly thank A. Delgado, H. Hernández, T. P. Ramamoorthy, and M. Sousa for logistical support. G. Campos organized a trip through Guerrero that would have otherwise been impossible. A. García, A. Márquez, E. Martínez, J. Myers, O. Téllez, R. Torres, and G. Urquijo provided help and companionship in the field. J. Nowicke provided encouragement and collaboration with pollen studies, M. Merello helped wtih SEM work, C. Jarvis helped with nomenclatural questions, and J. Solomon and M. Thulin provided review comments. I also thank the curators of the following herbaria for hospitality during visits or for specimens on loan: A, B, BH, BM, CAS, CR, DS, F, G, GH, IJ, K, L, LE, LL, MA, MEXU, MICH, NY, P, S, TEX, UC, US, WIS.

Ann. Missouri Bot. Gard. 76: 1050–1076. 1989.

Civil and Natural History of Jamaica. Linnaeus (1759) later validated the genus with the binomial *Ehretia tinifolia*. De Candolle (1845) significantly enlarged the concept of the genus by treating 58 species, many of which are now referred to the segregate genera *Bourreria*, *Carmona*, *Rochefortia*, and *Rotula*. De Candolle recognized four sections within *Ehretia*. All of the species of his sect. *Ehretia* are still referred to the genus but his sect. *Bourreria* was a diverse group of species now assigned to *Bourreria* and *Ehretia*. The two species that he treated in sect. *Carmona* have been considered conspecific and treated as *Carmona retusa* (Vahl) Masamune (Thulin, 1987). His fourth section, sect. *Xeroderma*, was another diverse group containing species now distributed in *Bourreria*, *Ehretia*, *Rochefortia*, and *Rotula*. Several species of sects. *Bourreria* and *Xeroderma* have since been excluded from Boraginaceae (see excluded species).

John Miers published a series of papers on the Boraginaceae shortly after De Candolle's work and treated *Ehretia* (Miers, 1869) in a more restricted sense. Miers segregated the genus *Rotula* (as *Rhabdia*) and allied it with *Ehretia* and *Cortesia* (a small genus endemic to saline areas in northern Argentina). Miers also sorted the species that most recent authors have included in *Bourreria* into *Bourreria* and *Crematomia*. *Crematomia* was characterized by having fruits with four pyrenes, each retaining an apical attachment to the stigma at maturity. Recent authors (Schulz, 1911; Nowicke, 1969; Gibson, 1970; Miller, 1988) have not accepted this as sufficient for generic recognition and have included these "*Crematomia*" species in *Bourreria*. Miers pointed out that *Bourreria* was distinct in its fleshy calyx with five marginally tomentose, valvate lobes; fleshy, rotate corollas; and fruits that at maturity divide into four angular pyrenes, each with a ridged endocarp and spongiose mesocarp.

Bentham & Hooker (1876) recognized three sections of *Ehretia*, one of which, *Carmona*, has been treated as a segregate genus by most recent authors (Johnston, 1951; Nowicke & Miller, in press). Johnston (1951) recognized their other two sections, *Euehretia* and *Bourrerioides*, in his treatment of the eastern Asian species. Although Johnston devoted most of his research career to Boraginaceae, he published little on *Ehretia* or *Bourreria*. He did recognize *Carmona* and *Rotula* as distinct from *Ehretia* (Johnston, 1951). In his treatment of the Boraginaceae of the southern West Indies (Johnston, 1949) he also considered *Bourreria* and *Rochefortia* as distinct from *Ehretia*. Hence, although Johnston never treated *Ehretia*, it appears that his generic concept was similar to that of most recent authors.

As currently defined, the Ehretioideae consist of eleven genera that segregate into four probably monophyletic groups, but the relationships among them remain obscure. Richardson (1976, 1977) separated *Tiquilia* from *Coldenia* and these two genera of prostrate plants with dry nutlets form a distinct lineage within the Ehretioideae. *Lepidocordia*, including *Antrophora* (Miller & Nowicke, in prep.), is also quite distinct from any of the other genera of the Ehretioideae, and Johnston (1950) considered the genus intermediate between the Ehretioideae and Heliotropioideae. The Argentinian endemic *Cortesia* and the Australian endemic *Halgania* comprise a questionable third group of shrubby plants of xeric regions with often trifid or unevenly toothed sclerophyllous leaves. Whether these two genera are closely related or simply share a similar appearance because of convergence in similar habitats is unclear. *Halgania* is unique in the Ehretioideae in its stamens connate around the style.

The remaining genera of Ehretioideae, *Bourreria*, *Carmona*, *Ehretia*, *Pteleocarpa*, *Rochefortia*, and *Rotula*, seem to form a rather close group. Of these only *Pteleocarpa* seems to stand apart in its unusual winged fruits. Although recent pollen studies (Nowicke & Miller, in prep.) supported recognition of *Bourreria*, *Carmona*, *Rochefortia*, and *Rotula* as distinct from *Ehretia*, they still appear closely related and form a distinct group within the subfamily. (See Table 1 for comparison.)

Thulin (1987) transferred five African species of *Ehretia* to *Bourreria*, a genus previously considered to be restricted to the Neotropics. These species seem to form a monophyletic group distinct from *Ehretia* in their valvate calyces, campanulate to urceolate corollas, and ridged endocarps. *Ehretia* is a more natural genus without these species, but they are probably distantly related to the New World species of *Bourreria*, which are characterized by rotate corollas and pollen grains with thickened ridges on each side of the colpi (Nowicke & Miller, unpublished). The characteristics of the genera closely allied to *Ehretia* are compared in Table 1 and a key to the genera of the Ehretioideae is provided below. Although Johnston (1935) included *Saccellium* in the Ehretioideae, recent pollen studies (Nowicke & Miller, in prep.) indicate that it is more closely related to the genera of the Cordioideae where Tahktajan (1987) placed it.

KEY TO THE GENERA OF THE EHRETIOIDEAE

1a. Procumbent shrubs or annual herbs; inflorescences crowded or few-flowered; fruits dry, of 4 nutlets.
  2a. Annuals with adventitious roots; leaves asymmetrical; flowers tetramerous, Old World ..... *Coldenia*
  2b. Perennials without adventitious roots; leaves symmetrical; flowers pentamerous, New World ..... *Tiquilia*
1b. Trees or erect or arching shrubs; inflorescences cymose or paniculate; fruits fleshy at least when young, but not of 4 nutlets.
  3a. Leaves sclerophyllous; low shrubs.
    4a. Anthers connate in a cone surrounding the style; Australia ..... *Halgania*
    4b. Anthers free; Argentina ..... *Cortesia*
  3b. Leaves coriaceous to membranaceous; erect shrubs or trees.
    5a. Flowers unisexual, the plants dioecious.
      6a. Plants with spines; endocarp dividing into four parts at maturity ..... *Rochefortia*
      6b. Plants lacking spines; endocarps remaining entire at maturity ..... *Lepidocordia*
    5b. Flowers all bisexual.
      7a. Style 1, entire or divided only to the middle.
        8a. Calyx valvate; fruits with a spongiose mesocarp, the endocarps with a ridged outer surface and often retaining an apical attachment with the style ..... *Bourreria*
        8b. Calyx imbricate; fruits with a fleshy to mucilaginous mesocarp, the endocarps usually not ridged and never retaining an apical attachment with the style.
          9a. Rheophytic shrubs with flexuous branches; style simple and obscurely bilobed ..... *Rotula*
          9b. Trees or shrubs; style usually divided with 2 distinct stigmas ..... *Ehretia*
      7b. Styles 2, free to the base.
        10a. Fruits compressed, with broad, reticulately winged margins; leaves entire ..... *Pteleocarpa*
        10b. Fruits drupaceous, not compressed; leaves toothed at the apex ..... *Carmona*

The New World Species of *Ehretia*

Only three of the New World species that DeCandolle (1845) included in *Ehretia* still belong to the genus. These are *Ehretia anacua* (Teran & Berl.) I. M. Johnston (as *E. elliptica* DC.), *E. latifolia* DC., and *E. tinifolia* L. Miers (1869) adopted a very narrow species concept, recognizing seven species with entire leaf margins, where only two have been recognized by recent authors (Standley, 1924; Nash & Moreno, 1981). Various authors described six New World species of *Ehretia* with serrate leaves between 1891 and 1938. Standley (1924) recognized five species with serrate leaves in Mexico and an additional one from Costa Rica (Standley, 1938). They differed in leaf shape and indument, although field studies reveal these characters are extremely variable. The present study recognizes three species of *Ehretia* in the New World. This differs from recent treatments by grouping all populations with distinctly serrate leaf margins as a single, variable species. This variation in leaf morphology of *Ehretia latifolia* is discussed in detail under that species.

The determination of the natural ranges of the three New World species is complicated by the fact that all are cultivated. *Ehretia tinifolia* is the most widely grown, often significantly outside its natural range, and the other two species are frequently planted near houses in areas where they occur naturally. These trees seem to be valued mostly for shade because of their dense crowns, and they are attractive when in flower and fruit. *Ehretia latifolia* is apparently not used for wood by local people.

Almost everyone questioned in Mexico had a different common name for the local species of *Ehretia* and because of this no common names are reported in this study.

Morphology

Habit

All species of *Ehretia* are trees or shrubs (Fig. 1). Although New World species are trees, *E. anacua* is frequently multistemmed. Habit is much more variable among the Old World species, which range from trees, like *E. acuminata* R. Br., to desert shrubs, such as *E. rigida* (Thunb.) Druce. The genus *Rotula* differs from *Ehretia* in its arching, flexuous branches associated with its rheophytic habitat. The trunk of *E. latifolia* is usually fluted, at least on mature plants (Fig. 2).

Leaves

All species of *Ehretia* have simple, alternate, nearly lanceolate to nearly round leaves. A few Old World species are extreme, for example *Ehretia saligna* R. Br. of Australia has elongate, straplike leaves. Leaf shape is variable within species, a single individual often showing a significant diversity of leaf shapes on a single branch (see *E. latifolia*).

Ehretia tinifolia and *E. anacua* have entire-

FIGURES 1, 2. Habit of *Ehretia latifolia*. — 1. Tree 8 m tall, near Guelatao, Oaxaca, Mexico. Note the dense crown. These trees are often left as shade trees after other species have been cut. — 2. Fluted trunk of the same individual. (Both vouchered by *Miller & Myers 2802* MO.)

margined leaves. In some specimens of *Ehretia anacua*, however, a few leaves exhibit short teeth along the margin. *Ehretia latifolia* is unique among the New World species in its evenly serrate leaf margins. Only rarely are the teeth short and uneven.

Leaf architecture can be valuable in delimitation of higher taxa (Hickey & Wolfe, 1975; Lorence, 1985; Levin, 1986a, b, c) and has been used within genera (Rury & Dickison, 1977). Leaves of 36 species of 10 genera of Ehretioideae were examined for leaf architectural features. Eleven species of *Ehretia* were selected, including the three New World species. Leaves were removed from herbarium collections, cleared, stained, and mounted according to methods of Dilcher (1974), and architectural features were analyzed following the system of Hickey (1973, 1977, 1979). A complete survey of the genera of the Ehretioideae will be published separately, but results are reported here for the New World species of *Ehretia* and several other taxa for comparison. Voucher specimens for the leaves examined are cited in the figure captions.

Leaves of *Ehretia* appear to be primitively brochidodromous, this being the condition in nearly all of the species, and in the closely related genera *Bourreria*, *Rochefortia*, and *Rotula*. Craspedodromous venation is restricted to the few species with serrate leaf margins. Of the New World species, *E. tinifolia* has brochidodromous venation (Fig. 4). *Ehretia latifolia* is the only New World species consistently with craspedodromous venation (Fig. 3). Although this might appear to be a conservative character, it is variable in *E. anacua*, which generally has brochidodromous venation (Fig. 7) but occasional individuals and leaves on juvenile shoots have serrate margins and semicraspedodromous venation (Fig. 6). Even in *E. acuminata*, an Old World species with serrate leaves (Fig. 5), leaves are brochidodromous with veins that arise secondarily from outer loops beyond the secondaries and extend into the teeth.

The patterns of tertiary and higher-order venation vary only slightly among the species of *Ehretia*. Generally, five or six orders are visible in most species. *Ehretia anacua* (Fig. 8) and *E. tinifolia* have randomly reticulate tertiary veins that anastomose and form a weak, composite intersecondary vein. The higher orders of venation vary from random to orthogonal reticulate. The ultimate marginal venation is looped in both of these species.

Ehretia latifolia (Fig. 9) and *E. acuminata* (Fig. 10) have randomly reticulate to weakly percurrent tertiary veins. Intersecondary veins are weak and restricted to the apical portion of the leaf, or are completely absent. Ultimate marginal venation is incomplete in *E. latifolia* but looped in *E. acuminata*.

The New World species of *Ehretia* are essentially evergreen. *Ehretia anacua* is partly deciduous only at the northern extreme of its range in Texas. *Ehretia latifolia* appears to produce most of its leaves during the onset of spring rains and hold them for about two years. Only in the population near Monte Alban, Oaxaca, in Mexico did I observe a plant that seemed to shed all of its leaves during the dry season. New leaves were emerging even as the last few old leaves dropped.

TABLE 1. Comparison of the major morphological characters of *Bourreria* (New World), *Bourreria* (African, sensu Thulin, 1987), *Carmona*, *Ehretia*, *Rochefortia*, and *Rotula*.

Characters	*Bourreria* New World	*Bourreria* African sensu Thulin	*Carmona*	*Ehretia*	*Rochefortia*	*Rotula*
Habit	trees and shrubs	trees and shrubs	shrub	trees and shrubs	trees and shrubs	rheophytic shrubs with arching branches
Leaves	entire	entire	apically retuse or trifid	entire or serrate	entire	entire
Calyx aestivation	valvate	valvate	quincuncial	quincuncial	imbricate	quincuncial
Corolla form	rotate	urceolate to campanulate	tubular	tubular to campanulate	shortly tubular	tubular
Corolla texture	leathery	thin	thin	thin	thin	thin
Fruit, number of parts	4	4	1	1, 2, or 4	4	4
Endocarp	ridged	ridged	lightly rugulose	rugulose to smooth	striate	reticulate
Mesocarp	spongiose	spongiose	fleshy	fleshy	fleshy	fleshy

INDUMENT

Standley (1924) differentiated New World species of *Ehretia* using density and thickness of hairs and presence or absence of glandular hairs. Field observations indicate that neither of these are significant in the sense that Standley used them. The widely scattered geographic pattern of plants with glandular hairs is not indicative of a monophyletic group, but rather probably a character that is expressed only rarely.

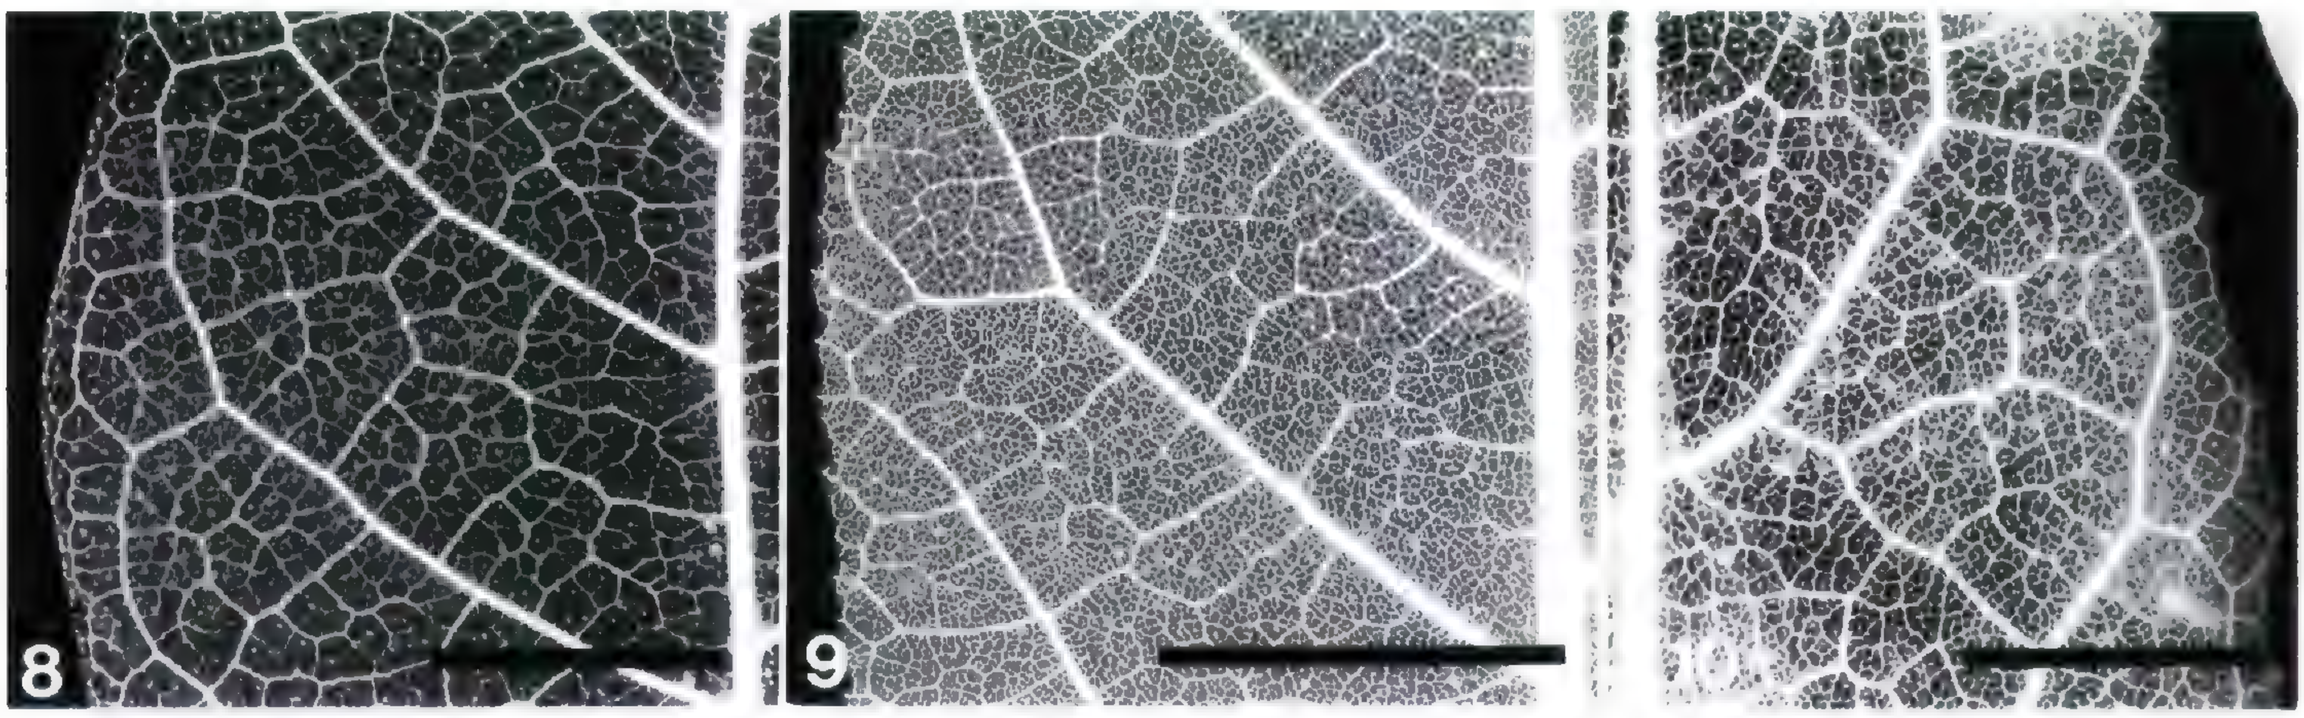
Collections of *Ehretia anacua* and *E. latifolia* show considerable variability in leaf indument, much of which can be explained as a temporal phenomenon. Young leaves of *E. latifolia* are densely and softly pubescent. Expansion of the leaf blade decreases the density of hairs, and young, fully expanded leaves are less densely pubescent with long-shafted, simple hairs from a multiple-celled, basal cystolith. During the life of an individual leaf, the majority of the brittle shafts of the hairs are often broken off and the leaf may appear nearly glabrous without magnification. As the leaf reaches senescence, the cells of the basal cystolith continue to expand and harden. The basal cystoliths with the remaining portions of the hair shafts often make up what appears to be a scabrous indument. Thus an individual leaf may pass through stages from velutinous, to sparsely pubescent, to nearly glabrous, and finally to scabrous. In the southern portion of the range of *Ehretia latifolia* the dry season is less severe. Here leaves are somewhat larger, and seldom do herbarium collections contain leaves old enough to have reached the last, seemingly scabrous, stage. These field observations suggest that indument is not a reliable character for the delimitation of segregate species from *E. latifolia*.

INFLORESCENCES

All species of *Ehretia* have many-flowered inflorescences that are cymose or are paniculate with the individual branches of the panicles cymose.

←

FIGURES 3–7. Cleared leaves of *Ehretia* species.—3. *E. latifolia* (*Miller et al. 2690* MO, Mexico). 4. *E. tinifolia* (*Miller & Téllez 3194* MO, Mexico).—5. *E. acuminata* (*Pételot 6382* MO, Vietnam). 6, 7. *E. anacua*.—6. Juvenile leaf (*E. J. Palmer 10809* MO, Texas).—7. Mature leaf (*Duke 3690* MO, Mexico). Scale bars equal 1 cm.



FIGURES 8–10. Cleared leaves of *Ehretia* species.—8. *E. anacua* (*Duke 3690* MO, Mexico).—9. *E. latifolia* (*Miller et al. 2690* MO, Mexico).—10. *E. acuminata* (*Pételot 6382* MO, Vietnam). Scale bars equal 1 cm.

The inflorescences of *Ehretia tinifolia* and *E. latifolia* have a distinct central rachis and are basically paniculate with cymose individual branches. *Ehretia anacua* has a short-pedunculate, cymose inflorescence without a central leader. This type of cymose inflorescence is widespread in the Ehretioideae and Cordioideae and is probably the primitive character state in the two subfamilies.

FLOWERS

The floral morphologies of the New World species of *Ehretia* are quite similar. *Ehretia anacua* has hairs on the corolla that are not present in *E. latifolia* or *E. tinifolia*, but other differences are small. Floral features that vary among the New World species are compared in Table 2. The Old World species are quite different and vary in numerous floral characters, including features of the calyx and size, color, and form of the corolla.

The diversity of breeding systems in the Boraginaceae is well documented (Bawa & Beach, 1981; Ganders, 1979; Vuilleumier, 1967) and second only to Rubiaceae in the number of distylous species. *Ehretia* has monomorphic, bisexual flowers with the stamens exserted and exceeding the style. This is the most common breeding system in the Ehretioideae; the only genera that differ are *Lepidocordia* (Miller & Nowicke, in prep.) and *Rochefortia* (Lefor, 1968), both dioecious. Corollas are small and white in the New World species and are visited by a wide variety of small generalistic Diptera, Hymenoptera, and Lepidoptera. The plants I observed of *Ehretia latifolia* were visited by many small insects, mostly dipterans.

POLLEN

Pollen is particularly useful in generic delimitation in the Boraginaceae (Avetissian, 1956; Nowicke & Ridgway, 1973; Nowicke & Skvarla, 1974; Nowicke & Miller, in press). Pollen of *Ehretia* is more or less prolate and three-colporate (Nowicke & Miller, in prep.). Three pseudocolpi or pseudocolpoid depressions alternate with the colpi. The apertures have elongate colpi with a bridge of ektexine over the endoaperture. The tectum is more or less complete and faintly rugulose, slightly granular, or psilate.

Ehretia is homogeneous and distinct from other genera of the Ehretioideae in its pollen morphology (Nowicke & Miller, in prep.). Evidence from pollen does not support earlier sectional divisions of the genus (see Bentham & Hooker, 1876; Johnston, 1951).

FRUITS

The fruits of *Ehretia* are drupaceous with a thin to leathery exocarp, fleshy to mucilaginous mesocarp, and bony endocarp. They vary from white, as in *E. latifolia*, through yellow and orange, as in *E. anacua*, to red, as in *E. longiflora* Champ. (Johnston, 1951). The calyx generally persists basally but is not at all accrescent. Although the stigma is usually lost, the base of the style often persists at the apex of fruits.

Fruit morphology has been important for generic delimitation in the Ehretioideae. *Bourreria*, *Carmona*, *Ehretia*, *Rochefortia*, and *Rotula* have essentially drupaceous fruits, varying in the texture of the mesocarp, number of parts into which the endocarp divides at maturity, and surface sculpturing of the endocarp. The mesocarp of these genera except for *Bourreria* is fleshy to mucilaginous. That of *Bourreria* is spongiose, being fleshy only when fruits are immature, becoming somewhat fibrous with large open air pockets.

The structure of endocarps was examined by

TABLE 2. Comparison of floral features of the New World species of *Ehretia*.

	Ehretia anacua	*E. latifolia*	*E. tinifolia*
Calyx length	2.7–3.5 mm	1.6–2.6 mm	1.5–2 mm
Calyx lobe shape	narrowly triangular	deltate to triangular	ovate
Calyx indument	pubescent to densely strigillose	glabrous to strigillose	glabrous
Corolla shape	tubular-campanulate	campanulate	campanulate
Corolla length	6–7.8 mm	3.2–6 mm	4–4.6 mm
Corolla indument	strigillose to puberulent	glabrous	glabrous
Corolla lobe shape	obovate	broadly ovate	widely oblong to oblong-ovate
Corolla lobe length	2.8–3.4 mm	1.8–2 mm	2.5–5 mm
Staminal filament length	4–6.3 mm	4–4.5 mm	3–4.5 mm
Style length	2.7–5 mm	3–4 mm	2–3.4 mm

removing mature fruits from herbarium specimens, soaking in 5% NaOH for 1–5 days to soften the exocarp and mesocarp, washing in running water until clear of all outer material, and then drying. They were then examined with an Hitachi S450 scanning electron microscope. Fruits of 54 species of ten genera of Ehretioideae were examined. *Coldenia* and *Tiquilia* stand apart in having fruits of four dry nutlets. The fruits of *Halgania*, *Lepidocordia*, and *Rotula* all differ in having a thin-walled endocarp. *Bourreria*, *Carmona*, *Ehretia*, and *Rochefortia*, however, all have somewhat similar fruits.

Fruits of *Ehretia* vary in the number of parts into which the endocarp divides. Of the species examined, *Ehretia latifolia* is the only species whose endocarp remains entire at maturity. *Ehretia acuminata*, *E. anacua*, *E. dicksonii*, and *E. tinifolia* have fruits with two separate two-seeded pyrenes at maturity. *Ehretia amoena*, *E. coerula*, *E. cymosa*, *E. laevis*, *E. obtusifolia*, and *E. rigida* have fruits with four separate single-seeded pyrenes. Of related genera, *Carmona* has an endocarp that remains entire. *Rotula* has a two-parted endocarp and *Bourreria* and *Rochefortia* have four-parted endocarps.

The surfaces of the endocarps of *Ehretia* species have distinct sculptural patterns. Two major types occur in *Ehretia*, and several others turn up in related genera. Verrucose endocarps are found in *Ehretia acuminata* (Fig. 15), *E. dicksonii*, *E. latifolia* (Fig. 13), and *E. tinifolia* (Fig. 12). *Ehretia dicksonii* is unusual among these species in having an evenly puberulent endocarp with numerous short hairs on the outer surface. Areolate endocarps, with angular depressed areas, characterize most of the Old World species with four-parted endocarps, including *E. rigida* (Fig. 14). *Ehretia anacua*, of the New World (Fig. 11), also has an areolate endocarp but differs in being less regularly areolate and in only dividing into two parts at maturity.

The endocarps of the most closely related genera are quite different in sculpturing pattern. *Carmona retusa* has an entire endocarp with few, low, broad ridges but is otherwise nearly smooth (Fig. 16). *Rochefortia* has endocarps with broad, thick, rounded ridges as exemplified by *R. spinosa* (Jacq.) Urb. (Fig. 19). *Bourreria* has ridged endocarps varying from erect, as in *B. rubra* Lott & Miller (Fig. 18), to overlapping, as in *B. nemoralis* (Gurke) Thulin (Fig. 17).

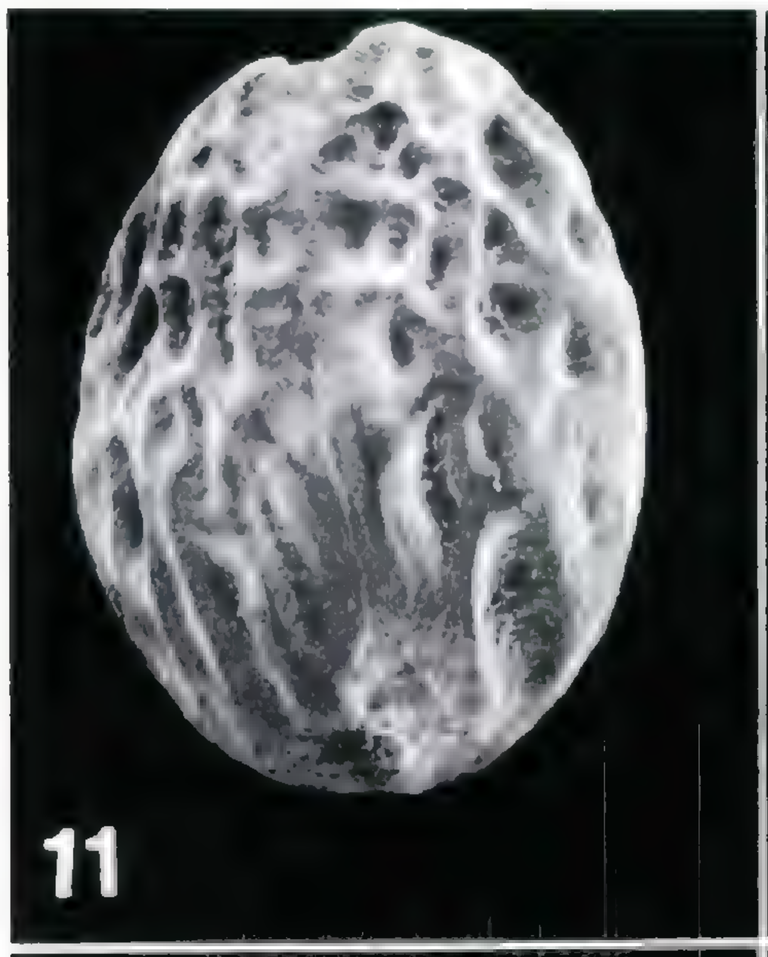
Fruit structure suggests that *Ehretia* consists of two groups. One has one- or two-parted endocarps with a verrucose surface and is found in the New World and Asia. The second has four-parted endocarps with an areolate surface and is widespread in the Old World. *Ehretia anacua* is the only New World species in the latter group but differs in having a two-parted endocarp.

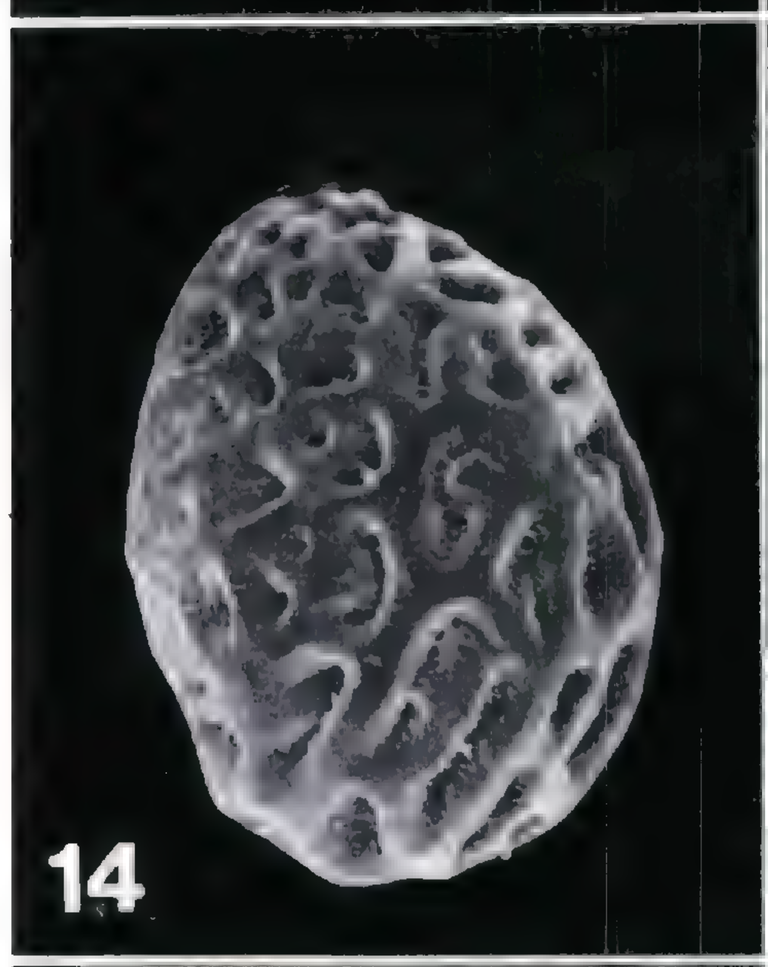
SYSTEMATIC TREATMENT

Ehretia P. Browne, Civ. Nat. Hist., Jamaica 168. 1756. TYPE: *Ehretia tinifolia* L., Syst. Nat. ed. 10. 936. 1759.

Gaza Terán & Berlandier, Mem. Comis. Limites 5. 1832. TYPE: *Gaza anacua* Terán & Berlandier, Mem. Comis. Limites 5. 1832.

Pubescent or glabrous, trees or shrubs. Leaves alternate, petiolate, the margin entire or serrate, the venation pinnate, brochidodromous or less commonly semicraspedodromous or craspedodromous. Inflorescences terminal, cymose to paniculate. Flowers bisexual; sepals 5, imbricate or open in bud; corolla white in the New World species (blue in *E. coerula* and *E. rigida*, Africa), tubular with 5 spreading to reflexed lobes or urceolate; stamens





FIGURES 11–19. Endocarps of species of Ehretioideae. 11–15. *Ehretia*.—11. *E. anacua* (*Hansen & Nee 7489* MO, Mexico). 12. *E. tinifolia* (*Miller & Myers 2824* MO, Mexico).—13. *E. latifolia* (*Purpus 5820* MO, Mexico).—14. *E. rigida* (*Armitage 305/59* MO, S Rhodesia).—15. *E. acuminata* (*Wilson 74* MO, China).—16. *Carmona retusa* (*Merrill: Species Blancoanae 3* MO, Philippines). 17, 18. *Bourreria*.—17. *B. nemoralis* (Gurke) Thulin (*Frazier 2267* MO, Kenya).—18. *B. rubra* Lott & Miller (*Lott 683* MO, Mexico).—19. *Rochefortia spinosa* Jacq. (*Liesner & Gonzalez 12160* MO, Venezuela). Scale bar equals 5 mm.

5, usually exserted, the anthers oblong to ellipsoid; ovary ovoid, 2- or 4-locular, the style 1, terminal, bifid, the stigmas 2, clavate to capitate. Fruits drupaceous, ovoid to nearly spherical, the endocarp separating into 2, 2-seeded pyrenes or into 4, 1-seeded pyrenes, or rarely remaining entire.

KEY TO THE SPECIES OF *EHRETIA* IN THE NEW WORLD

1a. Leaf margin distinctly serrate; endocarp remaining entire ..... *E. latifolia*
1b. Leaf margin entire or nearly so; endocarp dividing into 2 parts at maturity.
  2a. Upper leaf surface glabrous; inflorescence paniculate; corolla glabrous ..... *E. tinifolia*
  2b. Upper leaf surface scabrous; inflorescence cymose; corolla strigillose to puberulent ..... *E. anacua*

Ehretia anacua (Terán & Berlandier) I. M. Johnston, Contr. Gray Herb. 70: 89. 1924. *Gaza anacua* Terán & Berlandier, Mem. Comis. Limites 5. 1832. TYPE: Mexico. Tamaulipas: prope Matamoros ubi vulgo adpellatur Anacua, *Berlandier 2369* (lectotype, G, here designated; isolectotypes, BM, G, K, P).

Ehretia elliptica DC., Prodr. 9: 503. 1845. TYPE: Mexico: *Berlandier 2330* (holotype, G-DC, not seen; microfiche, MO; isotypes, BM, G, GH, K, LE, MO, NY—2 sheets, P).

Ehretia scabra Kunth & Bouché, Sp. Nov. Hort. Berol. 12. 1847. "Crescit in Mexico," no type seen.

Ehretia ciliata Miers, Ann. & Mag. Nat. Hist. Ser. IV. 3: 111. 1869. TYPE: U.S.A. Texas: *Lindheimer 665* (holotype, K; isotypes, BM, F, GH—2 sheets, K, MO—2 sheets, NY, P, US).

Ehretia exasperata Miers, Ann. & Mag. Nat. Hist. Ser. IV. 3: 112. 1869. TYPE: U.S.A. Texas: *M. Drummond 296* (holotype, K; isotypes, BM—2 sheets, GH, K, NY—2 sheets).

Ehretia lancifolia Sessé & Mociño, Fl. Mex. 51. 1894; ed. 2. 47. 1894; I. M. Johnston, J. Arnold Arbor. 30: 106. 1949. TYPE: Mexico. *Sessé et al. 5250* (lectotype, MA, here designated, photo, MO, fragment, F).

Tree 3–10(–15) m tall, often with multiple trunks, the twigs puberulent, the older wood with thick furrowed bark separating into thin gray or reddish scales. Leaves persistent or partially deciduous at northern edge of range; petioles 2–6(–11) mm long, puberulent, canaliculate adaxially; leaf blade elliptic to less commonly ovate, (1.9–) 2.3–5(–9.2) cm long, (1.2–)1.6–3.8(–5) cm wide, the apex obtuse or rarely acute to slightly acuminate, the base obtuse to rounded, rarely slightly cordate, the margin entire or sometimes unevenly serrate on some of the leaves, often somewhat revolute, the upper surface scabrous, the lower surface scabrous to puberulent, the lateral veins 4–7. Inflorescence terminal, cymose, 2.5–6 cm long, the peduncle puberulent. Flowers bisexual, fragrant; sepals 5, narrowly triangular, sometimes slightly connate basally, 2.7–3.5 mm long, 0.8–1.1 mm wide basally, pubescent to strigillose, the hairs 0.3–0.4 mm long; corolla white, 6–7.8 mm long, strigillose to puberulent on the exterior surface, 5-merous, the lobes obovate, 2.8–3.4 mm long, 1.8–2.6 mm wide, the tube 2.8–4.2 mm long; stamens 5, the filaments 4–6.3 mm long, the upper 1.8–3 mm of these free, glabrous, the anthers ellipsoid, 1.2–1.4 mm long; ovary ovoid-conical, 1.3–1.8 mm long, 0.9–1.2 mm broad, glabrous; disc not evident; style 2.7–5 mm long, the stylar branches 0.7–1.7 mm long, the stigma lobes capitate to terete. Fruits drupaceous, yellow to orange when mature, glabrous, globose, 5–8 mm diam., the endocarp dividing into 2, 2-locular pyrenes, these randomly reticulate-rugulose on the outer surface.

Distribution. *Ehretia anacua* occurs in southern Texas and northeastern Mexico from sea level to 1,300(–2,200) m in dry forests (Fig. 20). Collections from Guanajuato, Oaxaca, and Queretaro are outside the natural range of the species and are not included in the distribution map.

This common species was known as *Ehretia elliptica* DC. until Johnston (1924) discovered the older epithet published in *Gaza* Terán & Berlandier. The description of *E. scabra* indicates that it is synonymous although the brief citation of "crescit in Mexico" does not indicate a type collection. The names *E. ciliata* and *E. exasperata* are clearly synonymous; *E. ciliata* differs from *E. anacua* in no discernible characters, and the type of *E. exasperata* is merely a juvenile shoot with serrate-margined leaves. Likewise, the type of *E. lancifolia* does not differ significantly in any character from *E. anacua*. Although most type material for the names lacks adequate locality information, it seems likely that all were collected in northeastern Mexico or Texas, a region in which no other species of *Ehretia* occur.

In addition to its distinct geographic range, *E. anacua* is easily distinguished from the other New World species of *Ehretia* by its scabrous upper leaf surface, cymose inflorescence, strigillose corolla tube, and usually entire leaf margins. It is quite distinct in the genus with no apparent close relatives.

Ehretia anacua is valued for its showy flowering display and its shade. The specific epithet is derived from the common name "anacua" (Nuevo León,

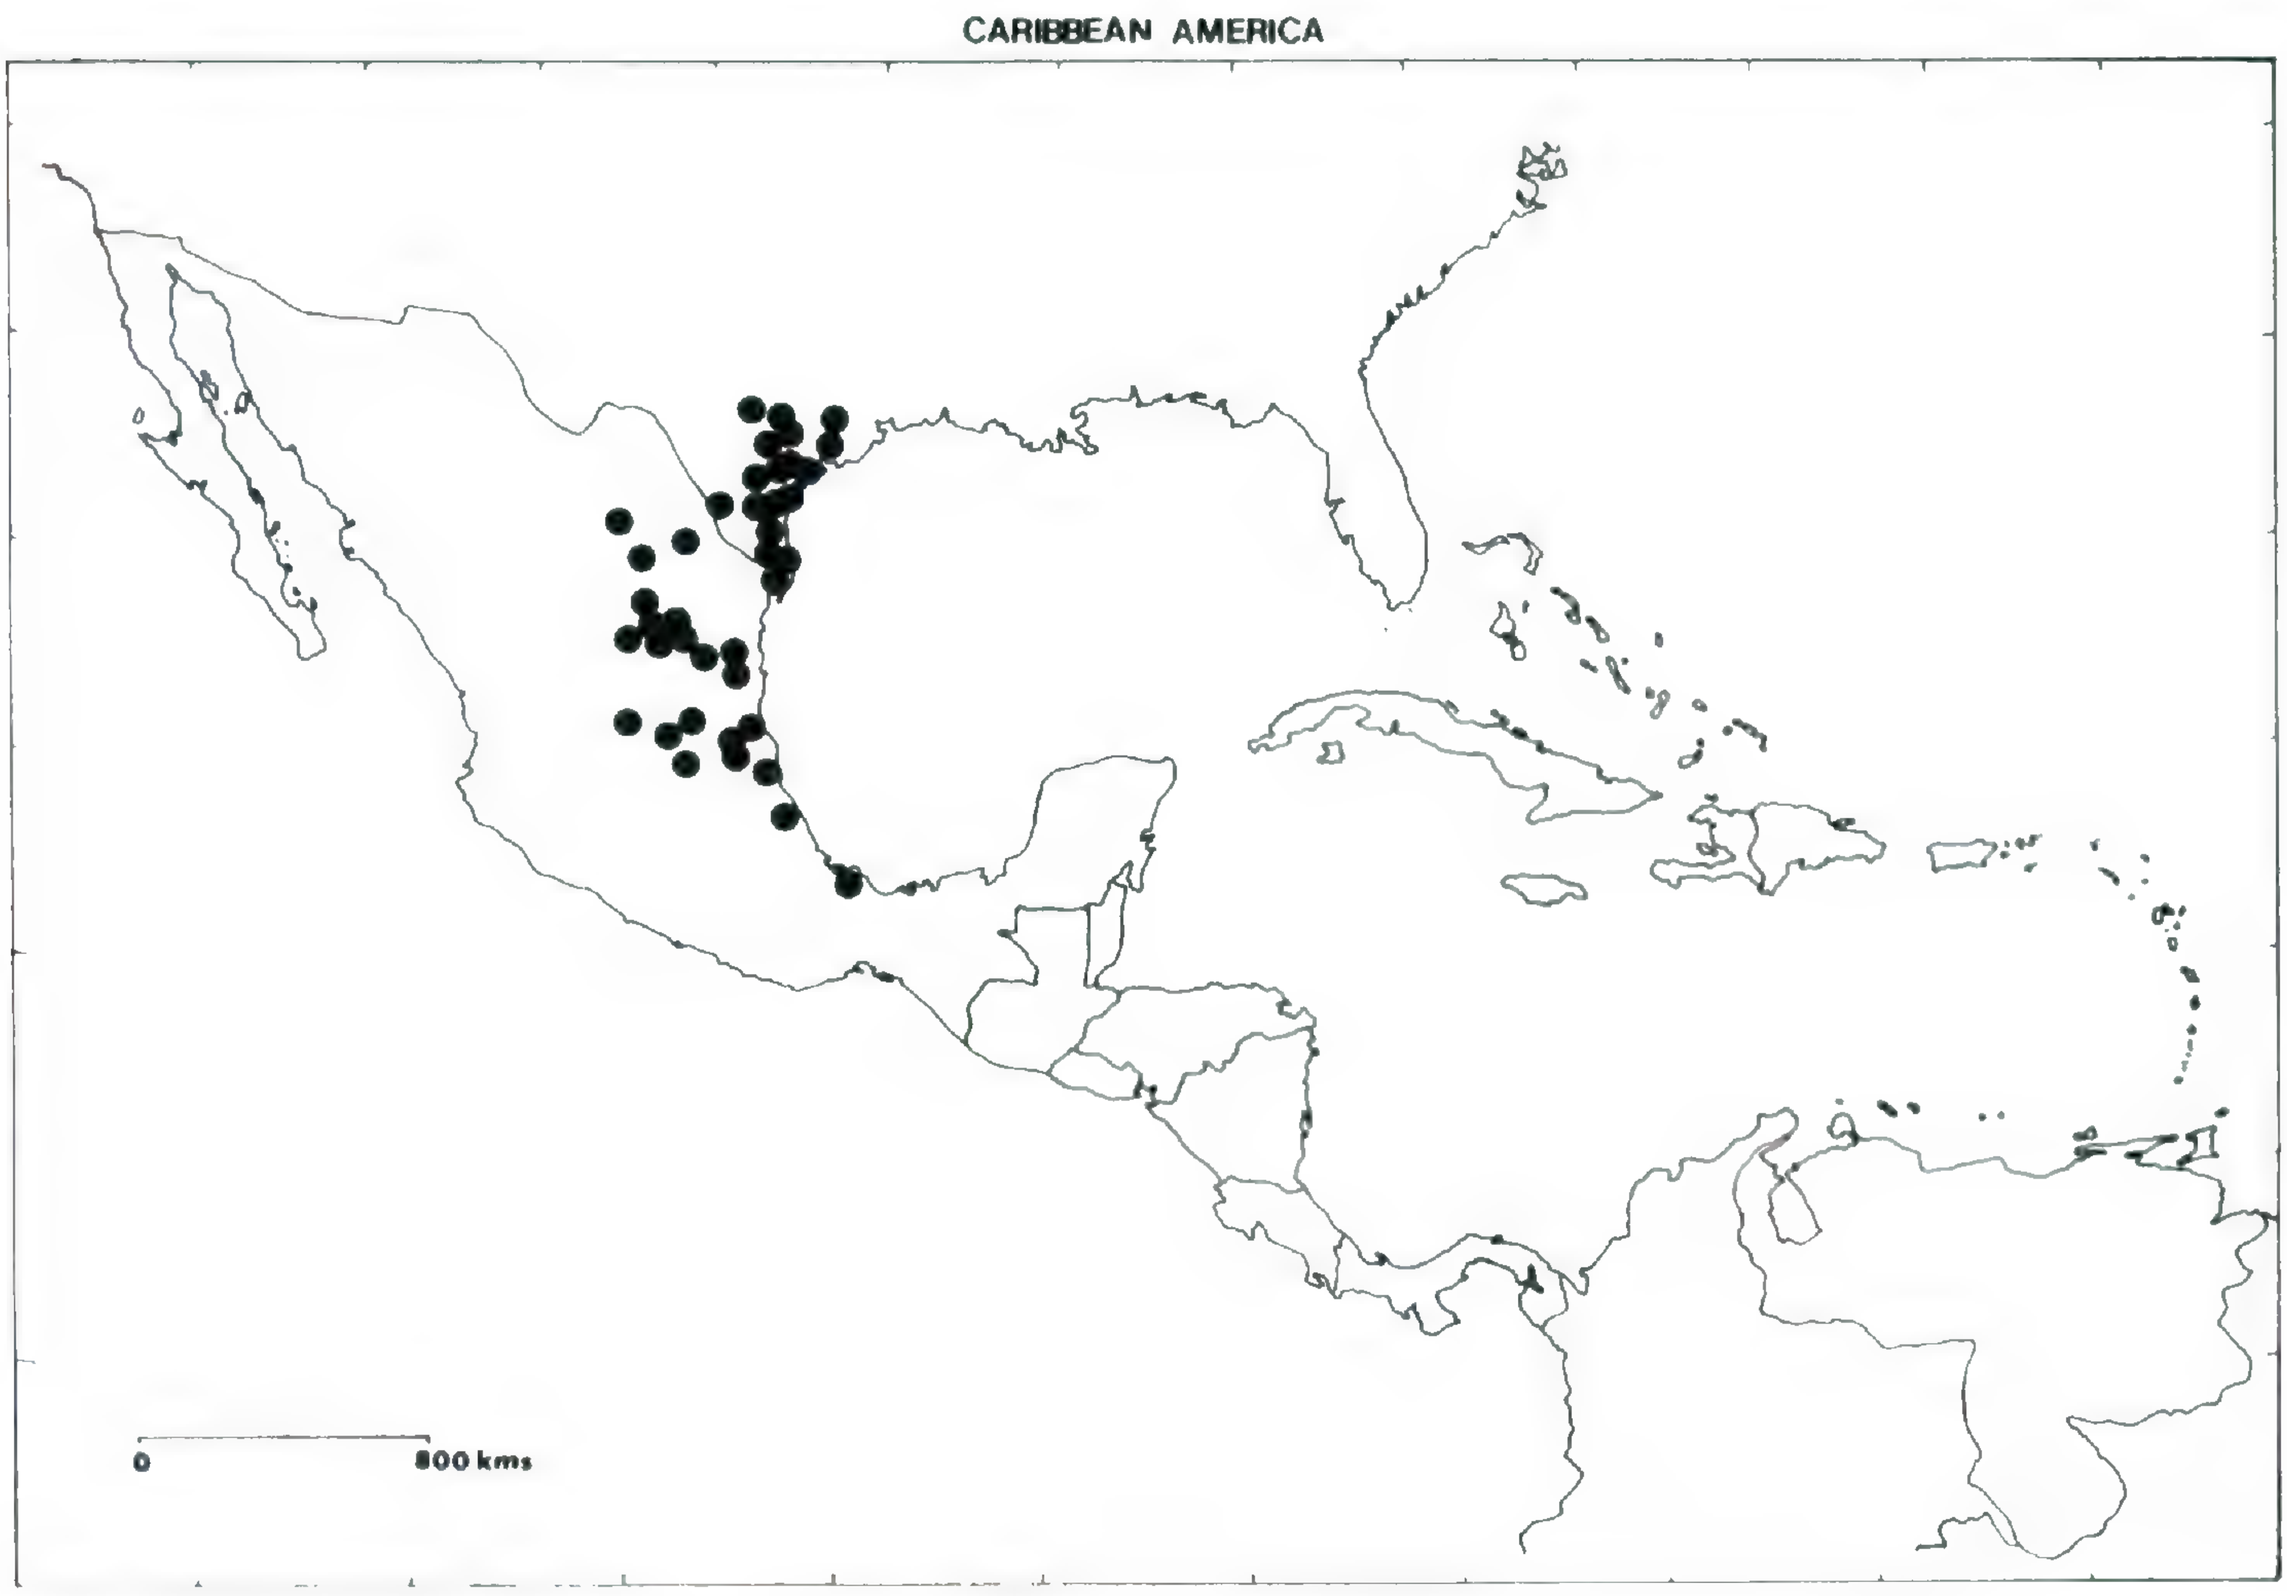


FIGURE 20. Distribution of *Ehretia anacua*.

Tamaulipas, Texas). Standley (1924) reported the wood to be used for wheel spokes, axes, tool handles, and yokes.

Ehretia latifolia DC., Prodr. 9: 503. 1845. TYPE: herb. amat. (holotype, G-DC, not seen; microfiche, MO).

Ehretia mexicana S. Watson, Proc. Amer. Acad. 26: 144. 1891. TYPE: Mexico. Jalisco: base of mountains near Lake Chapala, *C. G. Pringle 3085* (lectotype, GH, here designated; isolectotypes, BH, BM, F, G, GH, K, L, LE, MO, NY—2 sheets, UC, US—2 sheets). There are two collections at GH, neither annotated as holotype by Watson.

Ehretia luxiana J. D. Smith, Bot. Gaz. 18: 5. 1893. TYPE: Guatemala. Quiche: San Miguel Uspanlán, 6,000 ft., Apr. 1892, *Heyde & Lux 3065* (holotype, US 944452; isotypes, F, G, GH, K, MO, NY, P).

Ehretia cordifolia Robinson, Proc. Amer. Acad. Arts 29: 319. 1894; Pringle in Gard. and Forest 8: 153. 1894. TYPE: Mexico. Jalisco: valley, Zapotlán, 19 May 1893, *C. G. Pringle 4382* (holotype, F 106011; isotypes, A, BM, G, GH, K, LE, MO, NY, P, UC, US—2 sheets).

Ehretia viscosa Fernald, in Sargent, Trees and Shrubs 1: 25, pl. 13. 1902. TYPE: Mexico. Morelos: near Cuernavaca, 29 May 1899, *C. G. Pringle 7777* (lectotype, F 120287, here designated; isolectotypes, BH, GH, K, MEXU—2 sheets, MO, NY, UC). In describing this species, Fernald cited three collections. The order in which these are cited and his mention of them in his discussion indicates that he felt that the first one was the type collection.

Ehretia tehuacana Greenman, Publ. Field Mus. Nat. Hist. Chicago, Bot. 2: 339. 1912. TYPE: Mexico. Puebla: Las Mohoneras, Tehuacán, 2,200 m, *C. Conzatti 2220* (holotype, F 235156; isotype, GH).

Ehretia austinsmithii Standley, Publ. Field Mus. Nat. Hist., Chicago, Bot. Ser., 18: 984. 1938. TYPE: Costa Rica. Alajuela: Zarcero, 1,850 m, *Austin-Smith H528* (holotype, F 919653; isotypes, F, MO).

Tree to 15(–25) m tall, the trunk fluted, the twigs pubescent or shortly hirsute to nearly glabrous. Leaves persistent; petioles (3–)6–20(–31) mm long, puberulent or strigillose to nearly glabrous, narrowly canaliculate adaxially; leaf blades ovate to lanceolate or elliptic, (5.5–)7–12(–17) cm long, (2–)3–6(–9.5) cm wide, the apex acute to acuminate, rarely obtuse, the base obtuse or less commonly acute or slightly cordate, the margin serrate, rarely minutely so, adaxially scabrous to strigillose, abaxially coarsely to minutely puberulent or strigillose, occasionally nearly glabrous with only a few hairs on the major veins, the lateral veins 5–7. Inflorescence terminal or subterminal, a dense panicle, 4.5–7 cm long, (2–)3–5 cm broad, the branches puberulent to nearly glabrous. Flowers bisexual, monomorphic, sessile or short-pedicellate; calyx 1.6–2.6 mm long, glabrous to strigillose on the outer surface, sparsely to evenly ciliate along the interior margin, the 5 lobes deltate to triangular, 0.7–1 mm long; corolla white, 3.2–6 mm long, tubular with 5 reflexed, broadly ovate lobes 1.8–2 mm long and 1.6–2 mm wide, the tube 2.5–3 mm long; stamens 5, the filaments 4–4.5 mm long, the upper 2.5–3.2 mm free, glabrous, anthers ellipsoid, 1–1.5 mm long; ovary ovoid, 1.3–1.5 mm tall, 1 mm broad, disc not evident, style 3–4 mm long, faintly bilobed, the stigmas capitate. Fruits drupaceous, white, glabrous, broadly ellipsoid, 7–10 mm long, 6–9 mm wide, the endocarp remaining entire, 4-locular, only lightly ridged on the outer surface.

Distribution. *Ehretia latifolia* occurs from

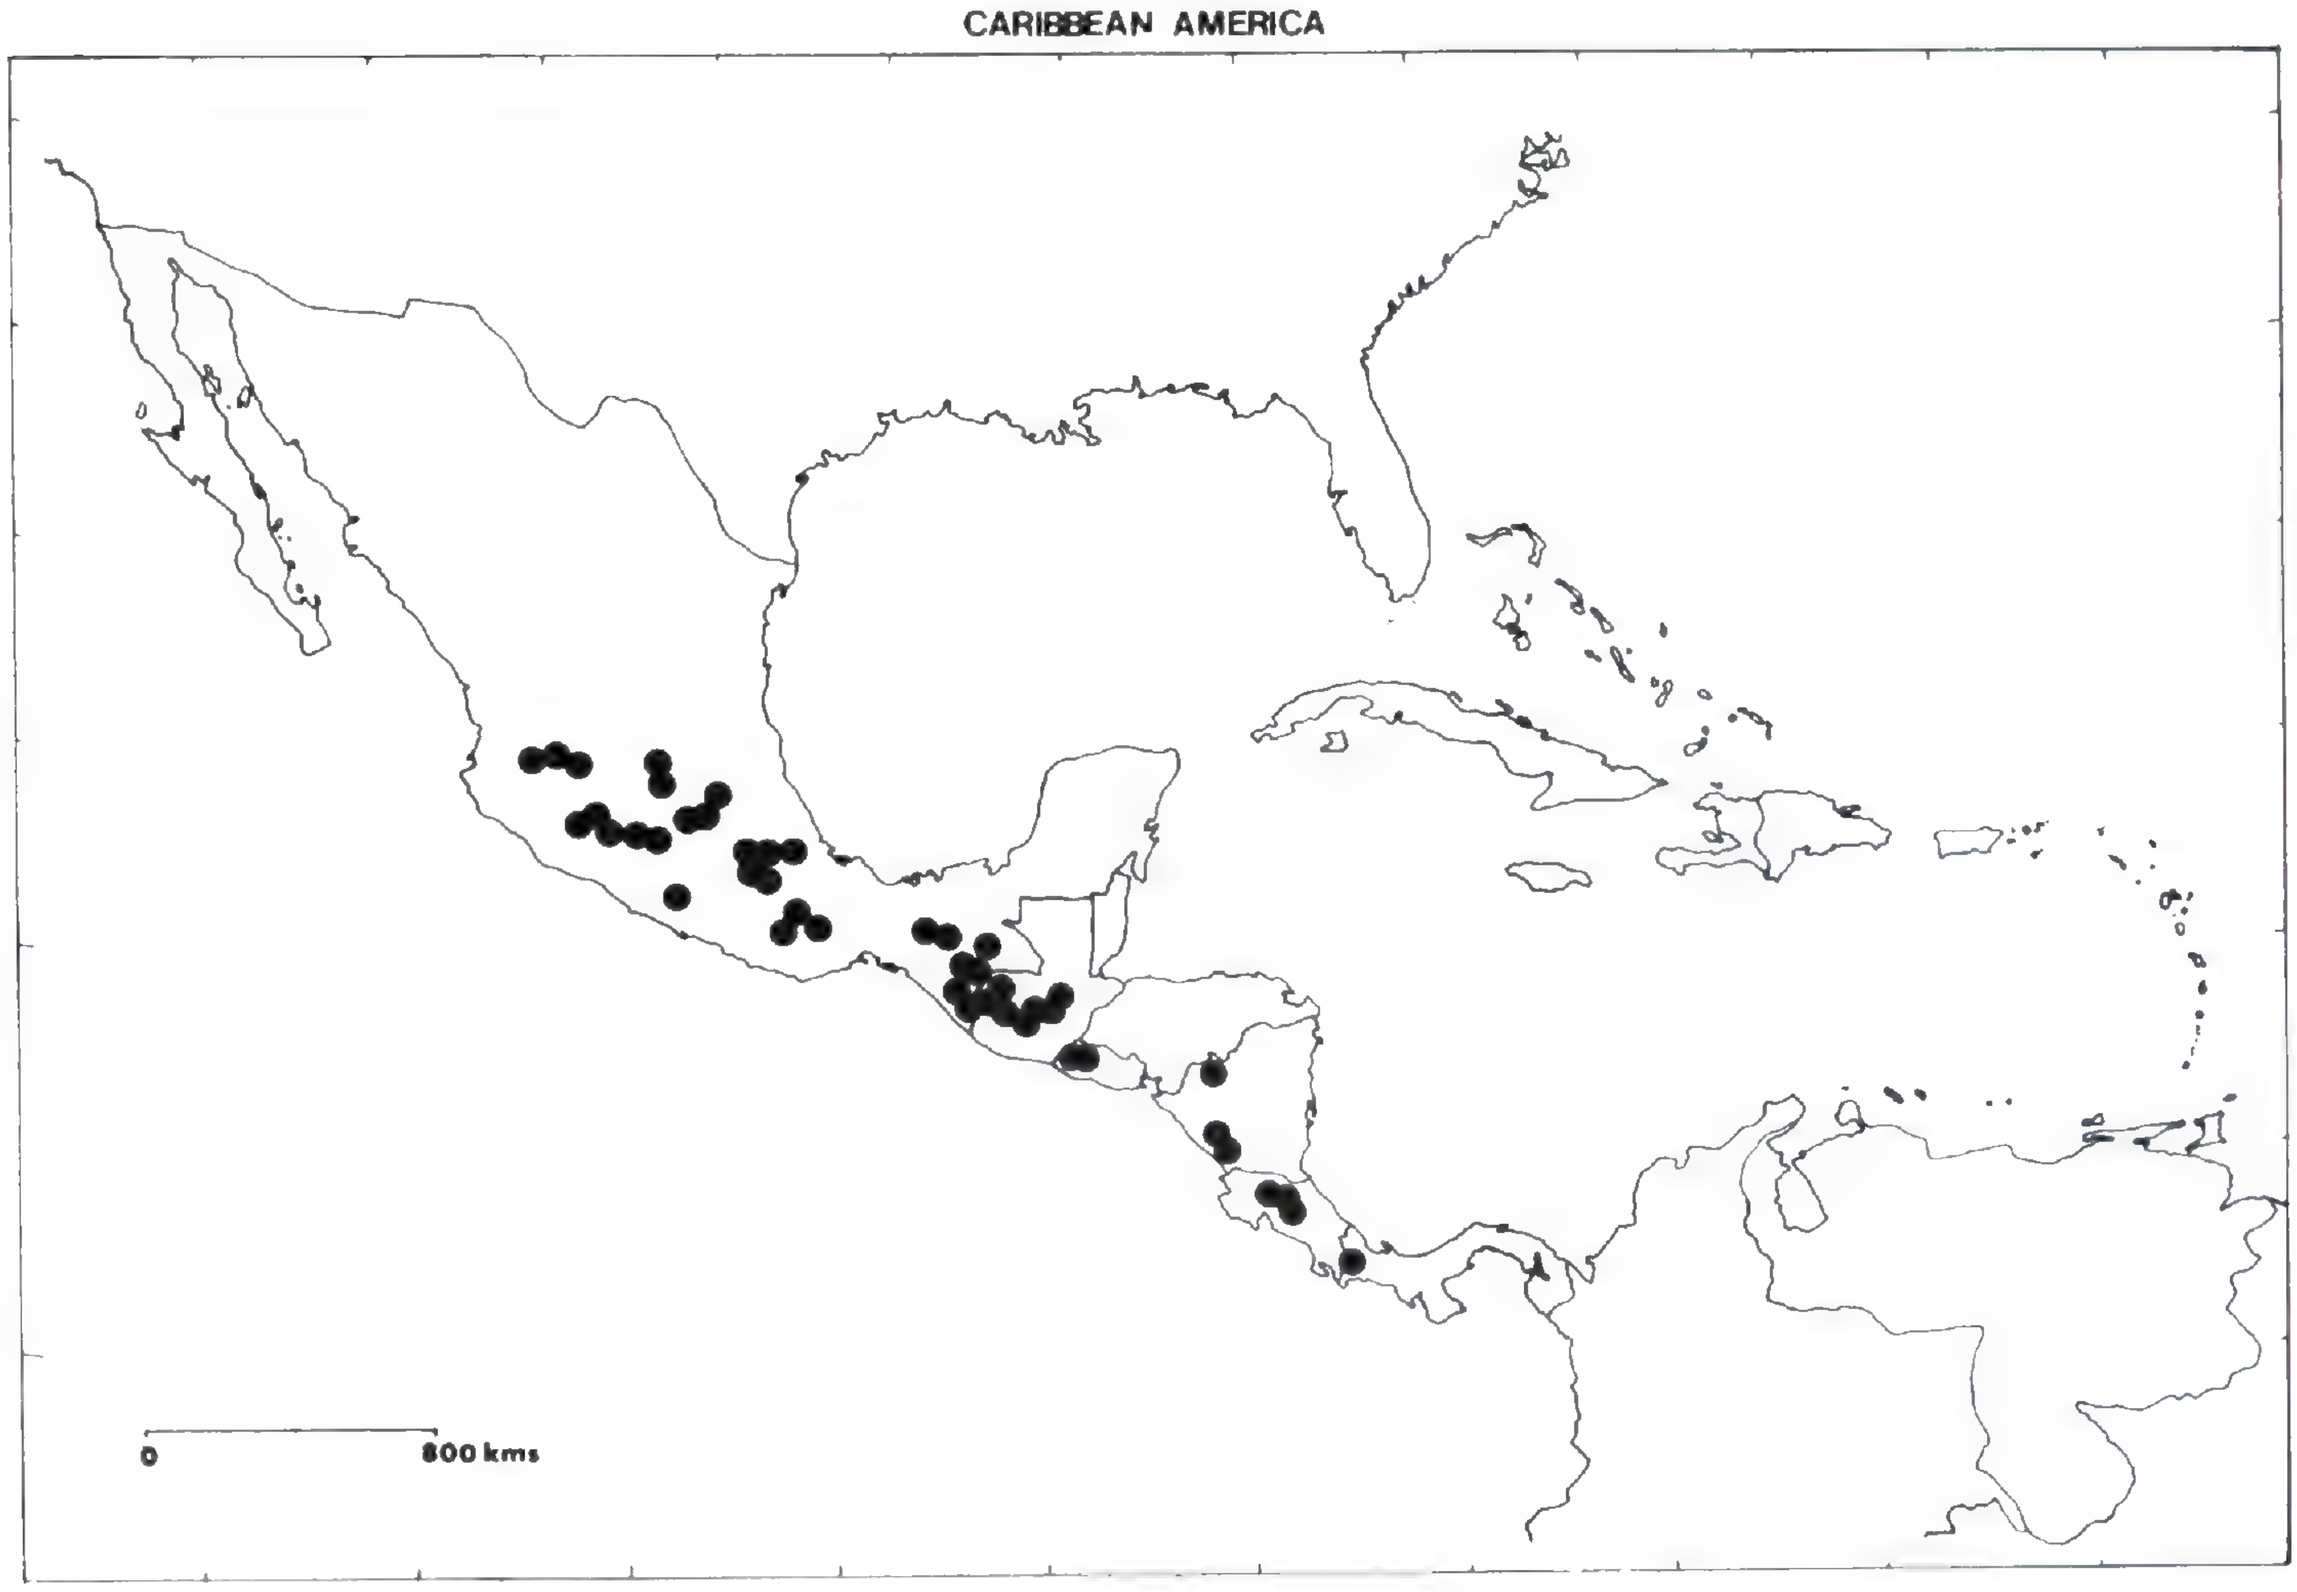

FIGURE 21. Distribution of *Ehretia latifolia*.

Jalisco in western Mexico through Central America to Chiriquí Province in Panama in cloud forests and dry montane forests at (1,500–)1,800–2,300 m (Fig. 21).

Ehretia latifolia exhibits extreme variability in leaf shape and indument, which has bred confusion. Standley (1924, 1938) recognized six species with serrate leaves in the New World. With the exception of *E. tehuacana*, all were based on characters of leaf shape and indument. When Watson (1891) published *E. mexicana*, he made no mention of how it differed from *E. latifolia*. The types of the two are nearly identical, and Standley (1924) reduced *E. mexicana* to synonymy. Smith (1893) published *E. luxiana* based on a collection from Guatemala with broader leaves that was almost glabrous abaxially and supposedly had larger flowers. The populations from the southern portion of the range do have slightly broader leaves that more often tend toward abaxial glabrousness, but there are many exceptions and there is no clear geographic discontinuity. At the time that Robinson (1894) published *E. cordifolia* it appeared distinct in having cordate leaf bases. However, field studies (discussed below) indicate that this is not a valid character since it varies on single individuals as well as within populations.

The problem with *Ehretia viscosa*, a species supposedly distinct in having glandular hairs, is slightly more complex. The few collections of it differ only in the possession of glandular hairs and in all other respects are identical to *E. latifolia*. Further, they come from localities scattered throughout the Mexican range of *E. latifolia*. Glandular hairs thus appear to be an infrequently expressed trait rather than a monophyletic group that should be recognized as a species.

Standley (1924) differentiated *Ehretia tehuacana* by its corollas about 10 mm long (supposedly more than 3 mm longer than the other species he recognized). None of the corollas on the type collection exceed 6 mm (Standley must have based his distinction on Greenman's original description) and are within the normal range of variation for *E. latifolia*. At the time that Standley (1938) described *E. austinsmithii*, it appeared to be geographically disjunct with the nearest population to the north in Guatemala. As currently defined, *E. latifolia* has a relatively continuous distribution in Central America, being unknown only in Honduras. The Central American populations are quite uni-

TABLE 3. Populations of *Ehretia latifolia* sampled for variation in leaf shape and indument.

Population	State	Voucher numbers	Elevations	Numbers of individuals sampled
Volcan Tacaná	Chiapas	2667–2670	2,300 m	4
Benito Juarez	Chiapas	2690–2695	2,100 m	5
Union Juarez	Chiapas	2721	2,010 m	1

Monte Albán	Oaxaca	2817–2823	1,800 m	5
Acatzingo	Puebla	2957	1,960 m	1
Chapulco	Puebla	2960–2962	2,000 m	3
Ciudad Mendoza	Veracruz	2971–2975	2,000 m	5
Ixthuatlancillo	Veracruz	2992–2993	1,500 m	2
Tepoztlán	Morelos	2996–2998	1,700 m	3
Campo Morado	Guerrero	2888–2892	1,400 m	5
Querendaro	Michoacan	3059–3063	1,870 m	5
Tiripitio	Michoacan	3064–3068	2,040 m	5

form while most of the significant variation appears in Mexico.

FIELD STUDIES OF VARIATION OF LEAF MORPHOLOGY

The numerous synonyms of *Ehretia latifolia* seem to have arisen via a paucity of collections and a failure to understand how leaf shape and indument vary on individual plants, within populations, and between populations. Herbarium specimens are only limited samples of individual trees and seldom provide an adequate representation of variation of leaf morphology. In order to assess how leaf morphology varied on a single individual, within populations, between populations, and over the developmental life span of individual leaves, collections were made over the range of *E. latifolia* in Mexico.

Some variation emerges during the ontogeny of an individual leaf (discussed earlier under leaf morphology) and a small portion correlates with geography, but most variation appears random and often can be found within a single population.

Two characters seem to vary geographically. Plants from Central America and part of adjacent Chiapas tend toward slightly broad, abaxially nearly glabrous leaves, while plants from populations further north have narrower, abaxially pubescent leaves. However, other collections from Central America have leaves puberulent below, and such leaves are found over a long geographic distance with no clear discontinuity. Trends of this sort occur in other woody Boraginaceae, for example, *Cordia curassavica* (Jacq.) Roemer & Schultes (Miller, 1985), and are perhaps a result of a more pronounced dry season than occurs to the north in parts of Mexico. In *Cordia curassavica* much of the variation disappears in plants raised in the greenhouse (Miller, 1985).

The second geographically correlated variation is that plants from the Tehuacán Valley in Puebla, Mexico, have leaves with smaller than usual serrations on the margin. This extreme of variation is not even consistent within Puebla and is not considered worthy of taxonomic recognition.

Most variation in leaf morphology appears random, varying in form and indument on individuals and within populations. Five leaves from five individuals (in some cases five individuals could not be found) in each population from various parts of the distributional range in Mexico were measured for length, width, length/width ratio, broadest point (calculated as distance from broadest point of the leaf to the base divided by total leaf length), apical angle, and basal angle (Tables 3, 4). In addition the indument on the adaxial and abaxial leaf surfaces was noted. The leaves selected were at least three nodes below the apex of the shoot to avoid immature leaves and never adjacent to a branch, as these are often quite different in form.

Field studies reveal considerable variation in leaf shape on a single tree, with leaf bases often varying from acute to obtuse and sometimes even cordate

TABLE 4. Variation in leaf shape among Mexican populations of *Ehretia latifolia*. Upper figures are means and lower figures are standard deviations.

Population	Leaf length/ width ratio	Broadest point of leaf	Apical angle	Basal angle
Volcán Tacaná	2.13	0.44	73.75	109.25
	0.33	0.059	18.50	32.14

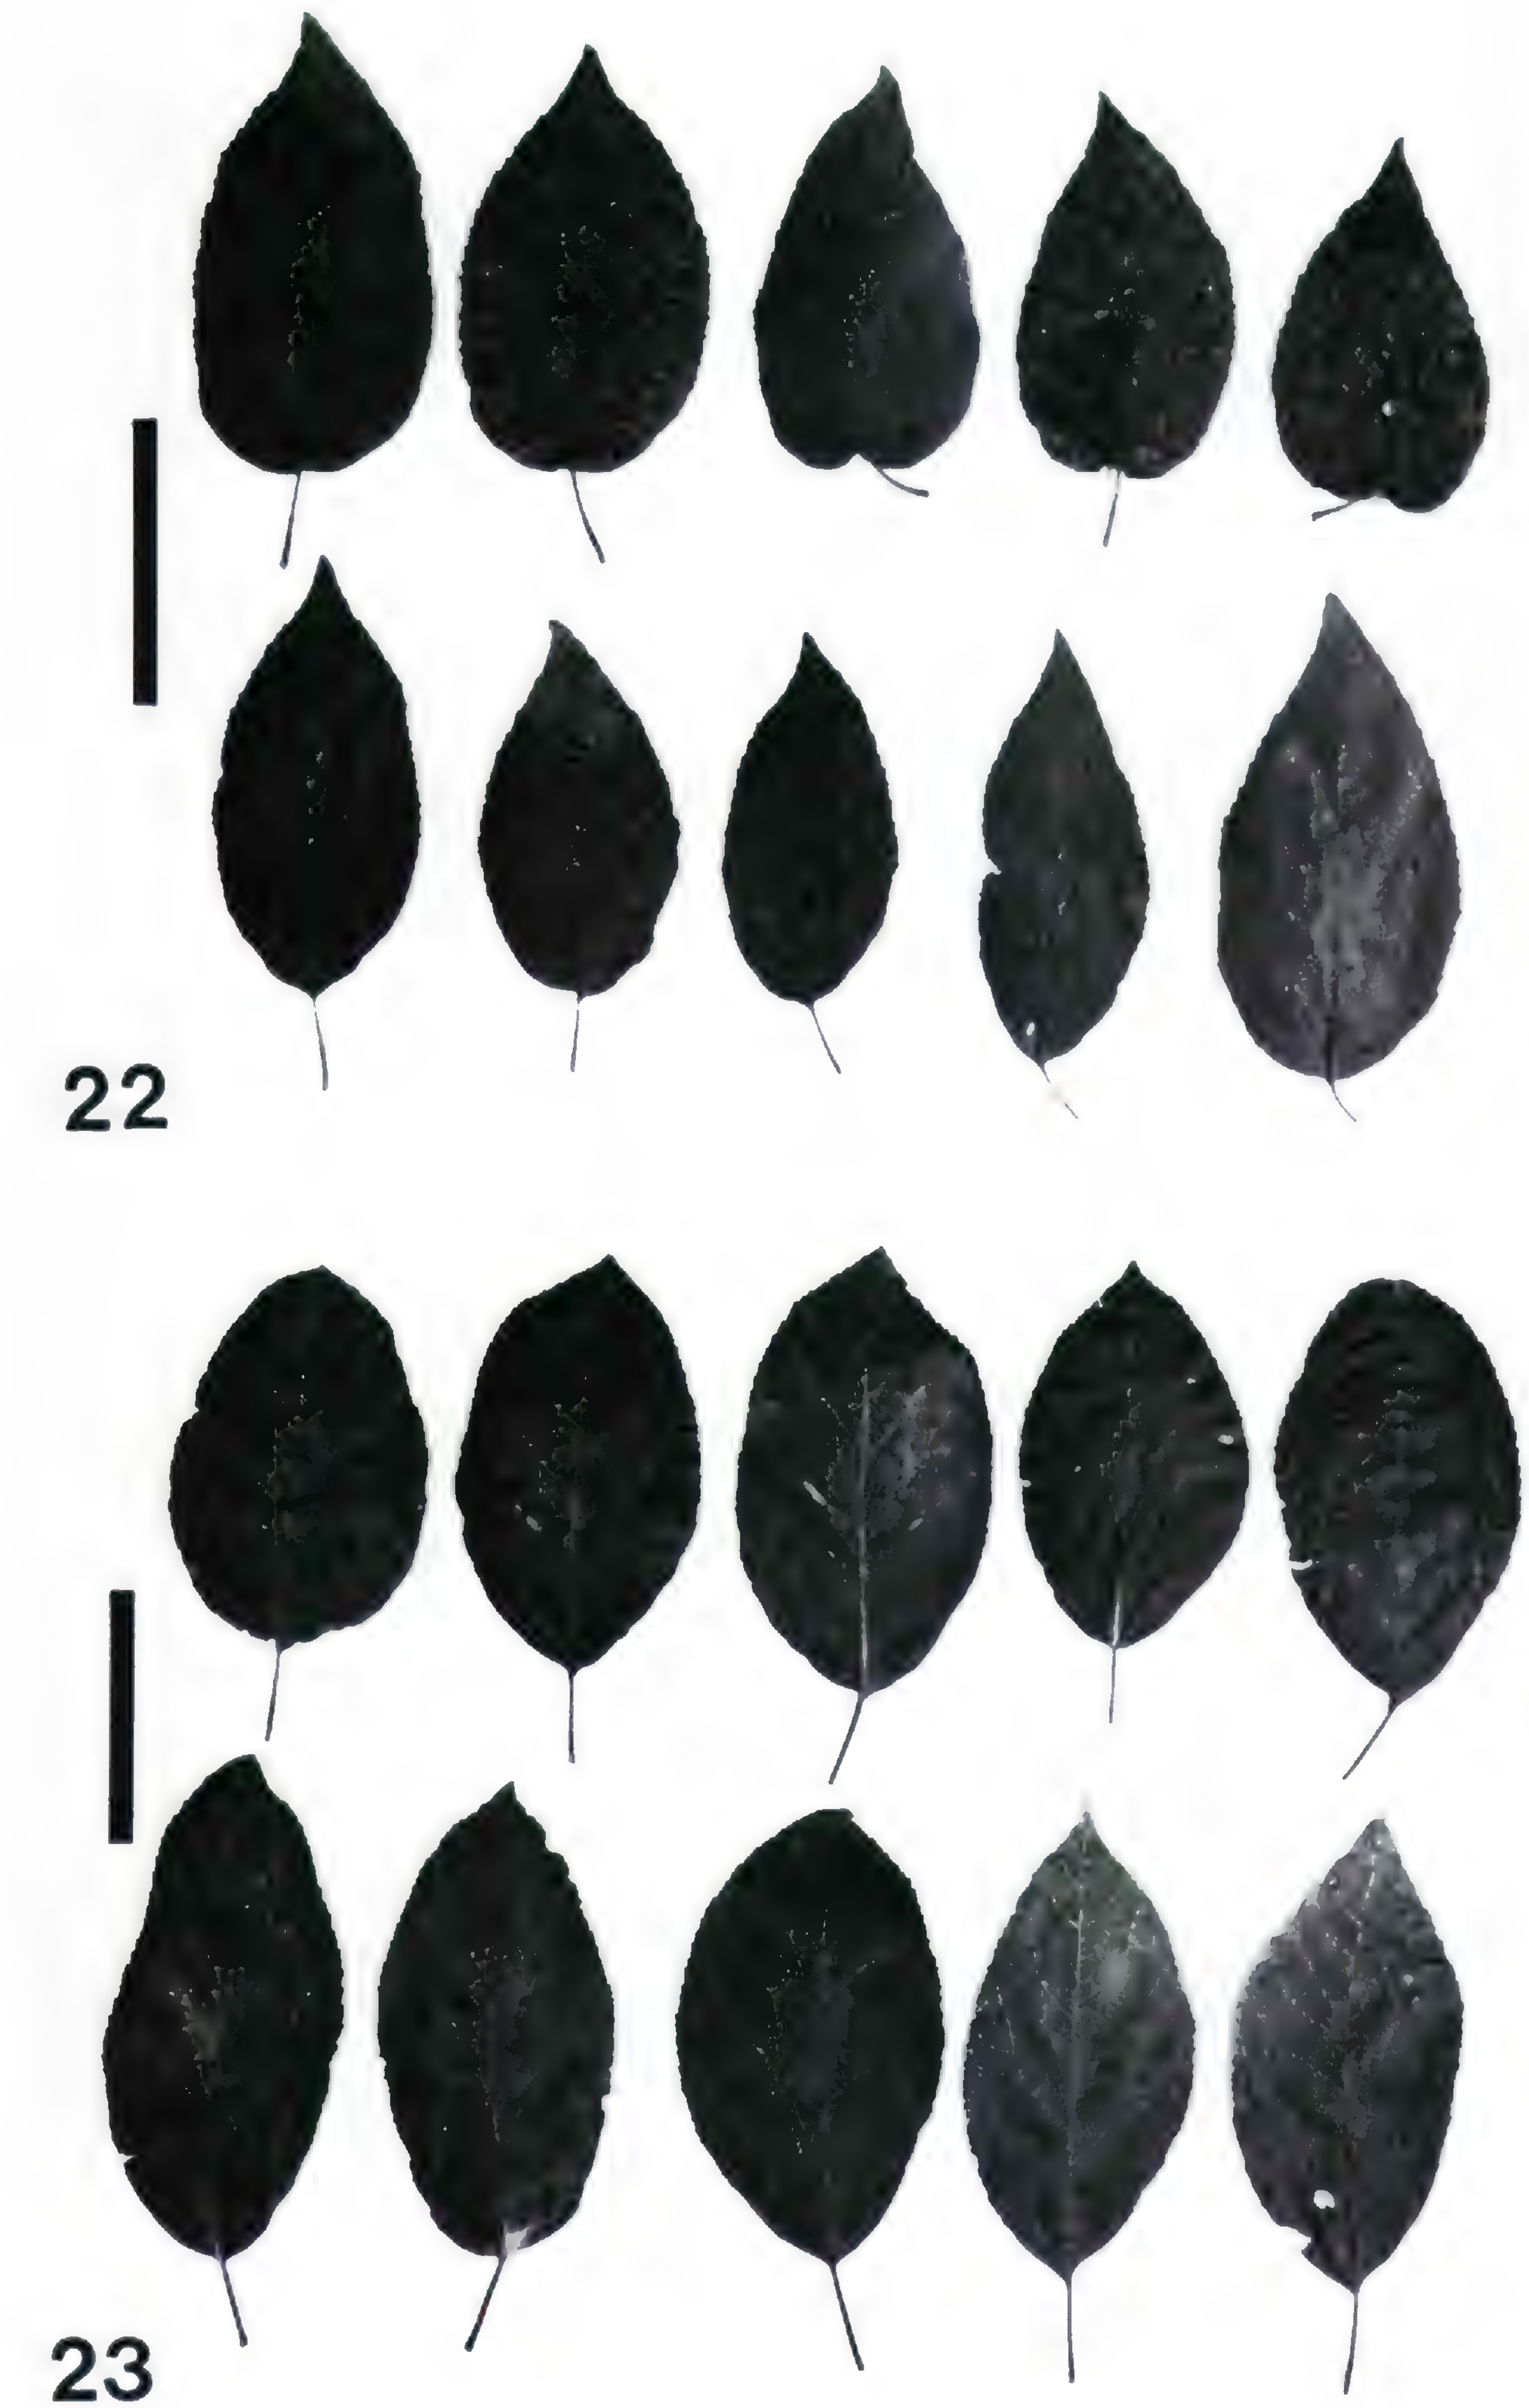
Ciudad Mendoza	2.46	0.44	57.80	109.60
	0.46	0.045	18.44	33.52
Ixthuatlancillo	1.97	0.44	71.50	105.00
	0.25	0.060	14.67	28.28
Tepoztlán	2.08	0.46	66.67	97.67
	0.22	0.078	8.88	15.37
Campo Morado	1.97	0.43	75.80	119.40
	0.29	0.054	21.10	28.12
Querendaro	1.93	0.39	67.40	143.40
	0.25	0.041	15.24	18.91
Tiripitio	2.07	0.39	56.20	162.00
	0.31	0.055	8.40	33.88

from one branch to another. Shape of the leaf base was the character used to distinguish *Ehretia cordifolia*, but examination of leaves from different branches of a single tree collected near Guelatao, Oaxaco, Mexico (Fig. 22) shows this character to vary on a single individual. The same type of variation in shape of leaf apices often occurs on single individuals, as exemplified by leaves from different branches of an individual collected near Motozintla, Chiapas, Mexico (Fig. 23).

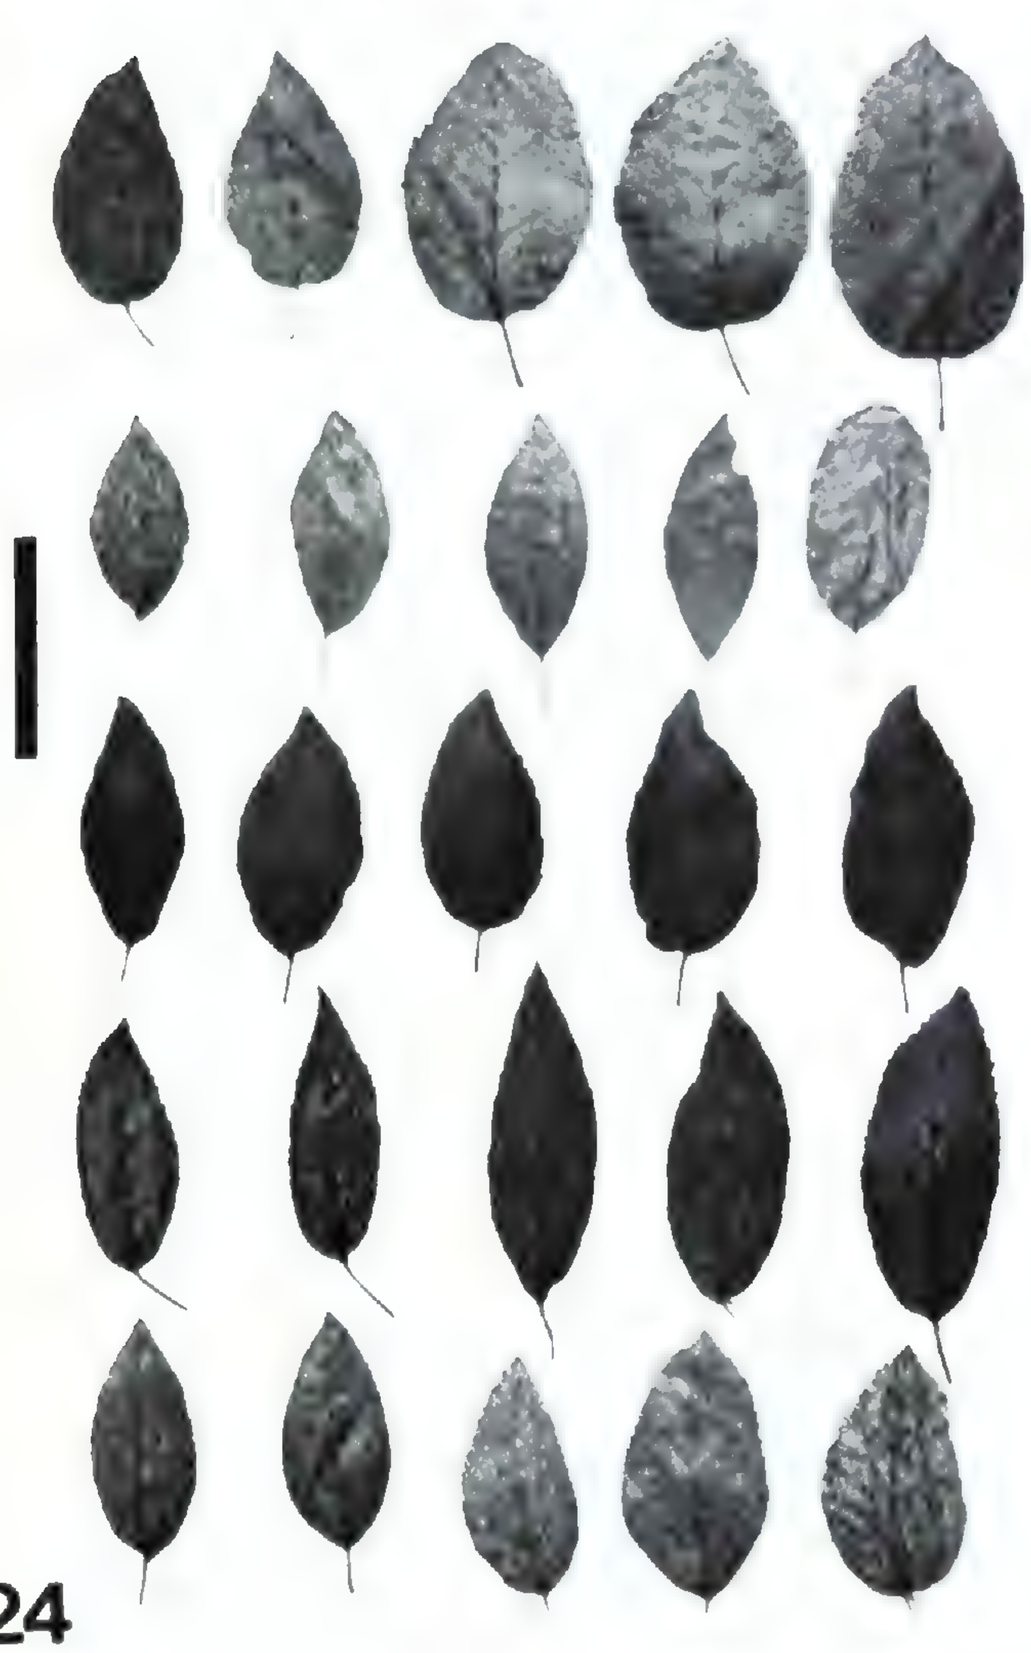
Most of the Mexican populations examined were relatively constant in terms of leaf indument, although occasional plants were more or less pubescent than surrounding individuals. There did appear to be, however, a significant amount of variation in leaf shape among individuals from a single population. Leaves from the population at Monte Alban (Fig. 24) ranged from 1.5 to 3.2 in leaf length/width ratio and 45° to 100° in apical angle. The sampled population near Ciudad Mendoza (Fig. 25) had leaf length/width ratios of 1.7 to 3.4 and a range of 60° to 240° in basal angle. If this degree of variation can be found in a single population, leaf apex, blade, and base shape are not reliable characters for delimiting species.

Mean values and standard deviation are given for characters of leaves from Mexican populations of *Ehretia latifolia* in Table 4. Leaf length/width ratio, broadest point, apical angle, and basal angle appear to be the best measures of overall leaf shape.



22

23



24

25

FIGURES 24, 25. Variation in leaf shape among five individuals from single populations of *Ehretia latifolia*. Each row consists of five leaves from a single individual.—24. From top to bottom, *Miller & Myers 2817–2821* (MO).—25. From top to bottom, *Miller & Torres 2971–2975* (MO). Scale bars equal 5 cm.

Variation in leaf morphology among populations is overlapping in range, and no clear geographic patterns appear.

Representative specimens examined. MEXICO. HEREDIA: along road N of Gethsemini de Heredia, 1,500–1,700 m, *Hartshorn 1208* (CR, F, MO); en depresión al Oeste del Monte de la Cruz, San Rafael, 1,700 m, *Jiménez 2513* (F). PUNTARENAS: Monteverde, lower community, 1,450 m, *Haber 203* (CR, MO); Santa Elena, 5 km W of Santa Elena on road to highway, *Haber 1775* (MO); Monte Verde, along Río Guacimal below Lechería, 1,500 m, *Hammel & Trainer 13837* (MO). SAN JOSÉ: Tres Ríos, *Córdoba 317* (CR); vicinity of Santa María de Dota, 1,500–1,800 m, *Standley & Valerio 44145* (US). PANAMA. CHIRIQUÍ: a lo largo del camino que va de Bambito a los llanos de lava, 6,000 ft., *Correa & Lazor 1410* (F, MO); at opening to canyon to Bambito, 5,000 ft., *Tyson 5870* (MO—2 sheets); Río Chiriquí Viejo valley, near Bambito, *P. White 220* (F, GH, MO).

Ehretia tinifolia L., Syst. Nat. ed. 10. 2: 936. 1759. TYPE: from Patrick Browne's Jamaican herbarium purchased by Linnaeus in 1758 (lectotype, here designated, LINN (Savage Catalog number 254.1); microfiche, MO; photo, F; isolectotype, BM).

Ehretia longifolia Miers, Ann. & Mag. Nat. Hist. Ser. IV. 3: 110. 1869. SYNTYPES & ISOSYNTYPES: In Antillis et Mexico, Jamaica, *in herb. Hook., Lane* (BM); Jamaica, *Macfadyen* (BM, K); Mexico, Oaxaca, Ravins a 3,000 ft., *Galeotti 7194* (G, K).

Ehretia sulcata Miers, Ann. & Mag. Nat. Hist. Ser. IV. 3: 109. 1869. SYNTYPES & ISOSYNTYPES: in Antillis, *herb. Mus. Brit.* (not identified); Jamaica, *herb. Sloan. Vol. vii. Fol. 5* (not identified); in hort. Kew. cult., Jamaica, *Houston* (BM); in herb. Hook., Jamaica, *Purdie* (BM); Cuba, *La Sagra* (K, LE); Cuba, Havana, *Greene* (BM, K).

Tree to 15(–25) m tall, the twigs essentially glabrous. Leaves persistent; petioles (3–)5–10(–14) mm long, glabrous canaliculate adaxially; leaf blades elliptic, (5–)6.5–12(–16.5) cm long, (2.5–)3–6(–8) cm wide, the apex obtuse to rounded, the base

obtuse to acute, the margin entire, adaxially glabrous and lustrous, abaxially glabrous, the lateral veins 6–7. Inflorescence terminal, paniculate, 7–15 cm long, the branches glabrous. Flowers bisexual, sessile or short-pedicellate; calyx campanulate, 1.5–2 mm long, the 5 lobes ovate, 1.5–2 mm long, 0.7–0.9 mm wide, glabrous externally, ciliate along the interior margin; corolla white, tubular-campanulate with 5 reflexed lobes, 4–4.6 mm long, glabrous on the exterior surface, the lobes widely oblong to oblong-ovate, 2.5–5 mm long, 1.3–1.7 mm wide, the tube 1.3–2.1 mm long; stamens 5, the filaments flattened, 3–4.5 mm long, the upper 2–3 mm free, glabrous, the anthers ellipsoid, 1–1.3 mm long; ovary ovoid to broadly ovoid, 1–1.2 mm long, 1 mm broad; style 2–3.4 mm long, divided for 0.5–0.7 mm, the stigmas truncate. Fruits drupaceous, yellow-orange, glabrous, broadly ellipsoid, 5–7 mm long, 4–6 mm broad, the endocarp dividing into 2, 2-locular pyrenes, these ridged-reticulate on the outer surface.

Distribution. *Ehretia tinifolia* occurs from southeastern Mexico to Honduras and on Cuba, Hispaniola, Jamaica, and the Cayman Islands in lowland, moist to wet forests from sea level to 600(–1,500) m (Fig. 26). Collections cited from Guerrero, Michoacán, Nayarit, San Luis Potosí, and Sinaloa are not included in the distribution map as they are presumed to be out of the natural range of the species and are probably from cultivated plants.

Ehretia tinifolia is distinguished from the other New World species by its glabrous, lustrous, entire-margined leaves and elongate, paniculate inflorescence. It is widely cultivated, even outside of its natural range for its attractive flowering and fruiting display and as a shade tree.

The two species described by Miers, *Ehretia longifolia* and *E. sulcata*, are both clearly synonymous from Miers's description and their West Indian distributions. Unfortunately, Miers cited specimens with little information and these collections remain difficult to identify. For this reason, these names have not been lectotypified, and syntypes are cited here.

Representative specimens examined. MEXICO. CAMPECHE: a 3 km al sur de la carretera Champotón–Campeche, sobre el camino a El Zapote, *Cabrera & Cabrera 2389* (MEXU, MO); sobre el camino a Pixoyal, a 30 km al norte de Escarcega, *Cabrera & Cabrera 2410* (MEXU); 5 km al sur de Constitución, a 70 km al este de Escarcega, *Cabrera & Canul 5063* (MEXU, MO); Rancho-Guadalupano, Mpio. Campeche, 12 m, *Chan & Flores 478* (F); Yohaltum, Mpio. Champoton, 12 m, *Flores & Chan 8715* (F); environs de Campeche, *Linden 107* (K); Campo Experimental, Escarcega, 100 m, *Marroquín 294* (WIS); 45 km al NE de Campeche, camino a Merida, 30 m, *Martínez et al. 3011* (BM, CAS, MEXU); cultivated in garden, *Seler 4016* (F); near Xujil, 300–400 m, *Shepherd 93* (LL, MICH—2 sheets, WIS—2 sheets); Hecelchakan, *Stewart 52* (GH). CHIAPAS: in the sitios or along the streets of Ocozocuautla, Mpio. of Ocozocoautla, 580 m, *Breedlove & McClintock 23514* (DS, MEXU, MO); along the streets or in the sitios of Tonala, Mpio. Tonala, *Breedlove & Thorne 30658* (B, DS, F, LL, MEXU, MICH, MO, NY); cultivated, dry open slope with tropical deciduous forest, 32 km NNW of Soyalo, along the road to Copainala above Chicoasen, Mpio. of Chicoasen, 450 m, *Breedlove 34039* (DS, MEXU, MO); Mpio. of Cintalapa, 23 km W of Las Cruces along the road to La Mina microwave station, 870 m, *Breedlove & Davidse 54141* (CAS, MO, NY); Chiapa de Corzo, Mpio.. of Chiapa de Corzo, *Laughlin 794* (DS, F, LL); Margaritas, Comitán, 1,530 m, *Matuda 5783* (LL, MEXU, MICH, MO), *15783* (F); Escuintla, cultivated, *Matuda 16607* (F, MEXU); Paderón, Tonala, *Matuda 16951* (F—2 sheets, MEXU); Encañana, arriba Chancona, N Tuxtla Gutierrez, *Miranda 5263* (MEXU, US); on plaza at Chiapa, *Souviron & Erlanson 103* (US). GUERRERO: Iguala, highway 95, La Cabaña Motel, cultivated, *Freeland & Spetzman 33* (MEXU—2 sheets); Motel "Costa Azul," cultivated, *Lorence & Lorence 3511* (CAS, MEXU, MO); along Mexican highway 95 at Tierra Colorado, ca. 800 m, *Miller & Campos 2954* (MEXU, MO); Jardín Botánico, Chilpancingo, 1,300 m, cultivated, *Toledo & Blanco 50* (MEXU). MICHOACAN: 1 km S of Nueva Italia along Mexican highway 37, cultivated at gas company, ca. 200 m, *Miller & Téllez 3079* (MEXU, MO). MORELOS: Colonia López Mateos, Mpio. Tepalzingo, 1,100 m, *Guerrero et al. 1477* (MEXU); Barranca Honda, Mpio. Tlaltizapan, 1,050 m, *Gutiérrez M. 254* (MEXU); Yautepec, alrededores del poblado Ignacio Bastidas, 1,520 m, *Muskus 40* (MICH); Cuernavaca, carretera a Acapulco, *Palacios s.n.* (DS, MICH, WIS); Villa de Ayala, 1,260 m, *Palacios s.n.* (MEXU); Mpio. Yautepec, Ignacio Bastidas, 1,520 m, *Valdez 43* (CAS). NAYARIT: Acaponeta, *Martínez 7* (F); Las Isletas, 5 km E of San Blas on the road to Miramar, sea level, *Miller & Téllez 3194* (MEXU, MO). OAXACA: Union Hidalgo, *Bailey 572* (BH, MICH); Puerto Escondido, *Boege 2642* (GH, MEXU); Pinotepa Nacional, *Boege 2660* (MEXU); Cuicatlán, *Conzatti & Gonzalez 38* (MEXU); along highway 125 between Pinotepa Nacional and Tlaxiaco between the towns of Coxcatitlán and San Sebastian Ixcapa, 280 m, *Croat 45768* (MO, WIS); Oaxaca, *Davis & Johnston s.n.* (TEX); Cuicatlán, 1,600 ft., *González 38* (GH); El Carrizal, a 2 km al SW del Morro de Mazatlán, o sea a 35 km al SW de Salina Cruz, sobre la carretera a Pochutla, Mpio. de Tehuantepec, *González 473* (MEXU, TEX); Ixtalpec, *Mell 2145* (NY, US); Oaxaca, park in town, 1,600 m, cultivated, *Miller & Myers 2824* (MEXU, MO); cerca y a S de Cuicatlán, *Miranda 4544* (MEXU—3 sheets); Tlacolula, 1,600 m, *Palacios s.n.* (DS); Cuicatlán, 2,000 ft., *Pringle 5790* (GH, MEXU, US); Pochutla, 100 m, *Reko 3305* (US); Huatulco, 150 m, *Reko 6004* (F); Cuicatlán, *Rusby 74* (NY—2 sheets, US); Cacahuatepec, cultivated in Panla, *Sousa et al. 5216* (CAS, US); Salina Cruz, 0–300 m, *Williams 9736* (F, GH). QUINTANA ROO: en la brecha de Divorciados a la Pantera, por la via corta a Mérida, *Cabrera & Alvarez 1678* (BM, MEXU—2 sheets); a 1 km al W de Ciudad Vallarta, sobre el camino a Leona Vicario, *Cabrera et al. 2577* (MO); a 14 km al NW de

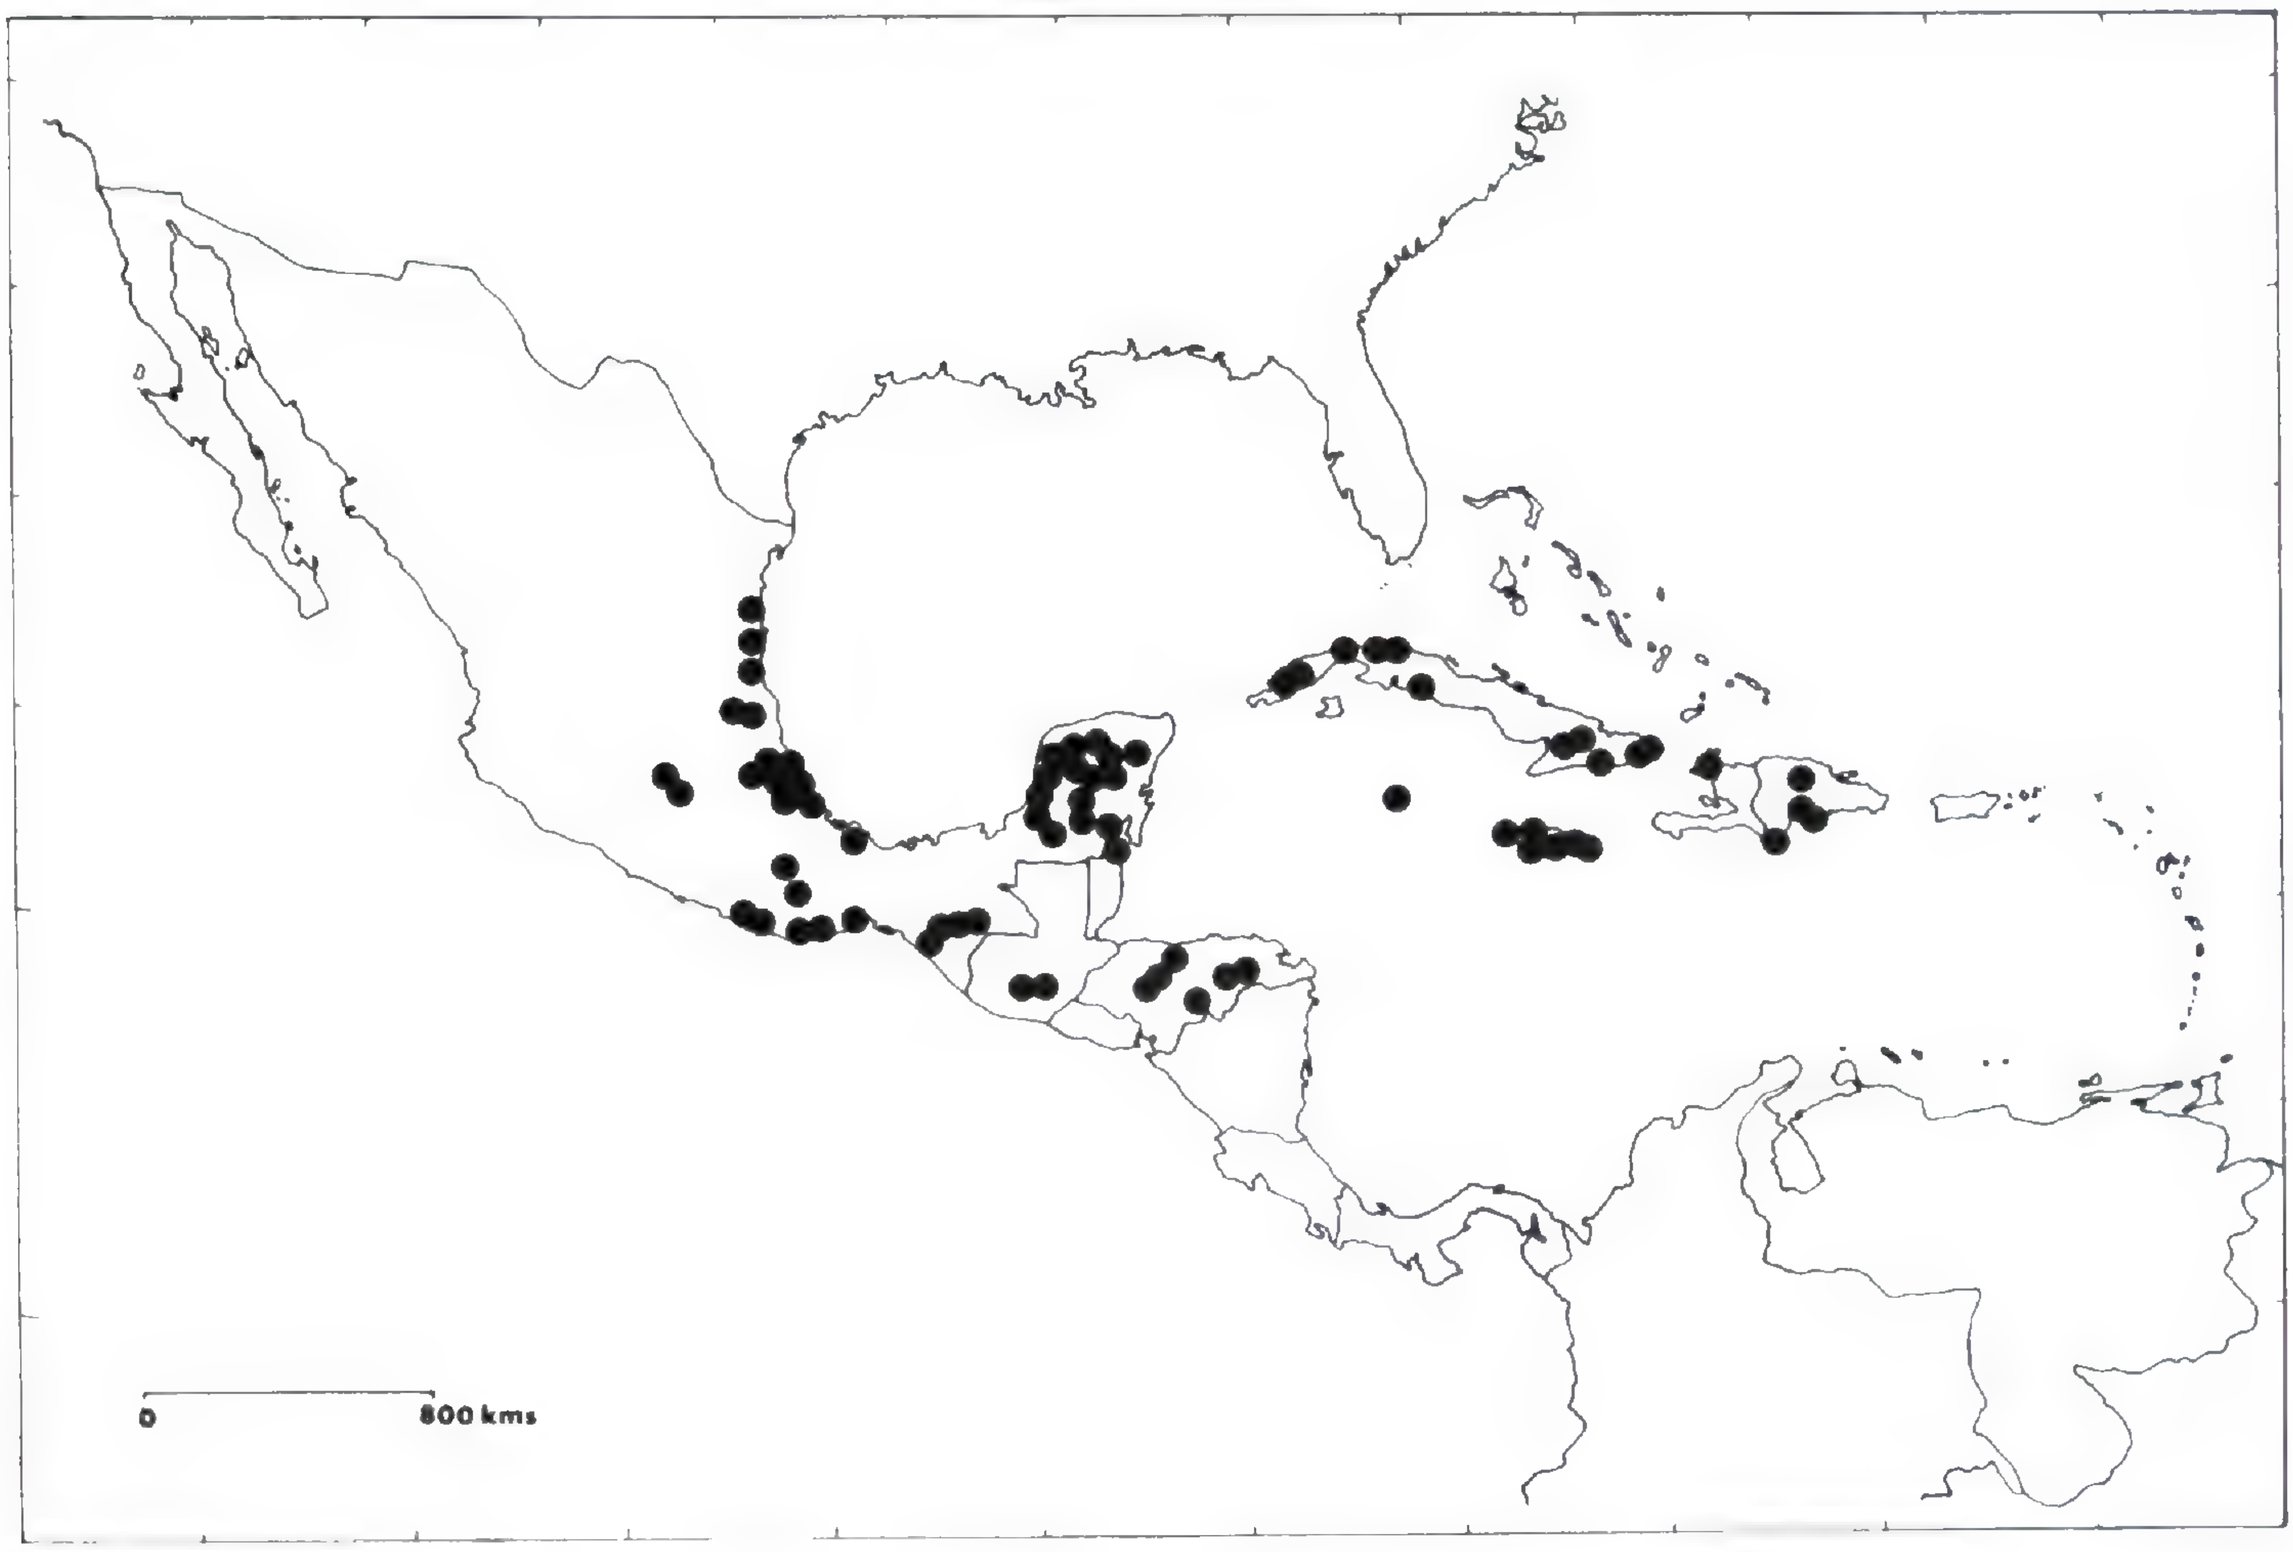

FIGURE 26. Distribution of *Ehretia tinifolia* L.

Calderitas, sobre el camino a Laguna Guerrero, *Cabrera & Cabrera 3223* (MO); a 5 km al W de La Pantera, sobre el camino a Margarita Maza, sobre la carretera via corta a Mérida, *Cabrera & Cabrera 3326* (MO); a 12 km al norte de San Felipe Bacalar, *Cabrera 4527* (MEXU—2 sheets); Laguna de Chichankanab, Mpio. José M. Morelos, 5 m, *Chan & Burhos 1361* (F); Cobá, *Lundell & Lundell 7696* (LL, MICH, US); *Téllez 1903* (BM, MEXU, MO, NY); Ruinas de Cobá, *Téllez 2349* (MEXU, MO); *Téllez & Cabrera 2365a* (BM, MO); Balneario Alvaro Obregón, a 25 km al sur de Ucum, *Téllez 2375* (MEXU, MO). Miller 1419* (US); Greenwood estate, 5 mi. ESE of Little River P.O., *Stearn 614* (A, BM—2 sheets). ST. THOMAS: Yallahs, 30 m, *Araque-Molina & Barkley 225438* (BM, IJ—3 sheets); Yallahs Valley–Green Valley, *Harris 6838* (F, NY—2 sheets); Grant's Pen, near sea level, *Proctor 28801* (BM, IJ). WESTMORELAND: 0.5 mi. SE of Mt. Airy school, 250 ft., *Proctor 36729* (IJ). PARISH UNKNOWN: Thicket Pepper, *Britton 1077* (NY); near camp, 67 m, *Campbell 5690* (F, NY, US); asylum grounds, *Fawcett s.n.* (BM); Malvern to Mountain side, *Harris 9755* (BM, F, NY, US); road from Hall-way Tree to Spanish Town Road, *Harris 10381* (A, BM, F, NY, US); without definite locality, *Macfadyen s.n* (K); *Molle s.n.* (GH); *Herb. Montinii* (S): *Swartz s.n.* (S); *Waters s.n.* (K); Trelawny, roadside near Duncans, *Whitefoord 1464* (BM, IJ). HAITI: Fond Parisien, *Bailey 175* (BH, US); Massif du Nord, Port-de-Paix, Bassin Bleu, 150 m, *Ekman H3992* (IJ, LL, NY, US); vicinity of Fond Parisien, Etang Saumatre, *Leonard 4173* (NY, US—2 sheets); vicinity of Port de Paix, ridge W of La Coup River, *Leonard & Leonard 11142* (US); vicinity of Bassin Bleu, 630–1,500 m, *Leonard 14709* (US—2 sheets). DOMINICAN REPUBLIC: Monte Cristi, Guayubín, 100 m or less, *Abbott 990* (GH, US); Santiago, Mao, 100–300 m, *Abbott 1069* (NY, US); Santiago, Navarrete, 100–300 m, *Abbott 1077* (US); in sylvestribus ad Río Gurabito, 200 m, *Eggers 1971a* (K); Santo Domingo, near Santiago, *Eggers 1990* (BM, G); Santo Domingo, Valle del Cibao, Prov. Santiago, Santiago, roadsides, near La Cienago, *Ekman H13235* (S, US); Barahona, Baum, *Fuertes 296* (BM, F, G, GH—2 sheets, LE, MO, NY, P, S, US); Santiago, along banks of the Río Yaque near Santiago, *Howard & Howard 9689* (A, B, BM, NY, US); Hotel Yaque, near Santiago City, *Jiménez 5688* (NY); Pedernales, near Las Mercedes from Cabo Rojo to Aceitillar, 400 m, *Liogier 16688* (NY); Santo Domingo, En Manigua, Pedernales, *Liogier 19691* (NY); a orilla de la carretera 100 entre Bani y Azua a nivel del mar, *Liogier 24871* (NY); Valverde, at stream crossing Autopista Duarte in center of town of Laguna Salada, 60 m, *Megía & Zanoni 6516* (NY); Azua, Santo Domingo, *Rose et al. 4005* (NY, US); Santo Domingo, Trujillo City, *Schiffino 150* (GH), *162* (GH).

EXCLUDED SPECIES

The majority of names published in *Ehretia* for the Neotropics are now considered synonyms of *Bourreria* and *Rochefortia*. In the following list, types have been examined when possible, but many of the names can be excluded from *Ehretia* based on the published descriptions. In placing the names I have relied heavily on the revisions of *Bourreria* (Miers, 1869; Schulz, 1911) and *Rochefortia* (Lefor, 1968) supplemented with notes from Johnston's extensive series of papers on the Boraginaceae. When *Ehretia* names are assigned to species of *Bourreria*, they should be considered cautiously as the best name available from the literature since *Bourreria* is probably the most nomenclaturally confused genus of Ehretioideae.

Ehretia acanthophora DC., Prodr. 9: 510. 1845. TYPE: Dominican Republic, Santo Domingo: *Bertero s.n.* (holotype, G-DC, not seen; microfiche, MO; isotypes, MO, P). = *Rochefortia acanthophora* (DC.) Griseb., Fl. British West Indies 482. 1864; O. Schulz in Urban, Symb. Antill. 7: 70. 1911; León & Alain, Fl. Cuba 4: 265. 1957; Lefor, 30. 1968.

Ehretia andrieuxii DC., Prodr. 9: 510. 1845. TYPE: Mexico. Puebla: May, *Andrieux 200* (holotype, G-DC, not seen; microfiche, MO). = *Bourreria andrieuxii* (DC.) Hemsley, Biol. Cent.-Amer., Bot. 2: 369. 1882; Miers, Contr. Bot. 2: 254. 1869; Gibson, Fieldiana Bot. 24, pt. 9: 113. 1970; Miller, Fl. Nicaragua (in press).

Ehretia bogotensis Spreng., Syst. Veg. 1: 648. 1825. = *Aegiphila bogotensis* (Sprengel) Moldenke, Repert. Spec. Nov. Regni Veg. Beih. 33: 114. 1933.

Ehretia bourreria Desf. (non L.), Ann. Mus. 1: 279. = *Bourreria recurva* Miers, Ann. & Mag. Nat. Hist. Ser. 4, 3: 203. 1869.

Ehretia bourreria L., Sp. Pl. 2 ed. 1: 275. 1762. = *Bourreria succulenta* Jacq., Enum. Syst. Pl. Carib. 14. 1760; O. Schulz in Urban, Symb. Antill. 7: 55, 56, and 62; León & Alain, Fl. Cuba 4: 269. 1957.

Ehretia calophylla A. Rich. in Sagra, Fl. Cuba 2: 112, t. 61. 1853. = *Bourreria rotata* (DC.) I. M. Johnston, J. Arnold Arbor. 30: 107. 1949; León & Alain, Fl. Cuba 4: 268. 1957.

Ehretia cassinifolia A. Rich. in A. Sagra, Fl. Cuba 2: 113. 1850. = *Bourreria cassinifolia* (A. Rich.) Griseb., Pl. Wright. Cub. 528; O. Schulz in Urban, Symb. Antill. 7: 67. 1911; León & Alain, Fl. Cuba 4: 270. 1957.

Ehretia cirrhosa Lam. = *Maripa scandens* Aublet; DC., Prodr. 9: 511. 1845.

Ehretia cumanensis DC., Prodr. 9: 511. 1845. = *Tournefortia hirsutissima* L., Sp. Pl. 140. 1753. O. Schulz (in Urban, Symb. Antill. 7: 50. 1911) treated this name as applicable to *Tournefortia*, not *Ehretia* or *Bourreria*. The name *Bourreria cumanensis* (Loefl.) O. Schulz is based on *Rhamnus cumanensis* Loefl., Iter Hispan. 182. 1758.

Ehretia cuneifolia Sessé & Mociño, Fl. Mexic. 51. 1894; ed. 2. 47. 1894. = *Bourreria spathulata* (Miers) Hemsley, Biol. Cent.-Amer., Bot. 2: 370. 1882; I. M. Johnston, J. Arnold Arbor. 30: 107. 1949.

Ehretia cymosa Willd. ex Roemer & Schultes (non Thonn). = *Tournefortia hirsutissima* L., Sp. Pl. 140. 1753; O. Schulz in Urban, Symb. Antill. 7: 50. 1911.

Ehretia divaricata A. Rich. (non DC.) in Sagra, Hist. Fis. Cuba, Bot. 11: 113. 1850. = *Bourreria succulenta* var. *revoluta* (Kunth in Humb., Bonpl. & Kunth) O. Schulz in Urban, Symb. Antill. 7: 59. 1911.

Ehretia divaricata DC., Cat. Hort. Monspel. 108. 1813; Prodr. 9: 506. 1845. = *Bourreria divaricata* (DC.) G. Don, Gen. Hist. 4: 389. 1838; O. Schulz in Urban, Symb. Antill. 7: 69. 1911; León & Alain, Fl. Cuba 4: 271. 1957.

Ehretia domingensis DC., Prodr. 9: 508. 1845. = *Bourreria domingensis* (DC.) Griseb., Fl. Brit. W.I. 482. 1861; Miers, Ann. & Mag. Nat. Hist. Ser. 4, 3: 202. 1869; O. Schulz in Urban, Symb. Antill. 7: 64. 1911.

NEW AND CRITICAL TAXA OF EUPHORBIACEAE FROM SOUTH AMERICA[1]

Michael J. Huft[2]

ABSTRACT

Study of neotropical Euphorbiaceae for various floristic and taxonomic projects has uncovered several novelties. New taxa proposed in this paper are *Dalechampia liesneri* from southern Venezuela, *Richeria tomentosa* from Colombia, *Tragia rubiginosa* from Peru, and the genus *Tacarcuna*, including the three new species *T. gentryi*, from the border of Panama and Colombia, *T. amanoifolia* from Peru, and *T. tachirensis* from Venezuela. In addition it is shown that *Caryodendron janeirense* Muell. Arg. is the correct name for the plant hitherto known as *C. grandifolium* (Muell. Arg.) Pax.

The Euphorbiaceae, one of the largest families in the Neotropics, remains one of the least well understood. The largest genera, *Acalypha*, *Croton*, *Euphorbia*, and *Phyllanthus*, have not been critically revised in this century, and only a handful of other, smaller genera have been the subject of modern study. Even at the most basic descriptive level, a great deal of work remains to be done, and the mere discovery of a new species can often lead to much insight into the taxonomy of its congeners. Such is the case with the collection of taxa proposed here, which result from study preparatory to the *Flora of the Venezuelan Guayana* (J. Steyermark & collaborators, in prep.), *Checklist of the Flora of Chocó Province, Colombia* (A. Gentry & E. Forero, in prep.), or from serendipitous discovery in the herbarium.

Caryodendron janeirense Muell. Arg. in C. Mart., Fl. Bras. 11(2): 707. 1874. *Centrodiscus grandifolius* Muell. Arg. in C. Mart., Fl. Bras. 11(2): 327. 1874, nom. inval. *Caryodendron grandifolium* (Muell. Arg.) Pax in Engler & Prantl, Nat. Pflanzenfam. III. 5: 52. 1890, nom. illeg. TYPE: Brazil. Rio de Janeiro: *Riedel 1051* (presumably G).

Mueller published the name *Centrodiscus grandifolius* with description and citation of type. Before this went to press however, he added as a separate item on a different page "Addenda and Corrigenda" in which he pointed out that his *Centrodiscus grandifolius* belongs to Karsten's genus *Caryodendron* and that it differs from the only species, *Caryodendron orinocense* Karsten, by, among other things, having smaller leaves. Apparently thinking that the epithet *grandifolium* would be inappropriate in *Caryodendron*, he assigned the new plant the name *Caryodendron janeirense*, which is the correct name for the species. *Centrodiscus grandifolius* was not published before *Caryodendron janeirense*, pp. 273–754 of Volume 11, Part 2, appearing together on May 1, 1874 (Stafleu & Cowan, 1981: 333–337). Mueller was merely making a last-minute correction to text already too far along in press to be changed internally. It is therefore clear that the name *Centrodiscus grandifolius* Muell. Arg. was not accepted by its author when published and therefore is invalid according to Article 34.1 of the *International Code of Botanical Nomenclature* (Greuter, 1988). The combination of Pax based on that name is nomenclaturally superfluous. For the same reason, the generic name *Caryodendron* Muell. Arg., published simultaneously with *Caryodendron grandifolius* Muell. Arg. and likewise not accepted by its author when published, is also invalid.

[1] I am indebted to Dr. W. Scott Armbruster of the University of Alaska for valuable discussions concerning *Dalechampia liesneri*, and to the curators of the herbaria cited for making their specimens available. The excellent drawings were made by Mrs. Carol G. Schneider (Figs. 1 and 3) and Mrs. Wan-Ling Peng (Fig. 2).

[2] Missouri Botanical Garden. Mailing address: Department of Botany, Field Museum of Natural History, Roosevelt Road at Lake Shore Drive, Chicago, Illinois 60605, U.S.A.

Dalechampia liesneri Huft, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Depto. Atures, stream 0.5–2 km E of Río Coro-Coro, W of Serranía de Yutaje, 05°38′N, 66°07′30″W, 200 m, 19 Feb. 1987, *R. L. Liesner & B. Holst 21244* (holotype, MO; isotypes, U, VEN not seen). Figure 1.

Frutex (vel herba) volubilis; caules et folia glabra vel sparsim brevipuberula. Folia simplicia, longipetiolata; laminae ovato-deltatae, basi 5-nerves, apice acutae; basi late cordatae. Inflorescentiae dissitae, longipedunculatae, floribus compactis. Flores masculi ad 8; sepala ovata, acuta, sub anthesi reflexa; stamina 8–10, filamentis connatis, tubum longum gracilem formantibus. Flores feminei 3, subsessilis, pedicello ad fructus maturitatem multo elongato; sepala 6, lineari-lanceolata; stylus gracilis, elongatus. Capsulae glabrae vel brevipuberulae, laeves. Semina ovoidea vel subglobosa, laevia, brunnea.

Twining vine; stems terete or slightly angulate, glabrous or very sparsely short-puberulent. *Leaves* simple, on petioles to 10 cm long, these pinched at apex and at base and puberulent; blades ovate-deltate, membranous, glabrous or the principal veins minutely puberulent, 5-nerved, the secondaries few near apex of blade, ascending, the tertiaries reticulate, conspicuous, the apex acuminate, the base openly cordate, stipellate, the margin minutely and remotely denticulate. *Inflorescences* bisexual, widely spaced, compact, the peduncle slender, densely puberulent, 1–4 cm long. *Staminate flowers* distal, up to 8 present, the pedicels 2–5 mm long; bracts lanceolate, brown puberulent, acute, 2–4 mm long; buds fusiform, acute; sepals 5, ca. 2 mm long, membranous, ovate, acute, sparsely hirtellous, reflexed at anthesis; stamens 8–10, the filaments united nearly their entire length to form a slender tube 4–5 mm long, the anthers free at apex, the tube penicillate toward apex. *Pistillate flowers* 3, 1 or 2 sometimes aborting before maturity, proximal, subsessile at anthesis, the pedicel densely puberulous-hirtellous, greatly elongating in fruit (to 5 cm); sepals 6, linear-lanceolate, 2.8–3.2 mm long, acute, sparsely short-puberulent, the base thickened, the young fruit densely short-pilose; style slender, elongate, to 15 mm long, 0.2–0.3 mm thick, densely puberulent toward the base, otherwise glabrous. *Capsule* smooth, 3-lobed, short-puberulent, not seen entire, apparently 6–7 mm diam.; seeds ovoid to subglobose, smooth, ca. 4 mm diam., brown.

The pantropical genus *Dalechampia* contains over 100 principally neotropical species. Numerous recent discoveries (Armbruster, 1984, 1988, 1989; Huft, 1984; Webster, 1967, 1988; Webster & Armbruster, 1979, 1982), many of them of taxonomic and phylogenetic importance, attest to the need for the critical study this genus is now receiving at the hands of Dr. Grady L. Webster and Dr. W. Scott Armbruster.

Dalechampia liesneri belongs to sect. *Rhopalostylis* Pax & K. Hoffm., the most primitive section of the genus, which apparently is restricted to the northern and western Amazonian basin. Only four species have previously been described from this group: *D. micrantha* Poeppig from western Brazil and eastern Peru, *D. parvibracteata* Lanj. from the Guianas, *D. olympiana* Kuhlm. & Rodrigues from northern Brazil, and the recently described *D. attenuistylus* Armbruster from southern Venezuela (Armbruster, 1989). The genus *Megalostylis* S. Moore, whose only species, *M. poeppigii* S. Moore, appears to be based on an isotype of *D. micrantha*, is synonymous with sect. *Rhopalostylis*.

Section *Rhopalostylis* is characterized by absence of the showy white, pinkish, purplish, or green bracts that are so characteristic of the rest of the genus; absence of resiniferous glands in the inflorescences; and larger, usually basally swollen, styles. *Dalechampia liesneri* is distinctive in its few-flowered, long-pedunculate, inflorescences and long, thin styles that are not at all swollen toward the base. Dr. Armbruster (pers. comm.), who is preparing a revision of this group, has discovered an additional population of this species near San Pedro de Cataniapo (ca. 60 km ESE of Puerto Ayacucho) in southern Venezuela, and he reports that it is probably not uncommon in that region.

It is a pleasure to name this species after Ronald Liesner of the Missouri Botanical Garden who has collected extensively in Venezuela during the past decade and has been responsible for many discoveries and additions to our knowledge of the flora of that country.

Richeria tomentosa Huft, sp. nov. TYPE: Colombia. Chocó: Municipio de Quibdó, bosque frente al barrio Obrero, 24 May 1985, *Espina & García 1518* (holotype, MO).

Arbor ad 25 m alta, dioecia; cortex crassus exaratus. Folia alterna brevipetiolata; laminae late obovato-ellipticae, infra dense brunneo-tomentosae vel glabratae, supra moderate pilosae vel glabratae, apice rotundatae, obtusae, vel breviacuminatae, basi rotundatae vel late cuneatae, margine crenato-undulatae. Inflorescentiae numerosae laterales sub foliis, ex paniculis fasciculatis 2–4 cm longis constans. Flores masculi in glomerulis sessilibus vel subsessilibus. Flores feminei non visi, sessiles vel brevipedicellati; fructus juvenes dense brunneo-tomentosi pyriformes, stylis 3 valde recurvis. Capsulae ellipsoideo-oboideae obscuro trigonae glabrae; columella non persistens alis latis papyraceis.

Tree to 25 m high, dioecious; twigs with thick bark formed into flattened ridges and narrow furrows, densely hirsutulous to glabrate toward apex. *Leaves* alternate, short-petiolate; stipules obsolete; petioles 0.5–2.5 cm long, stout, densely hirsutulous to glabrate; blades chartaceous to subcoriaceous, broadly obovate-elliptic, 10–23 cm long, 7–12 cm wide, 1.5–2.8 times as long as wide, densely brown tomentose to glabrate below, moderately pilose to glabrate above, the apex rounded, obtuse, or short-acuminate, the base rounded, obtuse, or broadly cuneate, the margins entire to obscurely crenate-undulate; midrib prominent below, the secondary nerves 14–26 on a side, parallel, arching somewhat toward the margin of the blade, prominent below, light-colored above, neither raised nor impressed, the tertiary veins connecting the secondaries at right angles, regularly spaced, prominulous below. *Inflorescences* numerous, lateral, below current leaves, consisting of clustered panicles 2–4 cm long, the axes densely brown tomentose when young, becoming densely puberulent at maturity. *Staminate flowers* 1–3 in sessile or subsessile glomerules, the buds globose, 0.7–1.1 mm diam. *Pistillate flowers* not seen, sessile or short-pedicellate; calyx persistent on young fruits, tomentose outside, the lobes 1–1.5 mm long, deltate, ca. ⅔ the length of the calyx; young fruits densely brown tomentose, pyriform, the styles 3, ca. 1 mm long, strongly recurved, united at base, glabrous or with a few scattered hairs. *Capsules* ellipsoid-obovoid, obscurely trigonous, glabrous, smooth, 11–16 mm long, 6–9 mm diam., the styles persistent, minute, the columella with broad papery wings, not persistent.

This very distinctive species is easily distinguished from the four to six other species of *Richeria* by the densely tomentose lower leaf surfaces on many specimens and by the short, compact, highly branched inflorescences. The prominent midrib and secondary veins are also distinctive. The widespread *R. racemosa* (Poeppig) Pax & K. Hoffm. has staminate spikes longer than the leaves rather than the short, compact, clustered panicles that are characteristic of *R. tomentosa*, and the cymules are distinctly pedunculate and two- or three-flowered. Two other South American species, *R. grandis* Vahl and *R. obovata* (Muell. Arg.) Pax & K. Hoffm., have longer and less compact inflorescences than *R. tomentosa* and are completely glabrous; their leaf margins are prominently crenate-undulate (vs. entire or obscurely crenate-undulate). The recently described *R. dressleri* Webster (Ann. Missouri Bot. Gard. 75: 1094. 1988), from Panama and apparently Costa Rica, is distinctive in its two-carpellate ovaries and fruits.

Additional specimens examined. COLOMBIA. VALLE: Bajo Calima Concessión, ca. 20 km N of Buenaventura, behind Pulpapel Forest Station, 3°40′N, 77°0′W, 50 m, 26 May 1987, *Faber-Lagoenden et al. 675* (F); Bajo Calima, ca. 15 km N of Buenaventura, Cartón de Colombia Concessión, 3°56′N, 77°08′W, ca. 50 m, 14 Feb. 1983, *Gentry et al. 40219* (F); 18 Feb. 1983, *Gentry & Juncosa 40483* (F); 27 Mar. 1986, *Gentry et al. 53648* (F); Bajo Calima, Dindo area, pluvial forest, 3°59′N, 76°58′W, ca. 100 m, 20 July 1984, *Gentry & Monsalve 48390* (MO); Bajo Calima, Cartón de Colombia Concessión, Dindo 4 area, 11 km E of Buenaventura–Río Calima road, 3°55′N, 77°0′W, 50–100 m, 14 Dec. 1985, *Gentry et al. 53295* (F, MO); 27 Feb. 1985, *Monsalve 716* (F, MO); Bajo Calima, Juanchaco Palmeras area, 3°55′N, 77°02′W, 50 m, 29 Aug. 1986, *Gentry & Cuadros 55602* (F); Bajo Calima, Concessión Pulpapel Buenaventura, 3°55′N, 77°W, ca. 100 m, *Monsalve 876* (F).

Tacarcuna Huft, gen. nov. TYPE: *Tacarcuna gentryi* Huft.

Arbor, ut videtur dioecia; foliis alternatis, simplicibus, petiolatis, stipulatis; inflorescentiis axillaribus, glomeratis; sepalis 3 vel 5, imbricatis; petalis 3 vel 5; staminibus 5, liberis; pistillodio effecto; ovariis 3, uniovulatis; stylis 3; fructibus capsularibus.

Trees, apparently dioecious. *Leaves* alternate, simple petiolate; stipules small, deciduous. *Inflorescences* axillary, sessile or short-petiolate, glomerate. *Staminate flowers* (seen only in *T. gentryi*) short-pedicellate; calyx lobes 5, imbricate, petals 5, equaling or exceeding the sepals; stamens 5, free; pistillode well developed. *Pistillate flowers* pedicellate, the pedicel elongating in fruit; perianth as in the pistillate flowers (sepals and petals only 3 in *T. tachirensis*, in which staminate flowers are unknown), persistent on the mature fruit; carpel 3-locular, the locules uniovulate; styles 3, divided at apex. *Fruits* capsular, the thin outer wall separating from the thicker inner wall at dehiscence; seeds apparently ovoid-lenticular, smooth or perhaps sculptured, often misshapen, rarely seen mature.

This genus of small to medium-sized trees seems

quite unlike any other Euphorbiaceae in the Neotropics, and I have been unable to match it with any Old World representatives of the family. The collections available have mature capsules and young fruits that retain the pistillate calyx and corolla. Only one specimen (*T. gentryi*, *Gentry et al. 16901* MO), however, has staminate flowers, and these are partially embedded in mounting glue. Additional material of *T. gentryi* containing abundant staminate flowers was collected but has apparently been lost or misplaced (A. Gentry, pers. comm.). Since characters of the staminate flowers are of great importance in generic delimitation in the Euphorbiaceae, I have been reluctant for some time to describe this new genus, pending recovery or re-collection of staminate material. However, partial dissection of the available staminate flowers revealed five free stamens and a well-developed staminode; these features along with the glomerate, axillary inflorescences, presence of petals, and imbricate calyx mark this as a previously undescribed genus.

Only recently have collections of two additional species of this remarkable genus come to light, and, even though staminate material is lacking in these species, all three species are described together in the hopes of stimulating further exploration. In addition to the characters already mentioned, the three species of *Tacarcuna* are held together by the combination of ovate-lanceolate or obovate-lanceolate leaves with very short, stout petioles; the sepals and often the petals more or less densely puberulous centrally on the outer surface, and with distinctly hyaline margins; deeply lobed capsules somewhat depressed at the apex; and a network of low ridges on the mature capsules, especially prominent in *T. gentryi*, less so in *T. amanoifolia*, and largely obscured by the velutinous indument in *T. tachirensis*.

KEY TO THE SPECIES OF *TACARCUNA*

1a. Branchlets and petioles brown strigillose; secondary veins 5–7, broadly arching; sepals and petals 5 ..... *T. gentryi*
1b. Branchlets and petioles glabrous; secondary veins more than 12, arching only at margins; sepals and petals 3.
  2a. Capsules glabrous to sparsely puberulent; sepals navicular; leaves strongly cuspidate-acuminate ..... *T. amanoifolia*
  2b. Capsules velutinous; sepals more or less plane; leaves acute or rarely short-acuminate ..... *T. tachirensis*

Tacarcuna gentryi Huft, sp. nov. TYPE: Panama. Darién: lower montane wet forest, S slope of westernmost summit of Cerro Tacarcuna Massif between Pucuro base camp and Tacarcuna summit camp, 1,400–1,600 m, 21 July 1976, *Gentry, Leon & Forero 16869* (holotype, MO; isotypes, COL not seen, DAV not seen, F). Figure 2.

Arbor mediocra, dioecia; ramulis junioribus dense puberulis; foliis lanceolate ovatis vel ellipticis, glabris; nervis secondariis 7–9; sepalis et petalis similibus, extus dense brunneo-puberulis, ad marginem late hyalinis; capsulis fasciculatis, pedicellatis, 8–10 mm altis, 10–12 mm latis, parece brunneo-pubescentibus, leviter porcatis.

Tree 6–10 m high, dioecious; branchlets slender, densely puberulent. *Leaves* alternate; blades lanceovate to elliptic, entire, (8–)10–16 cm long, 3–5.5 cm wide, glabrous or brown strigillose below toward the base; apex acuminate; base obtuse; midvein prominent; lateral veins 7–9 per side, prominent, arching; veinlets forming a prominent reticulum; petioles short, thickened, 3–5 mm long, glabrous or brown-strigillose; stipules deciduous, deltate, 1.6–2.2 mm long, 0.8–1 mm wide, shallowly cucullate, brown strigillose. *Inflorescences* axillary, glomerate. *Staminate flowers* apparently several in each axil; pedicel ca. 2 mm long, finely and densely puberulous with short brown hairs; sepals 5, valvate, 1.2–1.5 mm long, oblong, rounded at apex, densely brown puberulent outside except the broad hyaline margin, glabrous inside; petals similar; stamens 5, free; disk present, the features not clearly seen; pistillode well developed. *Pistillate flowers* 2–5 in each axil (seen only in fruit); fruiting pedicel 8–14 mm long, stout, finely and densely puberulous with short brown hairs; perianth as in staminate flowers, persistent in fruit; styles 3, strongly recurved, densely brown puberulent on the outer surface, glabrous on the inner surface, bifid at apex for ca. ¼–⅓ their length; style branches divergent and recurved. Immature *capsules* brown tomentose; mature capsules prominently 3-lobed, drying black, 8–10 mm high, 10–12 mm diam., pubescent with scattered short brown hairs, covered with a network of low ridges, the columella unknown; seeds (immature, misshapen) apparently reniform, ca. 8 mm long.

Tacarcuna gentryi is known only from montane rainforest and elfin forest on the Cerro Tacarcuna massif on the border of Panama and Colombia. It is distinctive in its brown strigillose stems and petioles, membranous leaf blades with widely spaced and broadly arching secondary nerves, and five-merous perianth.

I am pleased to name this species after Dr. Alwyn H. Gentry, who in the course of two long

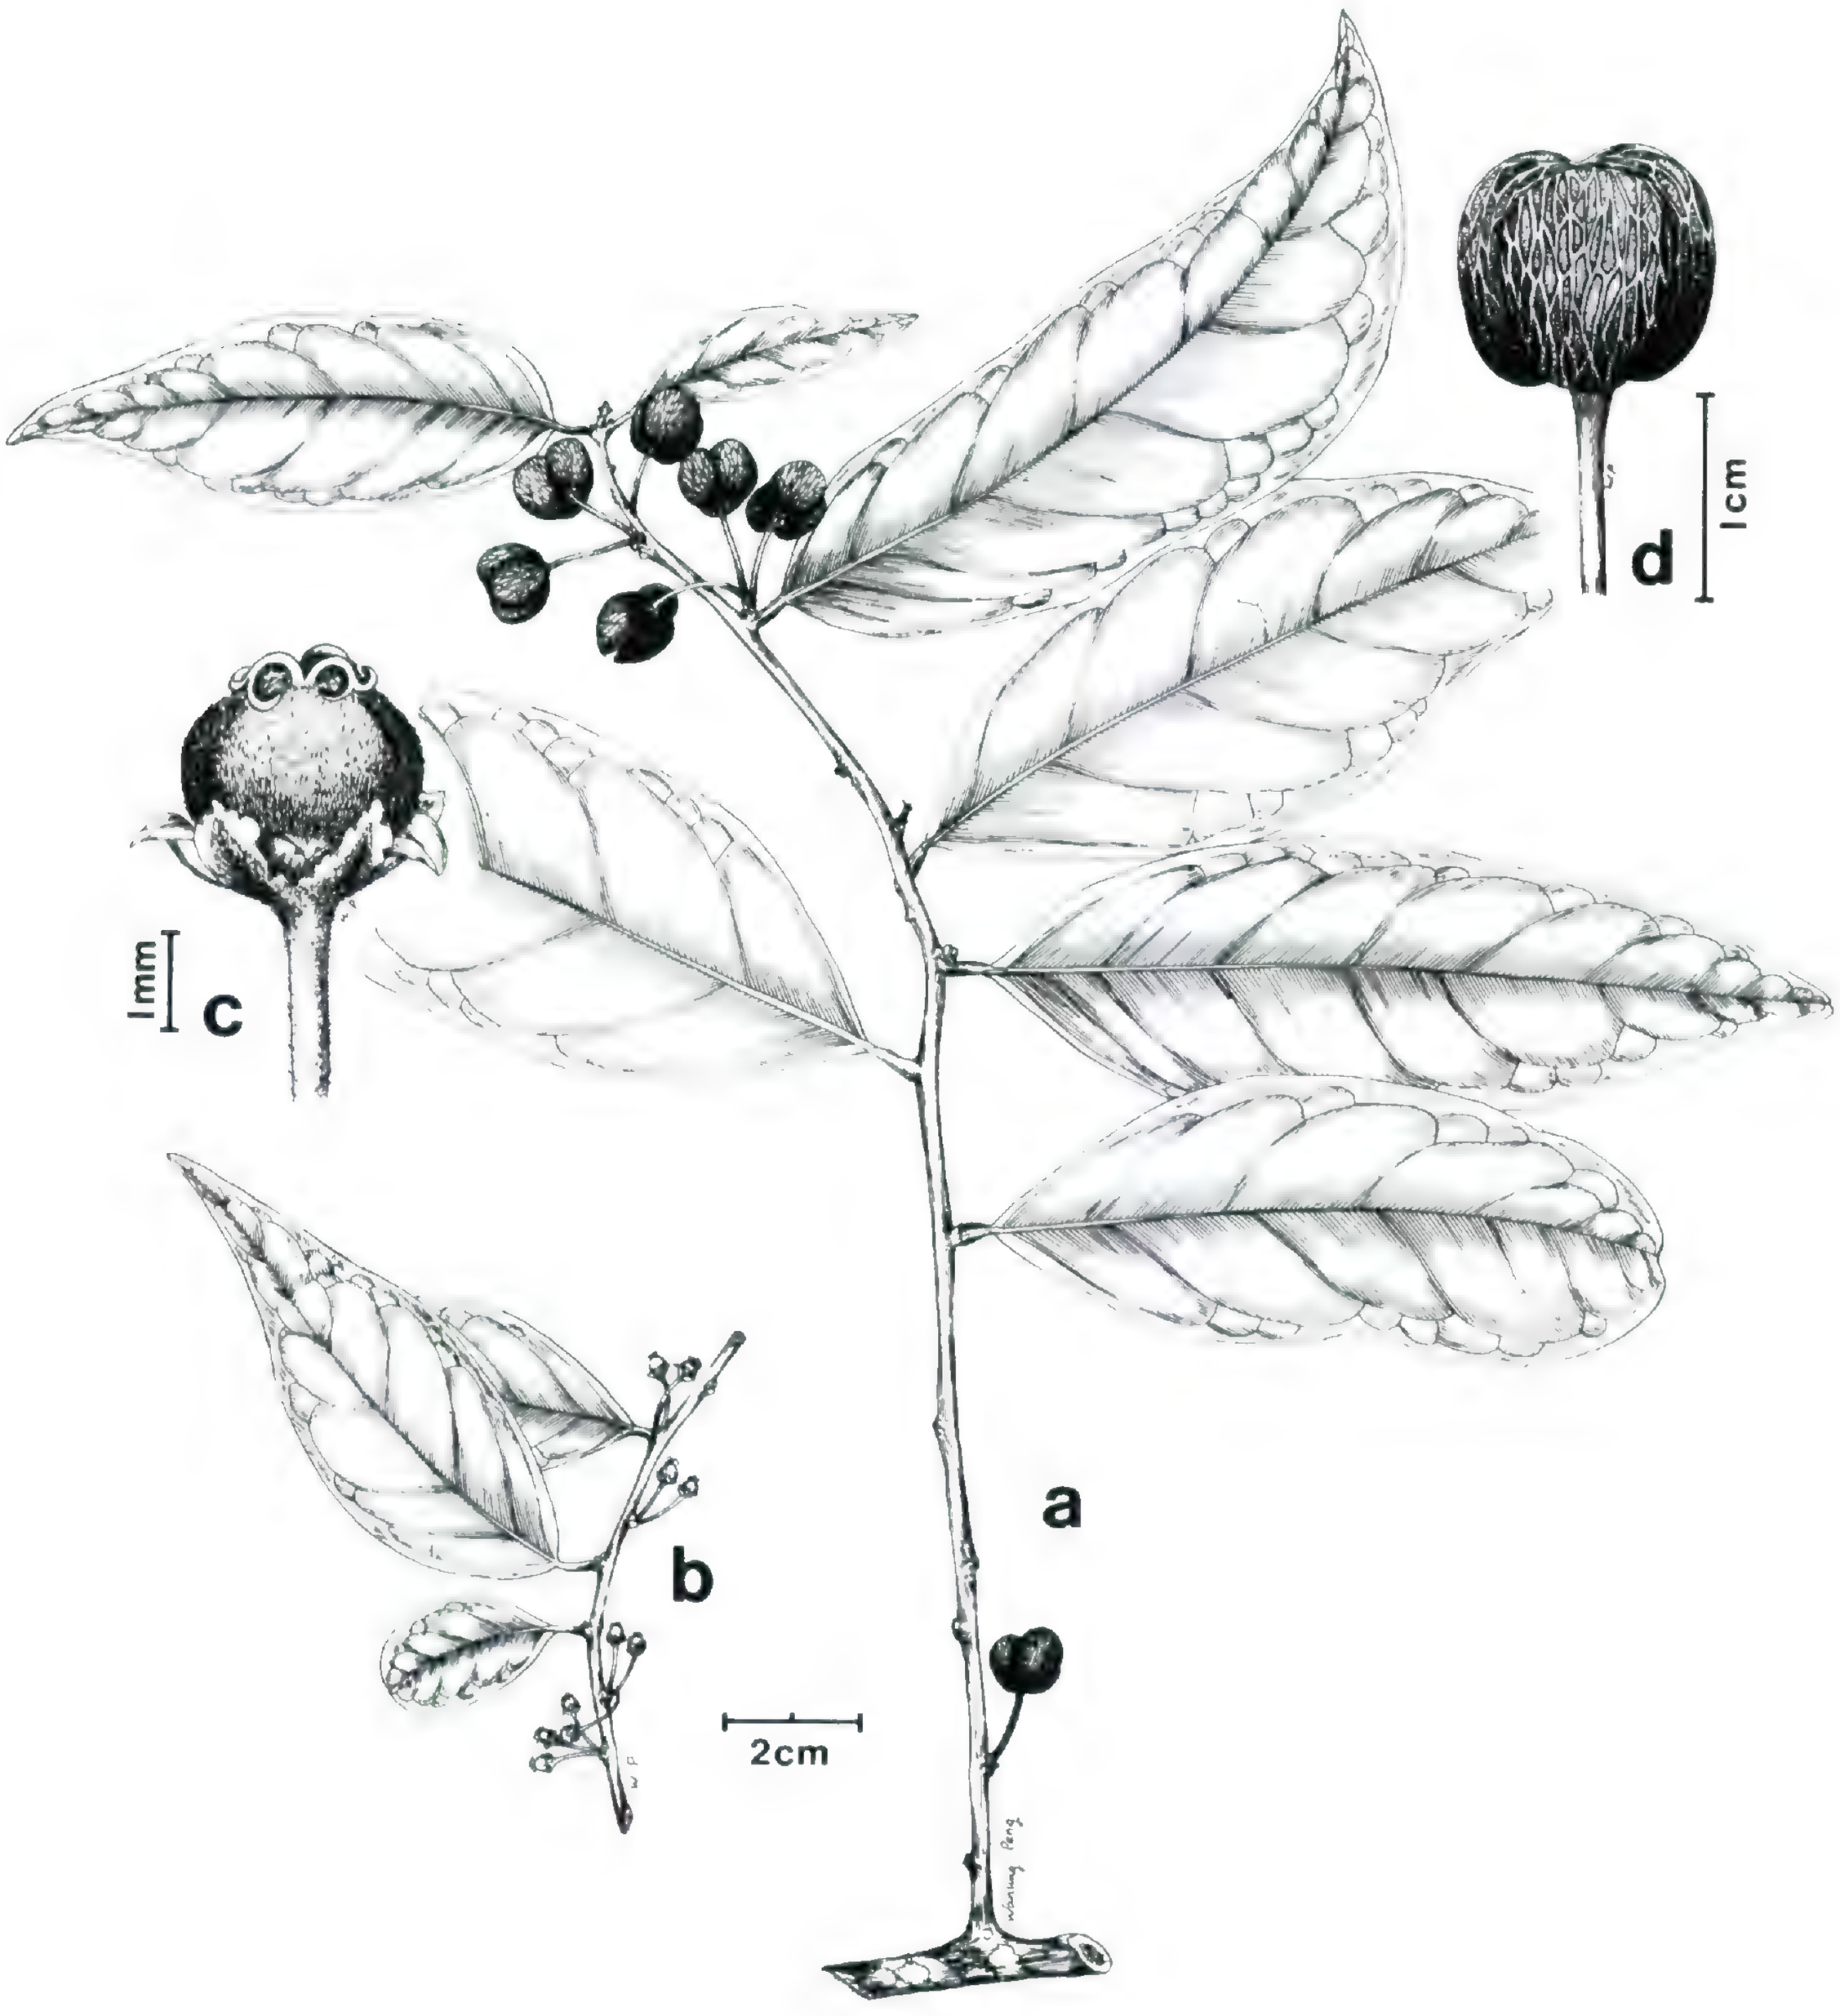

FIGURE 2. *Tacarcuna gentryi.*—a. Leafy branch with mature capsules.—b. Branch with immature capsules. (Same scale for a and b.)—c. Immature capsule.—d. Mature capsule. (Based on *Gentry et al. 16869.*)

expeditions in the mid 1970s was the first botanist to collect the rich and biologically significant flora on the Cerro Tacarcuna Massif on the boundary between Central and South America (Gentry, 1977).

Additional specimens examined. PANAMA. DARIÉN: Cerro Tacarcuna, W ridge, trail toward Río Pucuru just below summit camp, 1,500-1,600 m, *Gentry & Mori 14121* (MO), *14143* (MO); elfin forest near top of westernmost peak of Cerro Tacarcuna Massif, 1,720 m, *Gentry et al. 16901* (F, MO).

Tacarcuna amanoifolia Huft, sp. nov. TYPE: Peru. Maynas: Dtto. Iquitos, Río Momon, 3 km above jct. with Río Nanay, ca. 105 m, 10 Jan. 1976, *S. McDaniel & M. Rimachi Y. 20414* (holotype, MO-3622561).

Arbor mediocra, ut videtur dioecia; ramulis junioribus glabris; foliis lanceolate obovatis, glabris; nervis secondariis 12–16, sepalis 3, navicularibus, extus plus minusve puberulis, ad marginem late hyalinis, petalis 3, glabris, ad apicem cucullatis; capsulis fasciculatis, pedicellatis, 5–6 mm altis, 9 10 mm latis, parece pubescentibus, leviter porcatis.

Tree 7–13 m high, apparently dioecious; branchlets slender, glabrous. *Leaves* alternate,

short-petiolate; blades elliptic to oblanceolate-obovate, entire, (5–)8–12 cm long, (1.8–)3–5 cm wide, 1.9–2.8 times as long as wide, glabrous, somewhat leathery; apex cuspidate-acuminate; base acute to acuminate; midvein prominent on both sides; lateral veins 12–16 per side, arching near the margin of the blade, connected by a fine reticulum; petioles stout, 3–6 cm long, glabrous; stipules fugacious, not seen, leaving a horizontal scar 2–2.5 mm long. *Inflorescences* axillary, glomerate. *Staminate flowers* not seen. *Pistillate flowers* 6–8 in each axil, seen only in fruit; fruiting pedicels 3–4 mm long in immature fruits, 6–9 mm long in mature fruits, ± densely puberulous; sepals 3, imbricate, strongly navicular, ca. 1.8 mm long, ± densely puberulous except on the broad hyaline margins, glabrous inside; petals 3, exceeding the sepals, glabrous, cucullate at apex, the margins hyaline; styles 3, strongly recurved, ca. 2 mm long, ± densely puberulous on the outer surface, especially toward the base, glabrous on the inner surface, bifid ca. ½–⅔ their length; style branches divergent and recurved. Immature *capsules* tomentose, conspicuously 3-lobed; mature capsules deeply 3-lobed, not drying black, 5–6 mm high, 9–10 mm diam., sparsely beset with minute scattered hairs, covered with an inconspicuous network of low ridges, the columella persistent, 3–3.5 mm long, with 3 narrow conspicuous wings running the length of the axis; seeds (misshapen) apparently 5–6 mm long.

This is the only species of *Tacarcuna* known from lowland areas; the two collections were made in occasionally inundated mature forest at ca. 0–100 m elevation. The leaf blades of *T. amanoifolia* are thicker and more lustrous than in *T. gentryi*, and are marked by their more or less broadly obovate-lanceolate outline with a conspicuous cuspidate-acuminate tip. These features along with a sometimes lighter color along the margins impart to the leaves an appearance strikingly similar to that of *Amanoa guianensis* Aublet, a widespread euphorbiaceous tree of the lowland forests of northern South America and southern Central America. Its short mature pedicels give the fruiting branch a more congested appearance than in *T. gentryi*.

Additional specimen examined. PERU. MAYNAS: Dtto. Iquitos, Río Nanay, two bends below entrance to Mapa Cocha, 14 Jan. 1976, *McDaniel & Rimachi 20465* (MO).

Tacarcuna tachirensis Huft, sp. nov. TYPE: Venezuela. Táchira: Cerro Las Minas, 18 km SE of Santa Ana, along steep slopes leading to Cerro Azul of Cerro Las Minas, 7°36′N, 72°13′W, 1,200–1,380 m, 6 May 1981, *R. Liesner & M. Guariglai 11874* (holotype, MO; isotypes, DAV not seen, F, VEN not seen, and to be distributed).

Arbor parva, ut videtur dioecia; ramulis junioribus glabris; foliis lanceolate ovatis vel lanceolate obovatis, glabris; nervis secondariis 17–25; sepalis 3, extus leviter puberulis vel glabratis, ad marginem hyalinis, petalis 3, similibus; capsulis fasciculatis, pedicellatis, ut videtur 6–8 mm altis, 12–13 mm latis, velutinis, leviter porcatis.

Tree to 3 m high, apparently dioecious; branchlets glabrous. *Leaves* alternate, short-petiolate; blades elliptic, lanceolate-ovate or lanceolate-obovate, entire, 7–12 cm long, 3–5 cm wide, 2–2.8 times as long as wide, glabrous, chartaceous; apex acute or scarcely short-acuminate; base obtuse to rounded; midvein prominent on both sides; lateral veins 17–25 per side, arching near the margin of the blade, scarcely prominulous, ± inconspicuous, connected by a fine reticulum; petioles 2–5 mm long, thickened, glabrous; stipules fugacious, ligulate, ca. 7 mm long, ca. 2.5 mm wide, rounded at apex, leaving a conspicuous horizontal scar. *Inflorescences* axillary, glomerate. *Staminate flowers* not seen. *Pistillate flowers* usually 4 in each axil, seen only in post-mature fruit; fruiting pedicels 1–1.5 cm long, ± puberulous; sepals 3, persistent on mature capsules, imbricate, ovate, ca. 2.5 mm long, glabrous to sparsely puberulous except the hyaline margins, glabrous inside; petals 3, similar to sepals; styles not evident (no intact capsules seen). *Mature capsules* apparently 6–8 mm high, 12–13 mm diam., shallowly 3-lobed, densely velutinous, the network of low ridges barely discernible; columella persistent, ca. 5 mm long, thickened at base, with 3 narrow, scarcely discernible wings running the length of the axis, these rarely larger and membranous; seeds smooth, brown, wrinkled, semiglobose with a vaguely triangular cross section, ca. 6 mm diam.

This species is known only from a single collection on steep forested slopes above 1,200 m. Only post-mature (i.e., already dehisced) capsules are available. The capsules are distinctive in their densely velutinous indument. The leaves are similar to those of *T. amanoifolia* in their thicker texture and lustrous surface, but are more characteristically lanceolate-ovate rather than lanceolate-obovate, and have more closely spaced and more numerous secondary veins; the tips are acute (rarely short-acuminate) rather than prominently cuspidate-acuminate as in *T. amanoifolia*.

Tragia rubiginosa Huft, sp. nov. TYPE: Peru. Loreto: Mishuyacu, near Iquítos, 100 m, Apr. 1930, *G. Klug 1176* (holotype, US-1456205). Figure 3.

Frutex volubilis, monoeicus; caules pilosi. Folia alternata brevipetiolata; stipulae anguste lanceolatae basi hastatae; laminae lanceolatae vel oblanceolatae, supra glabrae vel ad costam sparsim pubescentes, infra minime pilosae, apice acuminatae, basi cordato-hastatae, margine integrae vel remote denticulatae, basi 3-nerves. Inflorescentiae axillares, spicatae, ut videtur unisexuales, longipeduculatae, plus minusve reflexae. Flores masculi brevipedicellati; lobi calycis 5, 1.5–1.8 mm longi, elliptici, valvati, ad anthesin reflexi; stamina 5; antherae subsessiles, glandulae discorum 5, intrastaminales. Flores feminei lobis calycis 5, ovato-ellipticis, ca. 1.5 mm longis, acutis; stigmata subsessilia, 3, crassa. Capsulae ut videtur 3-lobatae, cristis humilibus reticulatibus, leviter puberulentes; semina globosa, laevia, 4–4.5 mm diametro, ecarunculata.

Vine, monoecious; stem pilose. *Leaves* alternate, on petioles 5–10 mm long, these densely hirsutulous; stipules narrowly lanceolate, appressed, 3.5–5 mm long, sparsely pilose, the base broadly and conspicuously hastate, the lobes rounded; blades lanceolate to oblanceolate, 7.5–11 cm long, 2.7–3.5 cm wide, 2.8–3.7 times as long as wide, glabrous above or sparsely pubescent on midrib, very sparsely pilose below, acuminate at the apex, narrowed to a cordate-hastate base with rounded lobes ca. 1 mm long, the margin entire to remotely denticulate, 3-nerved from base, the central nerve giving rise to another 5–7 pairs of secondaries. *Inflorescences* axillary, spicate, apparently unisexual, ± reflexed, the peduncle densely brown-puberulent, ca. 3 cm long. *Staminate flowers* on pedicels ca. 1 mm long; calyx lobes 5, drying black, 1.0–1.3 mm long, 0.7–0.8 mm wide, elliptic, valvate, reflexed at anthesis; stamens 5, the anthers subsessile, 2-locular, introrse, disk glands 5, intrastaminal. *Pistillate flowers* with calyx lobes 5, ovate-elliptic, ca. 1.5 mm long, acute, lightly hispidulous; stigmas nearly sessile, 3, thick. *Capsules* (not seen entire), apparently 3-lobed, with low reticulate ridges, lightly puberulent, apparently 6–7 mm diam.; seeds globose, cream mottled with reddish brown, smooth, 4–4.5 mm diam., ecarunculate.

This unusual species would key to sect. *Bia* (Klotzsch) Muell. Arg. in the treatment of Pax & Hoffmann (1919) on the basis of its five stamens and the presence of disk glands in the staminate flowers, but it seems hardly related to the other species of that section, which are characterized by their usually deeply cordate leaves (except *T. lessertiana* (Baillon) Muell. Arg.) and especially their robust, bipartite inflorescences with one branch staminate and the other pistillate. Were it not for the presence of the disk glands, however, *Tragia rubiginosa* might seem almost at home in the Cuban genus *Platygyne* Mercier, which Pax & Hoffmann distinguished from *Tragia* by unisexual (vs. androgynous) inflorescences, 5–15 (vs. 2–50 usually near the lower end of the range) stamens, globose hairy receptacles, free filaments, absence of a disk, and wide styles emarginate at the apex.

Liogier (1971: 132, 133) was spurred by his study of the Hispaniolan species *Tragia biflora* Urban, which closely resembles *Platygyne*, to investigate the relationship between *Tragia* and *Platygyne*. He found that the generic characters are intermixed in some species referred to *Platygyne*, and particularly in *T. biflora*, which has a globose, glabrous receptacle with 10–20 stamens and wide, but not emarginate, styles. His conclusion that *Platygyne* cannot be kept separate from *Tragia* is bolstered by the existence of *T. rubiginosa*, which has the five stamens and monoecious inflorescences typical of *Platygyne* but has a disk, flat glabrous receptacle, and nonemarginate styles. The inflorescences of *T. rubiginosa* are reminiscent of those of *T. biflora*, which likewise are monoecious, axillary, and somewhat reflexed, although considerably shorter and with a less pronounced peduncle. The leaves also seem similar but are longer, narrower, and less coarsely crenate in *T. rubiginosa*.

The specific epithet refers to the red-brown color of the flowers.

A REVISION OF *AMPELOCERA* (ULMACEAE)[1]

Carol A. Todzia[2]

Abstract

Ampelocera, a genus of Ulmaceae with nine species of low- to mid-elevation rainforest trees, occurs from Mexico to Brazil. This review deals with the systematics and nomenclature, including the description of three new species, *A. albertiae* Todzia from Colombia, *A. longissima* Todzia from Ecuador, and *A. macphersonii* Todzia from Panama, Colombia, and Venezuela. The taxonomic history of *Ampelocera* is outlined, followed by a key to the species. Brief descriptions and geographic ranges are provided for each species.

Ampelocera is a little-known genus of nine species of neotropical trees. Although a frequent component of some low- to mid-elevation neotropical forests (A. Gentry, pers. comm.), *Ampelocera* is poorly represented in herbaria because it is a large rainforest tree and because specimens are not readily identified and often are misfiled. *Ampelocera* is characterized by its large tree habit, buttressed trunk, oblique leaf bases, large number of stamens, bifid style, and asymmetrical drupaceous fruits. The genus ranges from central Mexico to Bolivia and southern coastal Brazil, and it occurs in the West Indies.

In preparing a treatment for the *Flora de Nicaragua*, the literature dealing with *Ampelocera* was reviewed along with all material available from the following herbaria: BM, CAS, F, K, LL, MO, NY, TEX, and US. Three new species as well as changes in the currently accepted nomenclature came to light. Since no summary of the systematics and geography exists, a revision of the genus is now presented. A short history of *Ampelocera* is outlined below, followed by a diagnostic key for the species and a review of their systematics and nomenclature.

Historically included in the Ulmaceae, the genus has been the subject of recent studies on embryology (H. Tobe, Kyoto University, Japan, in prep.) and pollen (M. Takahashi, in prep.) that indicate it is not well placed there. Although past authors have positioned the genus in the subfamily Celtidoideae based on its drupaceous fruit, *Ampelocera* is anomalous within the Ulmaceae by virtue of its 4–16 stamens. On the basis of a summation of evidence from various sources (morphology, anatomy, embryology, palynology, and flavonoid chemistry), Tobe considers *Ampelocera* best classified in a family of its own.

In 1847 Klotzsch described *Ampelocera* with one species, *Ampelocera ruizii*, from a Ruiz & Pavón collection. He placed his new genus near *Celtis*. Since then, *Ampelocera* has generally been aligned within the subfamily Celtidoideae of the Ulmaceae with *Celtis* L., *Trema* Lour., *Aphananthe* Planch., and *Gironniera* Gaudich., although Planchon (1873) considered its placement within the Ulmaceae doubtful due to the anomalous stamen number.

In 1937 Baehni created the genus *Plagioceltis* attributed to Mildbraed on the basis of unpublished notes on the Ruiz & Pavón type specimen at Madrid (Gentry, 1983). I strongly suspect that the unnumbered Ruiz & Pavón type specimen of *Plagioceltis dichotoma* is from the same collection as the type of *Ampelocera ruizii* Klotzsch (Ruiz & Pavón *s.n.*, B!) because both bear leaves and flowers of exactly the same maturity (very young, not fully expanded leaves; flowers at anthesis; no fruits).

Since *Ampelocera* was erected in 1847, ten species have been added to the original *A. ruizii*. The first addition, *Ampelocera cubensis*, was described by Grisebach based on a Wright collection. It was approximately 50 years before the next species of *Ampelocera*, *A. crenulata* Urban and

[1] I thank Guy Nesom for providing the Latin diagnosis, Doris Lee Tischler for the drawing, M. Kubala for field observations, Robbin Moran for help with references, and L. Albert de Escobar, A. Gentry, M. Nee, G. Rogers, and H. van der Werff for their helpful comments on the manuscript. I also wish to thank the curators of the following herbaria for borrowed material and/or help during visits: CAS, F, LL, K, BM, MO, NY, TEX, US.

[2] Dept. of Botany, University of Texas, Austin, Texas 78712, U.S.A.

A. hondurensis J. D. Smith, were described. Those species, however, were not members of *Ampelocera*, nor even the Ulmaceae, and are presently placed into synonymy in genera in the Flacourtiaceae and Achatocarpaceae, respectively. In 1925 Kuhlmann described *A. glabra* Kuhlm. and *A. verrucosa* Kuhlm. followed by *A. edentula* Kuhlm. (1940) and *A. latifolia* Ducke (1943) all from Brazil. In the protologue of the most recently described species, *A. macrocarpa*, Forero & Gentry (1984) indicated the need for taxonomic study of *Ampelocera*.

Morphology and Taxonomic Characters

Ampelocera species are small to large trees often with slender, channeled buttresses and smooth gray bark. The wood is light brown to cream-colored and hard.

LEAVES

The leaves of all species are pinnately veined except for those of *Ampelocera hottlei*, which are trinerved at the base. The texture of most leaves is coriaceous, but *A. cubensis* and *A. macphersonii* have chartaceous leaves. The leaves of *Ampelocera* are glabrous except for those of *A. cubensis*, which are sometimes softly puberulent beneath. Young leaves in most species are often many times larger than those on fertile branches. Young leaves of *A. hottlei* and *A. macrocarpa* are distinctive for their bright blue metallic color.

Nearly all leaves of *Ampelocera* are oblong to elliptic with characteristic oblique bases and attenuate apices. *Ampelocera cubensis*, *A. glabra*, and *A. ruizii* often have obscurely and coarsely dentate leaves. Petioles are usually thick and have a red flaky epidermis.

INFLORESCENCES

Ampelocera inflorescences are axillary, sometimes simple, usually compound dichasia or rarely are panicles of compound dichasia. In *A. glabra* the rachises are so short that the inflorescences appear fasciculate. The longest and most densely flowered inflorescences in the genus with up to 56 flowers are found in *A. longissima*. Inflorescences have perfect flowers and functionally staminate flowers, the latter being found lower on the inflorescence axis.

FLOWERS

Ampelocera flowers are small, cream-colored, yellow, or green and offer a limited number of characters. All dimensions provided in the descriptions are based on dried material. The perianth consists of a sepalar cup with four or five usually sparsely puberulent lobes. The lobes in *A. cubensis* are villous.

Stamen number varies from 4 to 16 with the staminate flowers often having fewer stamens (4–8) than the perfect flowers. Two kinds of filaments are found in the genus: relatively thick filaments expanded near the base and drying flat characterize *A. edentula* and *A. macrocarpa*, and relatively long, thin filaments that twist upon drying characterize the other seven species. The anther connective is extended beyond the thecae to form a strigose apicule. In the species with the short, broad filaments, the connective extension is very pronounced, while in those with long, thin filaments, the extension is smaller.

The ovary in *Ampelocera* is puberulent and oblong to globose. The two style branches are free to the base in most species, but in *A. cubensis* and *A. ruizii* they are united in the lower one-fourth. Staminate flowers often have cylindrical, ribbed pistillodes with the same vestiture as the ovaries in the perfect flowers.

Size and shape of the drupaceous fruits of each species of *Ampelocera* are quite distinctive. Generally the fruits of *Ampelocera* are yellow, asymmetrical, and transversely obovoid or ellipsoid; they vary from 0.6 to 2.2 cm long. The fruits may be glabrous (*A. glabra*, *A. longissima*), sparsely puberulent (*A. edentula*, *A. macrocarpa*), densely pubescent (*A. macphersonii*), or densely pilose (*A. ruizii*). *Ampelocera hottlei* fruits, the most unusual in the genus, are symmetrically oblong and velutinous with longitudinal striations. *Ampelocera macrocarpa* typically has pyriform fruits with an unusually thick endocarp.

USES

The wood of *Ampelocera* is hard and is used for firewood and lumber. In the Pichis Valley of Peru, the astringent bark of *A. edentula* is used by the Campa Indians to tattoo skin. The bark is wetted and then bound around the arm, where it ulcerates the skin and causes a painful eruption. A coloring agent is then applied to the ulceration and scar tissue forms (A. Gentry, pers. comm.).

Systematic Treatment

Ampelocera Klotzsch, Linnaea 20: 541. 1847.
TYPE SPECIES: *Ampelocera ruizii* Klotzsch.

Plagioceltis Milbr. ex Baehni, Contr. Field Mus. Nat. Hist., Bot. Ser. 13(2): 272. 1937.

Small to large trees with slender buttresses. Leaves petiolate, entire or coarsely dentate, usually glabrous, pinnately veined or palmately veined at base, with paired stipules. Inflorescences axillary, sparsely branched to much-branched dichasia, or the flowers fasciculate, with perfect flowers toward the apex and functionally staminate flowers toward the base; rachises 0.2–7.8 cm long with 2–57 flowers. Flowers white, yellow, or green; calyx with 4–5 lobes, these usually united in the lower half; petals absent; stamens 4–16; filaments 1–4 mm long, 0.5–1 mm broad, of two types, either thick and expanded near base and drying flat, or long, thin, and drying twisted; anther connective extended beyond the anther at the apex; ovary superior, unilocular with a single pendulous ovule, glabrous or pubescent; style branches 2. Fruits drupaceous, yellow or orange, globose, or oblong, or obovoid to transversely obovoid, with persistent stamens and style branches; seeds globose, with thick cotyledons.

KEY TO THE SPECIES OF *AMPELOCERA*

1a. Fruits strongly asymmetrical, broader than long (not known in *A. albertiae*); filaments slender throughout.
  2a. Leaves usually dentate, occasionally entire; inflorescences borne on leafless branches; style branches 3–5 mm long.
    3a. Leaf margins often revolute; filaments ca. 2 mm long; Cuba and Hispaniola ..... 2. *A. cubensis*
    3b. Leaf margins not revolute; filaments ca. 3 mm long; South America.
      4a. Inflorescence rachises 0.9–1.5 cm long with 8–23 flowers; calyx 2–2.5 mm long; fruits 1–1.2 cm tall, 1.2–1.6 cm broad, densely pilose; Peru, Bolivia, Amazonian Brazil ..... 9. *A. ruizii*
      4b. Inflorescence rachises 0.5 0.8 cm long with 4 9 flowers; calyx ca. 1.5 mm long; fruits 1.5 2 cm tall, 2–2.3 cm broad, glabrous; southeastern and central coastal Brazil ..... 4. *A. glabra*
  2b. Leaves always entire; flowers borne on leafy branches; style branches 1–2 mm long.
    5a. Inflorescences with 3–6 flowers; stamens ca. 16; leaves chartaceous, unevenly colored on drying; Panama, northern Colombia, northwestern Venezuela ..... 8. *A. macphersonii*
    5b. Inflorescences with (9)20 56 flowers; stamens 4–12; leaves subcoriaceous, uniformly colored on drying; Colombia (Valle), Ecuador.
      6a. Inflorescence rachises (2.7–)3.5–7.8 cm long, elongate, loosely flowered; ovary sparsely puberulent; Ecuador ..... 6. *A. longissima*
      6b. Inflorescence rachises 0.6–1.9 cm long, congested, densely flowered; ovary densely strigose; Colombia ..... 1. *A. albertiae*
1b. Fruits obovoid to globose, not strongly asymmetrical, longer than broad; filaments broadened basally.
  7a. Leaves trinerved at the base; style branches ca. 4 mm long; stamens ca. 16; fruits densely brown tomentose, with longitudinal striations; Mexico to Nicaragua ..... 5. *A. hottlei*
  7b. Leaves pinnately veined at the base; style branches 1 2 mm long; stamens (6–)8; fruits glabrous to sparsely puberulent, yellow; Honduras to Panama, South America.
    8a. Ovary densely puberulent; fruit with a thin endocarp; greater Amazon Basin in Surinam, Guyana, Brazil, Venezuela, Colombia, Ecuador, Peru, and Bolivia ..... 3. *A. edentula*
    8b. Ovary sparsely puberulent; fruit with a thick endocarp; Honduras to northern Colombia and northern Venezuela ..... 7. *A. macrocarpa*

1. Ampelocera albertiae sp. nov. TYPE. Colombia. Valle: carretera Cali–Buenaventura, km 24, 1,750 m, 15 Oct. 1982, *L. Albert de Escobar, J. Folsom, J. Brand & D. Sánchez 2788* (holotype, TEX; isotypes, HUA, MO). Figure 1.

Ampelocerae longissimae similis sed inflorescentiis densifloris et ovariis dense strigosis differt. Inflorescentiae saepe ad basim ramosissimae, floribus (9–)20–52, sepala 4, 1.5–2 mm longae, stamina 8(–12) in floribus perfectis, filamenta 1.5–2 mm longae, tenues, fructus ignotus.

Trees 4 m tall; younger branches very sparsely puberulent, reddish brown; older branches gray, glabrous; stipules 3–4 mm long, lanceolate, sparsely to moderately strigose. Leaf blades elliptic, 9–12 × 3–6 cm, the apex acute, the base attenuate, drying coriaceous, dull green to brown, uniformly colored, glabrous and smooth above and beneath, the margins entire; lateral veins 5–6, gradually arcuate, raised beneath; petioles 0.5–0.6 cm long, smooth, drying dark brown. Inflorescences axillary, short panicles on leafy branches, often much-branched at base, with perfect and functionally staminate flowers; rachises 0.6–1.9 cm long, densely flowered, with (9–)20–52 flowers, sparsely strigose. Flowers white, subtended by ovate, chartaceous, acute bracts ca. 1 mm long; calyx 1.5–2 mm long, the lobes 4, united at the base, glabrous to sparsely strigose, ciliate; stamens 8(–12) in perfect flowers, 4–8 in functionally staminate flowers, these with a strigose pistillode; filaments 1.5–2 mm long, slender throughout; anthers ca. 1 mm long, with the connective extending into a short strigose

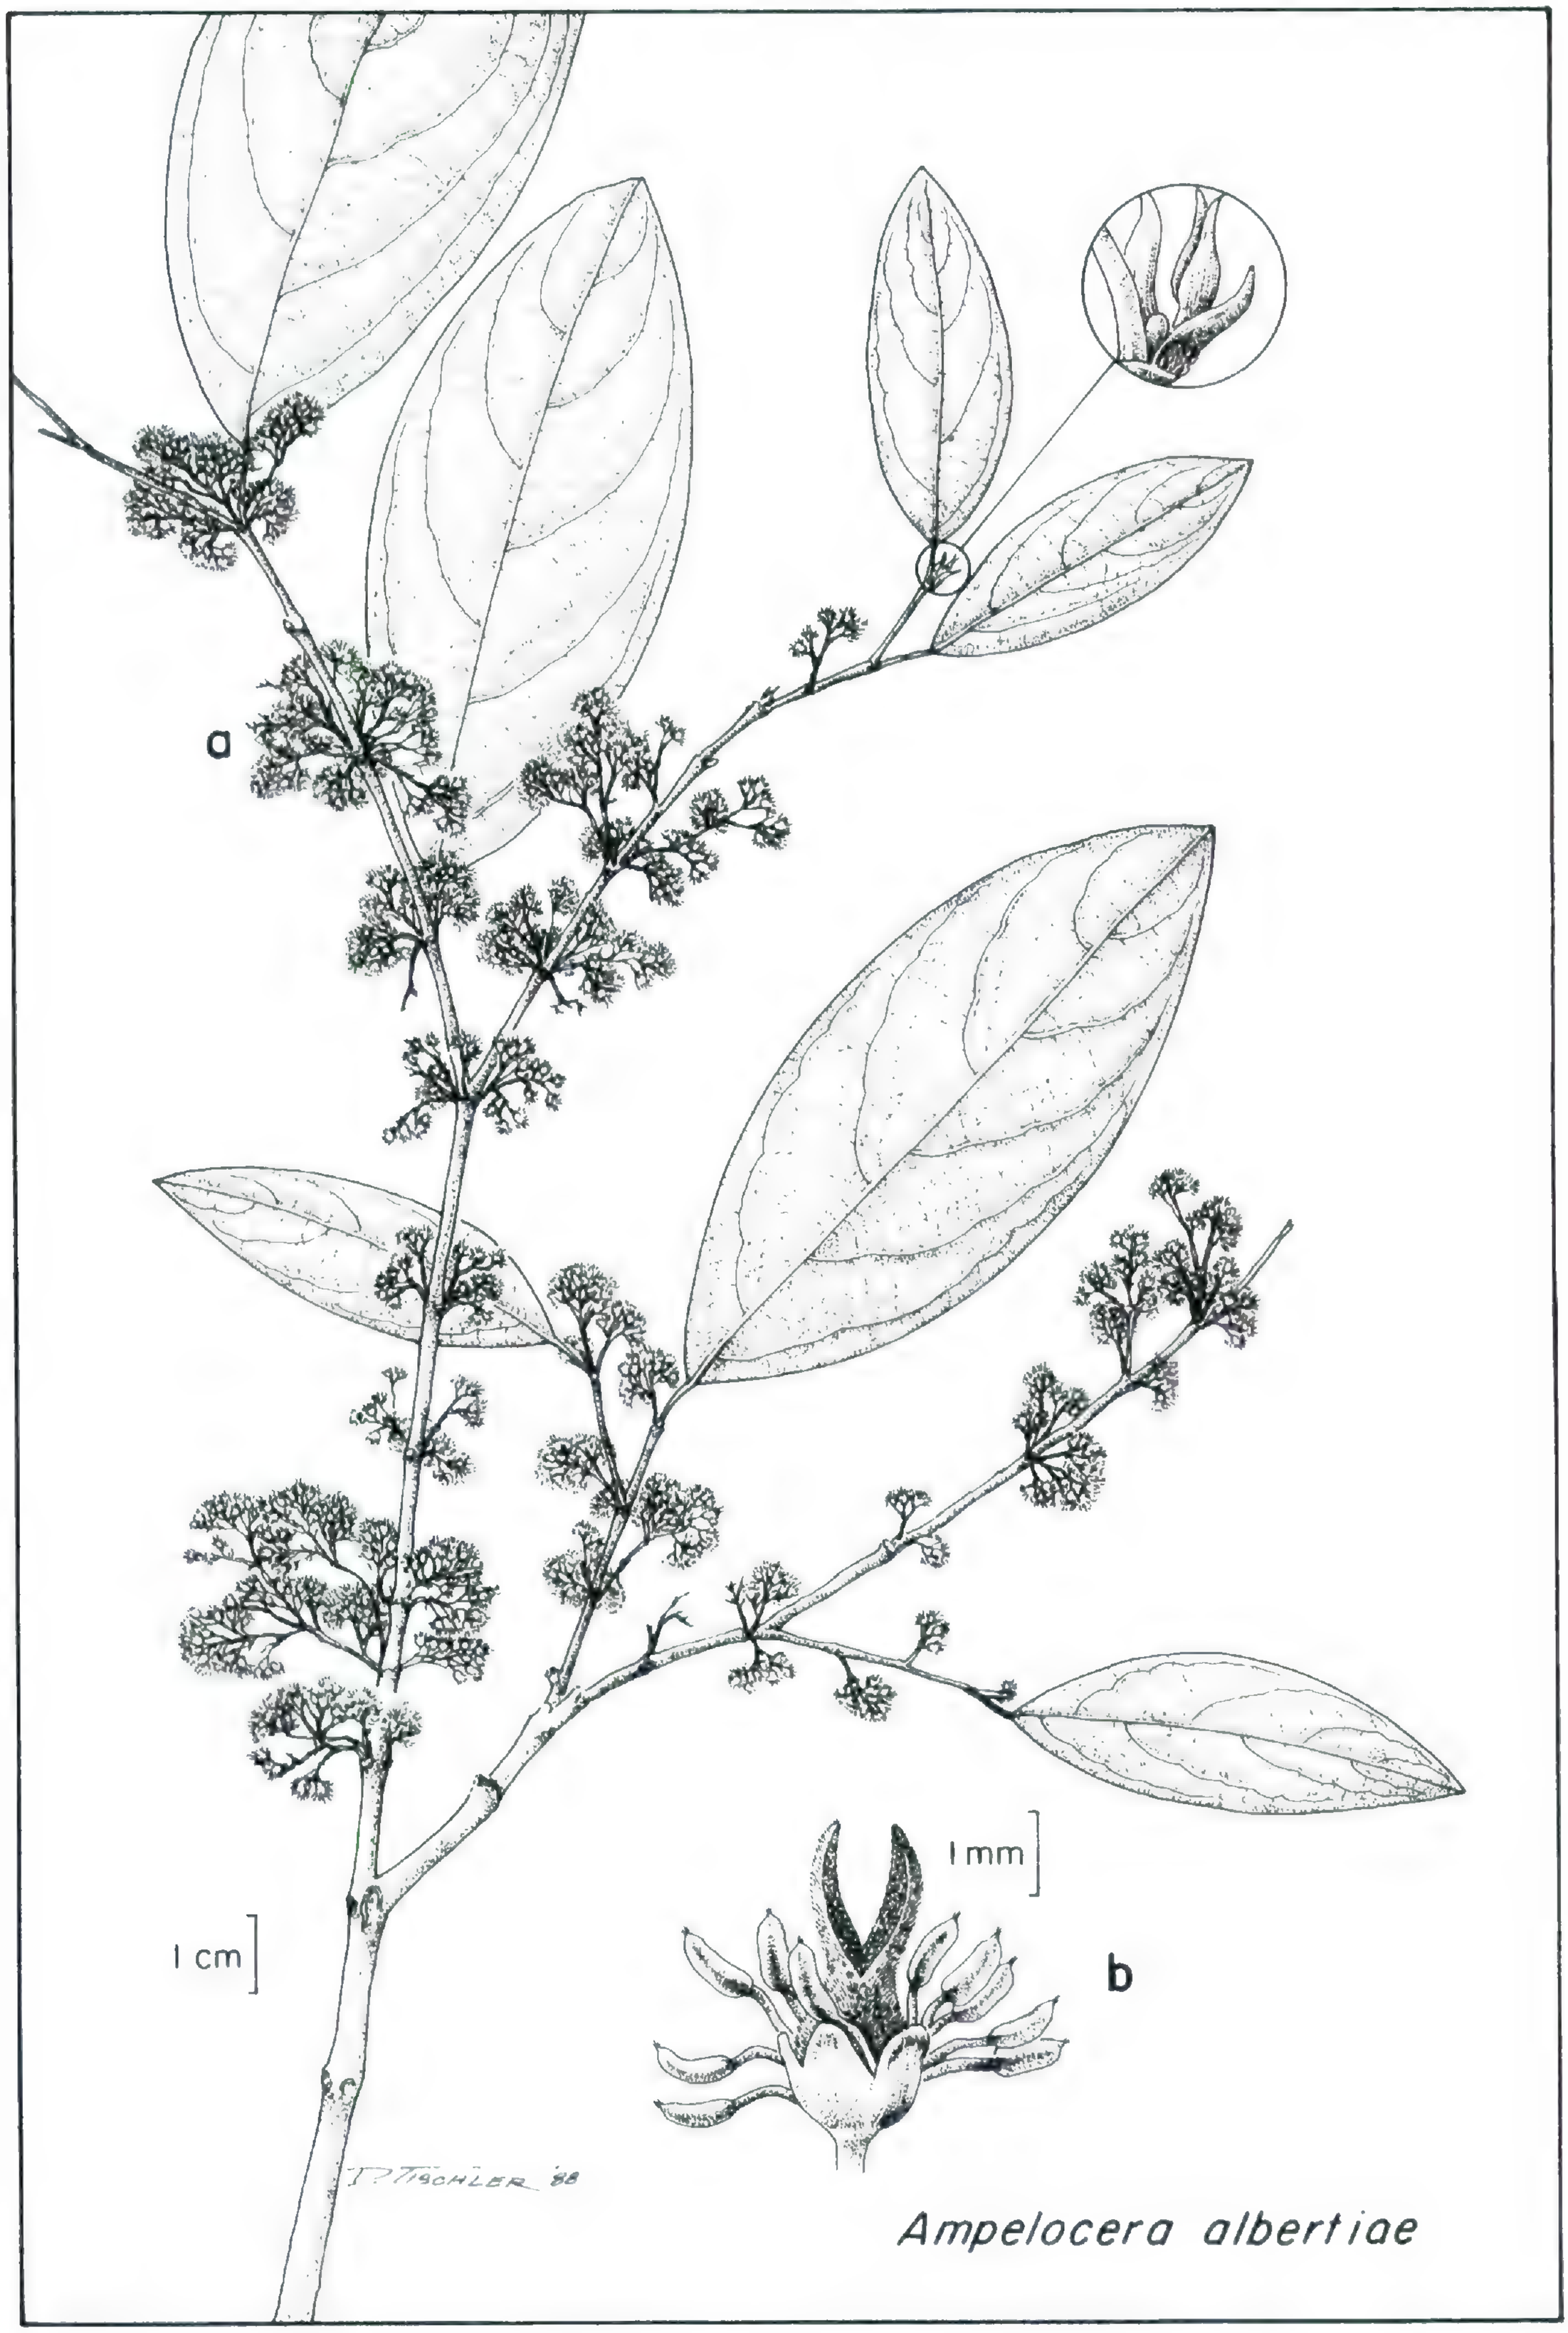

FIGURE 1. *Ampelocera albertiae.*—a. Fertile branch showing close-up of stipules.—b. Perfect flower. (From *Albert de Escobar et al. 2788* TEX.)

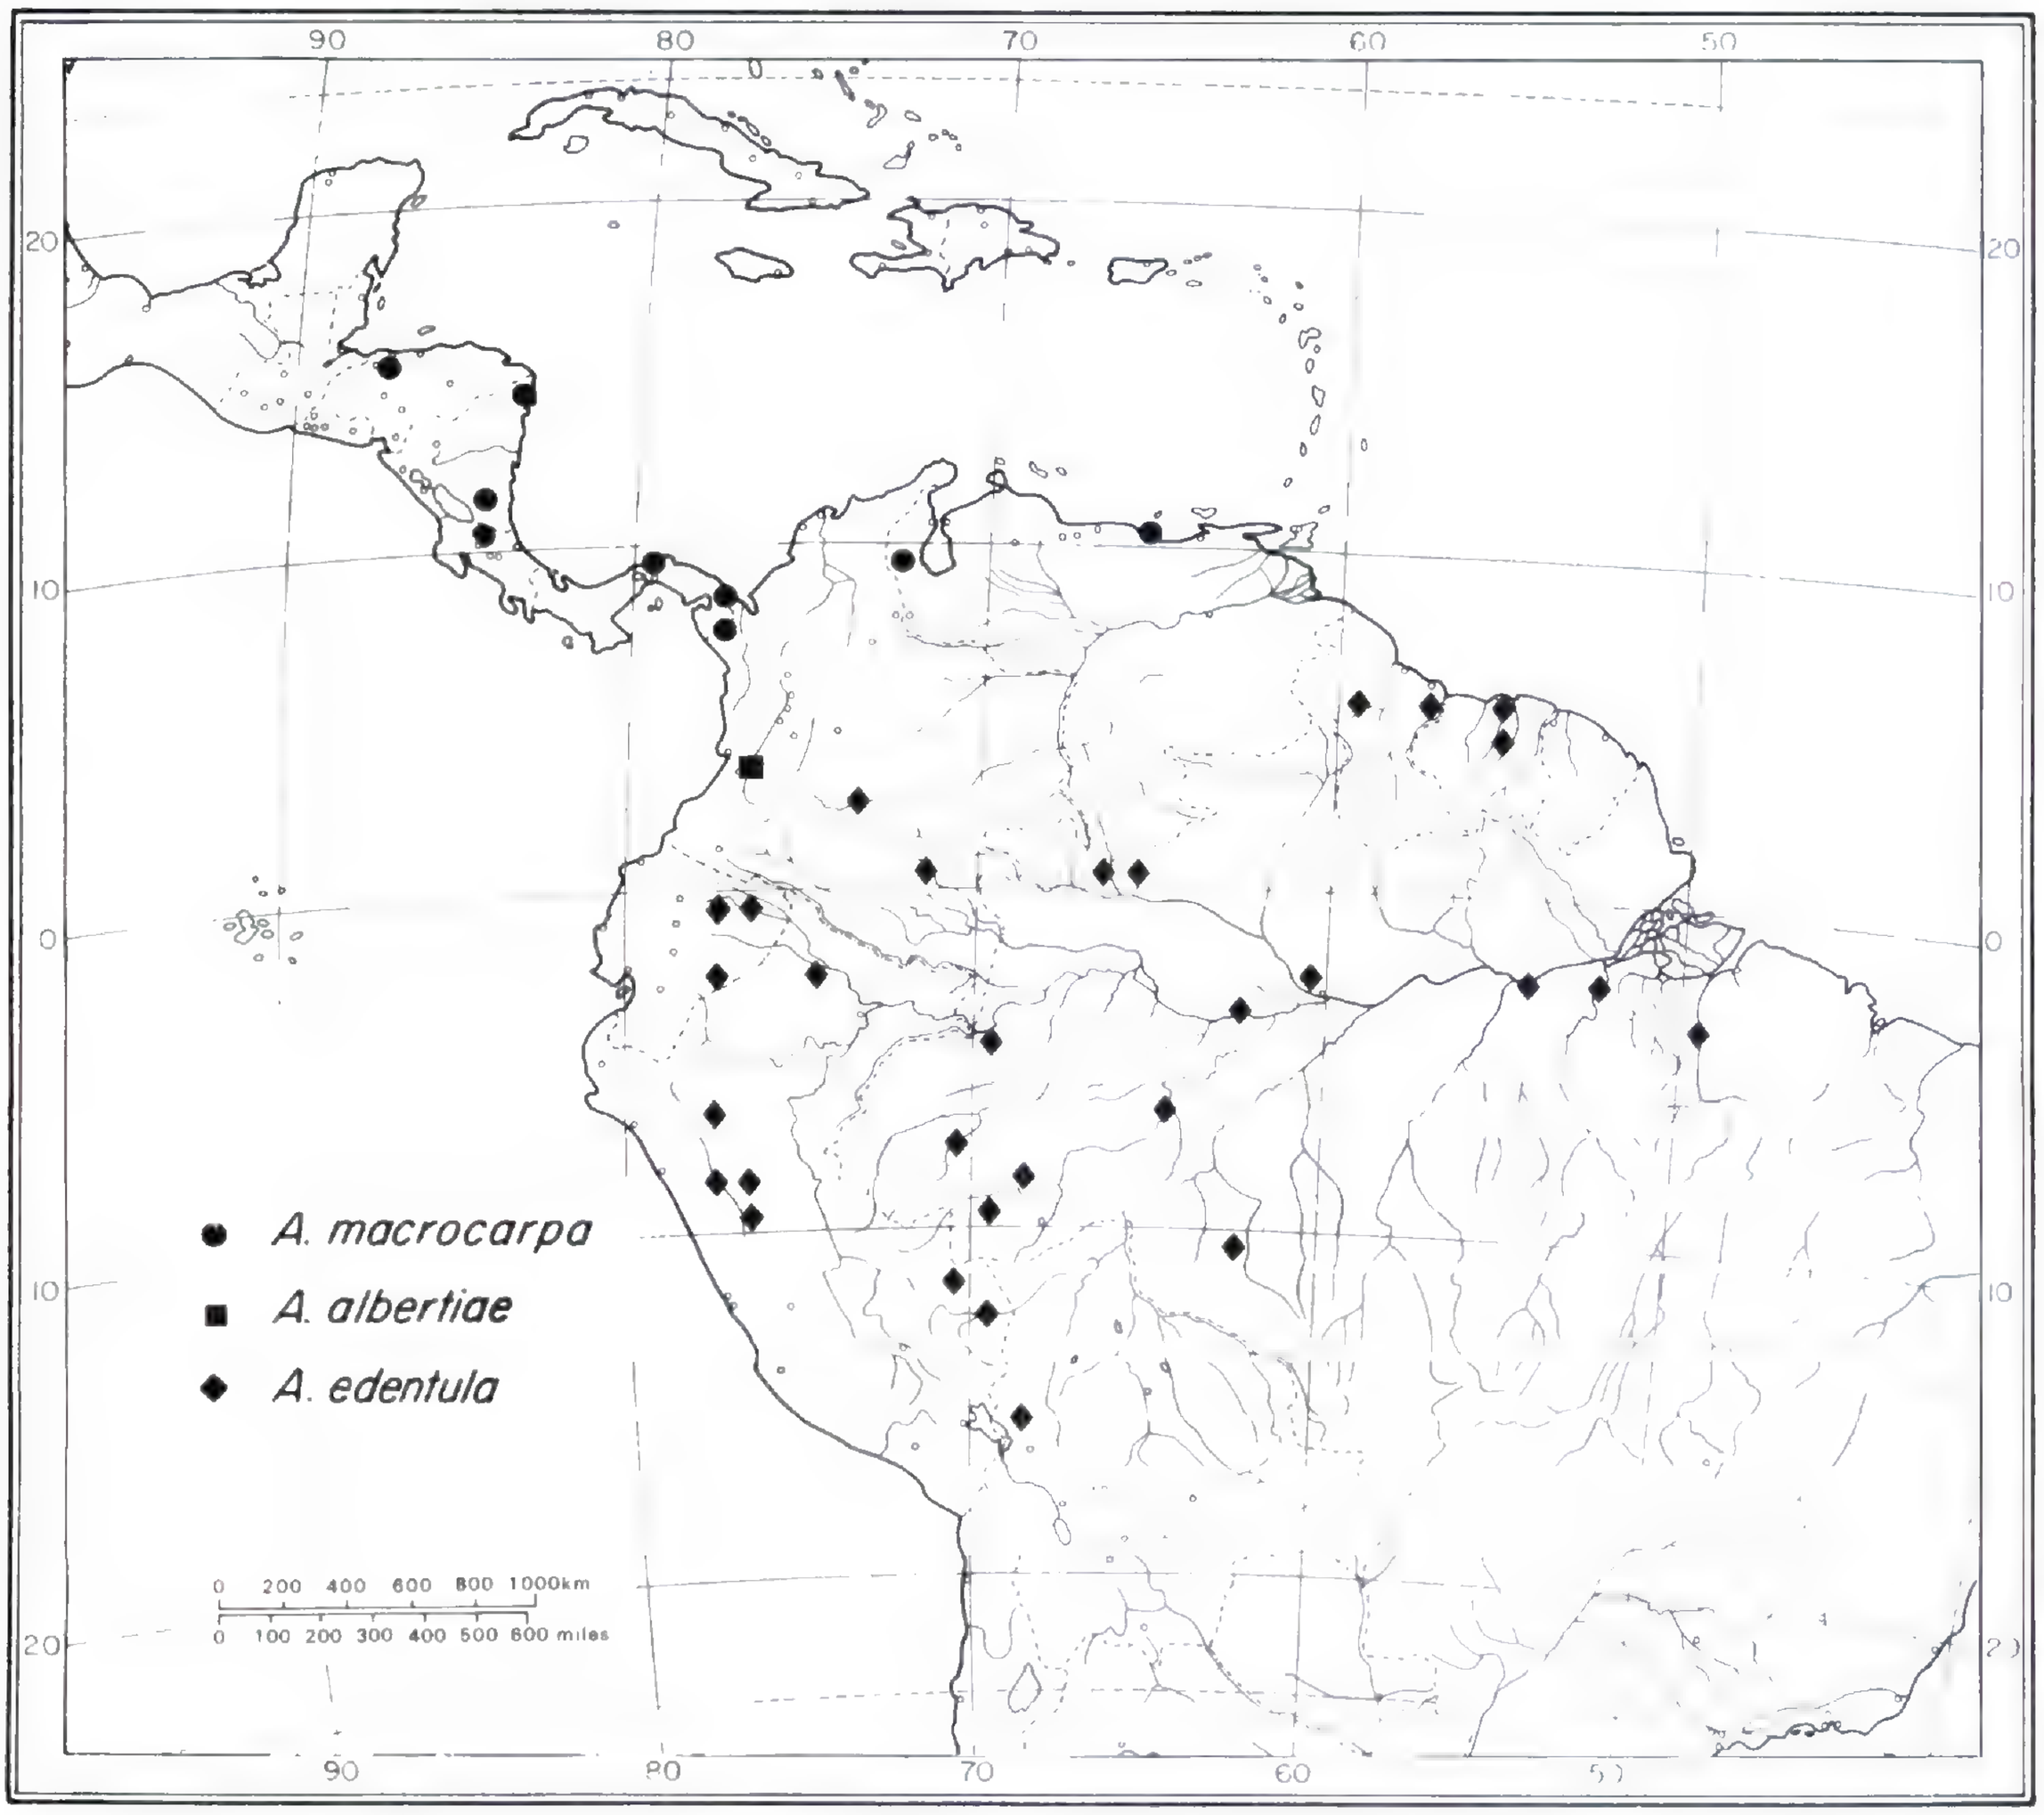

FIGURE 2. Distributions of *Ampelocera albertiae*, *A. edentula*, and *A. macrocarpa*.

apicule ca. 0.1 mm long; ovary densely strigose, the style branches 1.5–2 mm long, free to base. Fruit not seen.

Distribution, habitat, and phenology. This species is known only from the western slope of the western cordillera of Colombia (Fig. 2). Flowering is recorded in October.

Presently known from only one specimen, more collections are needed to understand the morphological variation and relationships of *Ampelocera albertiae*. *Ampelocera albertiae* is characterized by having entire leaves, densely flowered inflorescences on leafy branches, flowers with relatively thin filaments, and style branches 1–2 mm long. This species appears to be most similar to *Ampelocera longissima* but differs by having densely flowered inflorescences and densely strigose ovaries. The unusual, new species is named in honor of its discoverer, Dra. Linda Albert de Escobar, of the Universidad de Antioquia, Colombia (HUA), a student of Passifloraceae.

2. Ampelocera cubensis Griseb., Catalogus Plantarum Cubensium. 57. 1866. TYPE. Cuba. Pinar del Río: Loma de Rangel, 28 May 1863, *Wright 2222* (lectotype [designated by R. A. Howard (1988, Fiche 2, B 11)], GOET; isolectotypes, B, GH, GOET, K, MO).

Ampelocera pubescens C. Morton, Proc. Biol. Soc. Wash. 71: 153. 1958. TYPE. Cuba. Santa Clara: Limones, Soledad, Cienfuegos, 26 Apr. 1928, *J. G. Jack 6036* (holotype, US; isotypes, A—3 sheets, B, F (frag.), K, NY).

Trees 5–30 m tall; younger branches sparsely to densely puberulent, light brown; older branches glabrous, light gray to brown; flowering branches

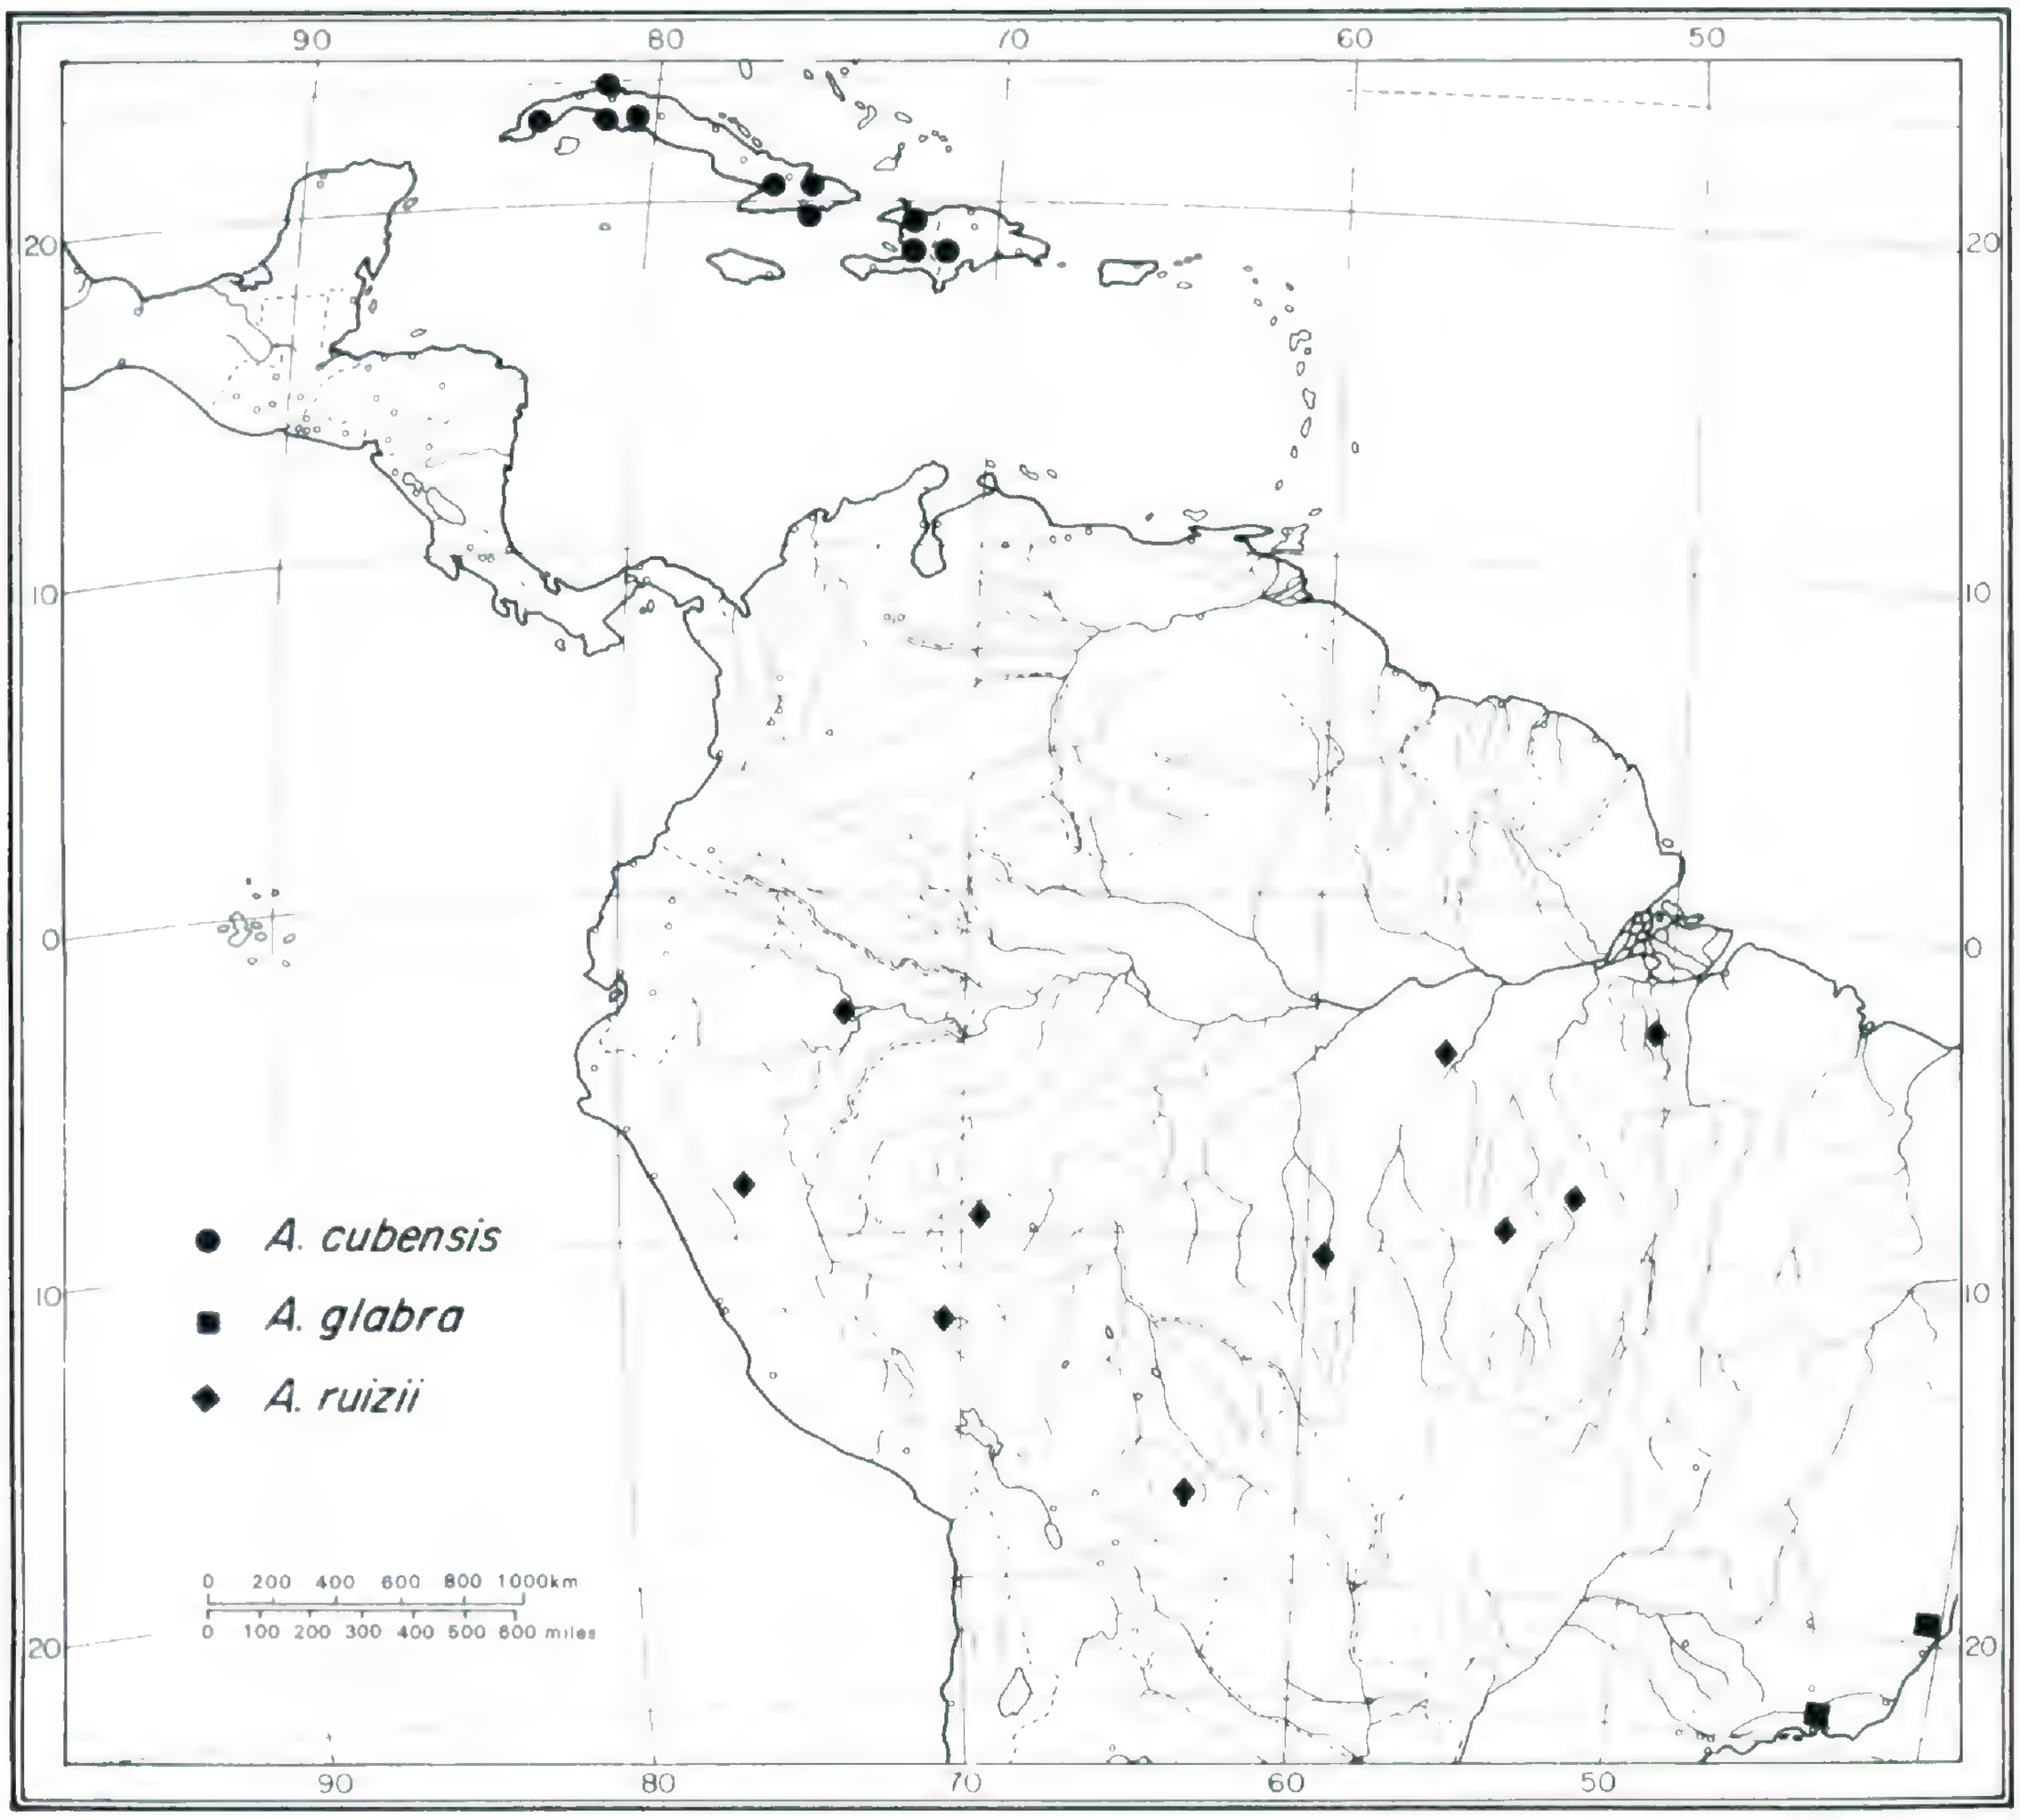

FIGURE 3. Distributions of *Ampelocera cubensis*, *A. glabra*, and *A. ruizii*.

with shortened internodes; stipules 2–5 mm long, lanceolate, sometimes falcate, acute, pilose. Leaf blades narrowly to broadly elliptic, 7.5–17 × 3.5–6(–9.5) cm, the apex gradually acuminate with the acumen 1–2 cm long, obliquely rounded at base, the margins entire, or obscurely dentate with 2–4 teeth per side, or obscurely crenulate, often revolute, drying chartaceous, light brown, the lateral veins 5–7, arcuate, smooth and glabrous above and beneath, the midvein puberulent to glabrous beneath; petioles 0.8–1.2 cm long, puberulent. Inflorescences axillary on leafless branches, fasciculate or in very short racemes with only perfect flowers; rachises 0.2–1 cm long with 2–5 flowers, glabrous to puberulent. Flowers (color not known) subtended by glabrous to sparsely puberulent bracts, the ovate bracteoles 2–3 mm long; calyx ca. 2 mm long, the lobes 4–5, united at base, pilose to villous; stamens 12–16; filaments ca. 2 mm long, linear, slender throughout; anthers 1–1.3 mm long, the connective slightly extended into an apicule; ovary sparsely puberulent, the style branches 3–4 mm long, connate in lower ca. 1 mm. Fruits yellow, asymmetrical, transversely obovoid, 0.8–1.3 cm long, 1–1.4 cm broad, puberulent; endocarp ca. 0.5 mm thick.

Common names. hueso de costa, jatia blanca (Cuba).

Distribution, habitat, and phenology. Uncommon in coastal thickets, limestone cliffs, and rocky woods in Cuba and on western Hispaniola (Fig. 3) from 0 to 300 m. Flowering apparently occurs February to June when the trees are leafless; fruiting specimens have been collected in April, May, July, and December.

Additional specimens examined. CUBA. HAVANA: near Playa de Mariano, Feb. 1922, *Bro. León 10677* (GH, NY, US); Sierra de Anafe, 8 Aug. 1923, *Bro. León 11486* (GH, NY). LAS VILLAS: on limestone outcrop of Potrero Seboruco at Gavilán, 1–20 July 1950, *Howard et al. 21* (A, NY). ORIENTE: Renté, Santiago Bay, July 1943, *Bro. Clemente 2984* (GH). Banes, Puerto Rico, 18 Nov. 1915, *Ekman 6629* (F, K, US); Palmarito de Cauto, 250 m, 2 May 1919, *Ekman 9626* (NY); Papayo, in hills, 21 Feb. 1919, *Ekman 9470* (LL, NY, US 2 sheets). PINAR DEL RÍO: Sierra de Anafe, 18 Dec. 1911, *P. Wilson 11398* (NY—3 sheets, US). SANTA CLARA: Limones, Soledad, Cienfuegos, 12 Mar. 1927, *Jack 4911* (A, NY, US); 3 Sep. 1927, *Jack 5396* (US); 7 Feb. 1928, *Jack 5934* (A—2 sheets, NY, US); 18 July 1929, *Jack 7490* (A, NY, US); Bartolina woods, S coast of eastern Tapata, 1 Aug. 1930, *Bro. León 14625* (GH, NY). DOMINICAN REPUBLIC. SANTO DOMINGO: Peninsula de Barahona, top of Cerro Jean-Josè, ca. 300 m, 23 Sep. 1926, *Ekman 7044* (GH). HAITI: L'ARTIBONITE: Massif des Cahos, Dessalines, limestone cliffs at Case-à-Roche, 13 Mar. 1925, *Ekman 3506* (LL); Gonâve Island, Anse à Galets, Aug. 1927, *Eyerdam 214* (A, GH, NY, US).

This species is characterized by relatively small, thin, sparsely dentate leaves; short, fasciculate inflorescences that are borne on leafless branches; style branches 3–4 mm long; linear filaments; and small, puberulent, strongly asymmetrical fruits. *Ampelocera cubensis* is closely related to *A. glabra* from central coastal and southeastern Brazil and *A. ruizii* from Amazonian Brazil, Peru, and Bolivia. It differs from *A. glabra* by having smaller fruits and less prominently dentate leaves and differs from *A. ruizii* by having shorter inflorescences with 2–5 (vs. 8–23) flowers and by having sepals 1.5 (vs. 2–2.5) mm long.

Morton (1958) described *Ampelocera pubescens*, distinguishing his new species from *A. cubensis* by the vestiture of the lower leaf surface and the length of the stipules (4.5–6 mm in *A. pubescens* vs. 3 mm in *A. cubensis*). I can find no other characters to corroborate the recognition of two taxa, and, in fact, vestiture of material annotated as *A. pubescens* by Morton, including the type (*Jack 6036*), ranges from densely to sparsely pilose.

3. Ampelocera edentula Kuhlm., Annais Prim. Reu. Sul. Amer. Bot. 3: 75. 1940. TYPE. Brazil. Pará: "In silva collina inter locos Piquiatuba et Cipoal," 18 Jan. 1933, *Ducke s.n.* (RB # 24.565) (holotype, RB, n.v.; isotypes, K, US).

Ampelocera latifolia Ducke, Trop. Woods 76: 15. 1943. TYPE. Brazil. Amazonas: Esperança, boca do Javary, 29 Oct. 1942, *Ducke 1039* (holotype, RB, n.v.; isotypes, MG, MO, NY, US).

Trees 12–30 m tall, up to 90 cm dbh, with triangular buttresses 1.5–3 m high; young branches dark reddish brown, glabrous to puberulent, lenticellate, smooth; older branches light grayish brown, with exfoliating bark; stipules 2–6 mm long, narrowly to broadly lanceolate, acute, strigose. Leaf blades elliptic to oblong-elliptic, 8–26(–35) × 3.5–12 cm, apex acuminate with tips 0.2–1.2 cm long, the base rounded, cuneate to oblique, with margins entire, lustrous above, glabrous, drying smooth above and beneath, dull green to brown, pinnately veined; lateral veins 5–7, arcuate, raised beneath; petioles 0.5–1.4 cm long, glabrous or with a red flaky epidermis. Inflorescences 1–2 per axil on leafy branches, short, much-branched, densely flowered panicles, with staminate and perfect flowers; rachises 0.8–2.8 cm long, branching almost to the base, densely flowered, with 6–27(–55) flowers, puberulent. Flowers white to greenish yellow, subtended by bracts 0.5–2 mm long, these reddish, ciliate, ovate, acute, chartaceous; pedicels 0.5–1 mm long, narrower than the rachis and flower base; calyx 1.5–2 mm long, the lobes 4, united in lower half, glabrous to sparsely puberulent; stamens (6–)8 in perfect and staminate flowers; filaments 3–4 mm long, broadened basally; anthers ca. 1 mm long, often curved inward, with the connective extended into an apicule 0.5–1 mm long; ovary in perfect flowers densely puberulent, oblong, 2–3.5 mm long, with style branches 1–1.5 mm long; pistillode in staminate flowers oblong, strigose at the apex and with 5–6 strigose ridges. Fruits yellow, globose to oblong, only slightly asymmetrical, glabrous to sparsely puberulent, scabrous, (0.8–) 1.6–2.2 cm long, 1–1.7 cm broad; endocarp thinner than 0.5 mm.

Common names and uses. Nina-caspi (Peru: San Martín). The fiber of the bark is strong, and when bound around the arm it causes painful eruption; it is toxic and vesicans. The fruit is hypnotic. (Data fide *Woytkowski 5449.*)

Distribution, habitat, and phenology. This species is found throughout the Amazon Basin from near sea level to 750 m in Surinam, Guyana, Venezuela, Brazil, Colombia, Ecuador, Peru, and Bolivia (Fig. 2) in primary tropical moist forest and nonflooded and flooded riverine forests. Flowering and fruiting apparently occur throughout the year.

BOLIVIA. LA PAZ: Prov. Larecaja, Tuiri, near Mapiri (on left bank of Río Mapiri), 490 750 m, 12–30 Sep. 1939, *Krukoff 10732* (A, F, K, MO, US), *10727* (A, F, K, MO, US).

Ampelocera edentula is characterized by having flowers with eight stamens; broad filaments with a pronounced terminal extension of the connective; and large yellow, globose, symmetrical fruits. This species is most closely related to *A. macrocarpa* from which it differs in having generally oblong fruits and a thin endocarp (vs. globose fruits and a thick endocarp).

In his description of *Ampelocera latifolia*, Ducke (1943) stated that his new species might be just an upper-Amazonian variant of *A. edentula*. The fruit on the type of *A. latifolia* is distinctly oblong while that on the type of *A. edentula* is smaller and round. This variation, however, may reflect only a difference in fruit maturity, and since I could find no other consistently correlated characters, *A. latifolia* is placed into synonymy with *A. edentula*.

Although *Ampelocera edentula* occurs throughout a broad geographic area in the Amazon Basin, it is poorly represented in herbaria, and consequently, its morphological variation is difficult to assess. Leaves are generally shorter on fertile branches, 12–20 cm long, while sterile branches have leaves up to 30 cm long. Some collections from Peru and Bolivia (*Schunke 4395*, *Woytkowski 7307* (Perú: Dept. San Martín); *Krukoff 10727* (Bolivia: La Paz)) have leaves up to 35 cm on fertile branches. These populations differ further from typical Brazilian *A. edentula* in having shorter petioles, more oblique leaf bases, and more pubescent fruits. A sterile specimen from Peru (Dept. Loreto: Prov. Requena, Jenaro Herrera, Río Ucayali, 73°45′W, 4°55′S, 22 Feb. 1987, *Gentry et al. 56289* (MO)) is unusual in having sparsely pubescent stems, petioles, and the lower surface of the primary and secondary veins. As more specimens become available, the variation presently included in *A. edentula* may warrant recognition of other taxa.

4. **Ampelocera glabra** Kuhlm., Arch. Jard. Bot. Rio de Janeiro 4: 351, pl. 28. 1925. TYPE. Brazil: "Rio de Janeiro ad urbem in selva loco Fabrica Alliança," 8 Nov. 1922, *Kuhlmann 6794* (holotype, B; isotypes, K, MO, US).

Trees 3–20 m tall, with a spreading crown; trunk brown, up to 66 cm diam.; older stems gray, glabrous; younger stems brown, glabrous; stipules ca. 5 mm long, lanceolate, glabrous or sparsely pilose. Leaf blades elliptic, 7.5–14 cm long, 2.7–7.2 cm wide, the apex acuminate, the tip 0.3–1.5 cm long, obliquely rounded at base, the margins dentate with 4–6 teeth, seldom entire, smooth, glabrous, drying subcoriaceous, the lateral veins 5–8, straight in lower ¾, slightly arcuate near margin; petioles 0.5–1 cm long, glabrous, drying dark brown. Inflorescences fasciculate or very short racemes or cymes, axillary on leafless stems, with perfect and staminate flowers having rudimentary pistils; rachises 0.5–0.8 cm long, sparsely puberulent, with 4–9 flowers. Flowers green, subtended by bracts ca. 1.5 mm long, glabrous to sparsely pilose; calyx ca. 1.5 mm long, the lobes 4, united at the base, ovate, sparsely pilose; stamens 16 in bisexual flowers, 12–14 in functionally staminate flowers; filaments ca. 3 mm long, slender throughout, with the connective extended into an apicule ca. 0.3 mm long; anthers 1–1.5 mm long; ovary sparsely puberulent and verrucose, the style branches ca. 4 mm long. Fruits yellow, asymmetrical, transversely obovoid, 1.5–2 cm tall, 2–2.3

cm broad, glabrous, with persistent style branches; endocarp thin.

Common name. Mentira (Brazil).

Distribution, habitat, and phenology. This species occurs in primary forest in southern coastal Brazil (Fig. 3). Flowering August to November usually on leafless branches.

Additional specimens examined. BRAZIL. ESPIRITO SANTO: Reserva Florestal da CVRD, Linhares, Est. Gavea, ant. X-2, KM 20,790, 20 Aug. 1979, *Foli 98* (MO). MINAS GERAIS: Distr. Rio Branco, retiro de Antonio Avelino, 750 m, 27 Dec. 1930, *Mexia 5456* (MO). RIO DE JANEIRO: cultivadad no Horto Florestal da Gávea, 7 Jan. 1932, *Victorio s.n.* [RB no. 139428] (B); Huto Florestal, 19 Jan. 1928, *Kuhlmann s.n.* [RB no. 139426] (F); Mata das Obras Públicas, 23 Dec. 1926, *Kuhlmann s.n.* [RB no. 139430] (F, US).

Ampelocera glabra is distinguished by its small fascicles of flowers; large, strongly asymmetrical, glabrous fruits; and toothed leaves. It is clearly most closely related to and can be easily confused with *A. ruizii* but is geographically disjunct. The straight instead of arcuate lateral veins in *A. glabra* are distinctive in the genus.

5. Ampelocera hottlei (Standley) Standley, Trop. Woods 51: 11. 1937.

Celtis hottlei Standley, Trop. Woods 20: 20. 1929. TYPE: Honduras. Yoro, near Progreso, 4 Apr. 1929, *Hottle 32* (holotype, F).

Trees 10–30 m tall; trunk 10–50 cm dbh, with narrow buttresses, ca. 2 m tall; crown subglobose or spreading; bark smooth, white to gray with dark lenticels, hard, with a sweet odor; sapwood creamy yellow to light brown; branches light brown-gray, lenticellate; stipules ca. 4 mm long, linear-lanceolate, puberulent. Leaf blades oblong to elliptic, (7–)8.5–16(–26) × (2.6–)3.3–8(–10.5) cm, the apex acuminate with an acumen 0.2–3 cm long, obliquely attenuate to rounded at base, the margins entire, drying chartaceous to subcoriaceous, dull dark green above, dull light green beneath, the young leaves blue to purple, glabrous and smooth above and beneath, the lateral veins 3–4(–5), arcuate, only slightly raised beneath, the base palmately veined with basal pair arising at the petiole; petioles 0.6–1.2 cm long, glabrous, minutely verrucose, usually drying dark brown. Inflorescences axillary on leafy branches, 1–2.5 cm long, compound dichasia with perfect flowers toward the apex and functionally staminate flowers toward the base; rachises 0.7–1.5 cm long with 8–17 flowers, puberulent. Flowers purplish to yellowish green, subtended by puberulent bracteoles 1–2 mm long; calyx 1–2 mm long, the lobes 5, united at base, puberulent abaxially; stamens ca. 16 in perfect flowers, ca. 8 in staminate flowers; filaments ca. 2 mm long, linear-lanceolate, broadened basally; anthers ca. 1 mm long, anther connective extended ca. 1 mm into a puberulent apicule; ovary puberulent, the style branches ca. 4 mm long, united in lower 2–3 mm. Fruits yellow, symmetrical, obovoid, 1.2–1.5 cm tall, 1–1.2 cm wide, velutinous, with persistent style branches; endocarp ca. 1 mm thick.

Common names and uses. Mexico: coquito, cautivo, guaya, ojoche blanco, popo mojo. Belize: bullhoof, luin. Guatemala: luín, tisón. El Salvador: tisón. Nicaragua: cuscano, yayo. The wood is used for house construction and railroad ties.

Distribution, habitat, and phenology. This species occurs from central Mexico to Nicaragua (Fig. 4) in primary, undisturbed rainforest or tropical wet forest, sometimes on limestone. Flowering reported from February and fruiting from March to June.

Ampelocera hottlei is represented by the most collections and thus is the best-known species in the genus. Unlike other species, description of the trunk, bark, and sap is available from collection data. It is distinguished from all other species by its trinerved leaf base, and obovoid, densely pubescent, longitudinally lined fruits. As with *A. macrocarpa*, the young leaves are bright metallic blue.

6. **Ampelocera longissima** Todzia. TYPE. Ecuador, Napo: Estación Biológica Jatun Sacha, Río Napo, 8 km al E de Misahuallí 01°04′S, 77°36′W, 450 m, 28 Dec. 1987, *Neill, Gentry & Manning 8135* (holotype, TEX; isotype, MO). Figure 5.

Inflorescentiae pro genere longissimae, (2.7–)3.5–7.8 cm longae, flores 33–56. Sepala 4 glabra in dimidio inferno connata, stamina 8–10 filamentis ca. 3 mm longis tenuibus. Ovaria sparsim puberula. Rami styli 1–2 mm longi. Fructus leviter lutei transverse obovoidei glabri endocarpium tenuissimum.

Trees up to 20 m tall, with a large, round crown, and shallowly channeled buttresses to 1 m high; bark light gray; wood cream-colored to light brown; young branches very minutely puberulent, dark brown; older branches glabrous, gray; stipules 2–3 mm long, narrowly triangular. Leaf blades elliptic, 8.5–17.4 × 3.5–7.1 cm, the apex acute to gradually acuminate, the tips up to 1 cm long, attenuate at the base, rarely oblique, drying subcoriaceous, green to light brown, uniformly colored, smooth and glabrous above and beneath, the margins entire; lateral veins 4–6, arcuate; petioles 5–14 mm long, glabrous, smooth, and dark brown, becoming flaky and gray with age. Inflorescences axillary on leafy branches, flat-topped panicles or compound dichasia, often curving upward; rachises (2.7–)3.5–7.8 cm long, very minutely puberulent, loosely flowered, with 33–56 flowers. Flowers bisexual or staminate with pistillodes, light green; sepals 4, glabrous, connate in lower half; stamens 8–10; filaments ca. 3 mm long, linear, slender throughout; anthers ca. 1 mm long; ovary sparsely puberulent; style branches 1–2 mm long, papillate on inner surface, glabrous to sparsely strigulose on outer surface. Fruits light yellow, asymmetrical, transversely obovoid, 0.6–1 cm tall, 1–1.4 cm broad, glabrous, with persistent style branches; endocarp very thin, thinner than 0.5 mm.

Distribution, habitat, and phenology. This species is known only from Napo Province in Amazonian Ecuador (Fig. 4) in primary forest. Flowering reported in March on leafy branches; fruiting reported in January, May, and December.

Additional specimens examined. ECUADOR. NAPO: Reserva Biológica Jatun Sacha, Río Napo, 8 km al E de Misahuallí, 01°04′S, 77°36′W, 450 m, 19–28 Mar. 1987, *Cerón 973* (MO, TEX); 8 Nov. 1987, *Cerón 2633* (MO, TEX); 18–30 May 1985, *Palacios et al. 519* (MO); 25 Jan. 1986, *Palacios & Neill 965* (MO).

Ampelocera longissima is distinctive in having the longest inflorescences known in the genus, as well as glabrous, asymmetrical, transversely obovoid fruits. Vegetatively, *A. longissima* is somewhat similar to *A. edentula*, which grows in the same area, but can be separated easily by the latter's shorter inflorescences and pubescent, symmetrical fruits.

7. Ampelocera macrocarpa Forero & A. Gentry, Phytologia 55: 365. 1984. TYPE. Colombia. Chocó: upper Río Truandó between La Teresita and mouth of Río Ramón, 20 Jan. 1974, *Gentry 9436* (holotype, COL, n.v.; isotypes, MO, NY).

Trees 10–30 m tall; trunk to 50 cm dbh; younger branches sparsely puberulent; older branches glabrous; stipules ca. 6 mm long, linear-lanceolate, sparsely puberulent. Leaf blades oblong to elliptic, 8–22 × 3.7–10 cm (sapling leaves 22–38 cm long), the apex acute to acuminate with tips 1–3 cm long, very strongly oblique, base rounded to subcordate, the margins entire, drying coriaceous, dull green to brown, glabrous and smooth above and beneath, pinnately veined; lateral veins 4–11, arcuate, raised beneath; petioles 0.6–1 cm long, with a flaky red epidermis. Inflorescences axillary on leafy branches, compound dichasia with perfect flowers toward the apex and functionally staminate flowers at the base; rachises (1.8–)2.5–3.7 cm long, with 11–34(–57) flowers, glabrous, sometimes purple. Flowers green, subtended by minute floral bracts, ca. 1 mm long, ovate, acute, chartaceous; sepals 4–5, 1–2.5 mm long, united at base, glabrous; stamens 8 in perfect flowers, 4–6 in staminate flowers; filaments 1.5–2 cm long, broadened basally; anthers ca. 1 mm long, the connective extended into a short apicule less than 0.5 mm long; ovary in perfect flowers sparsely puberulent, with style branches 1–2 mm long; pistillode in staminate flowers cylindrical with longitudinal strigose ribs. Fruits yellow, globose or drying pyriform, 1.8–2.2 cm diam., essentially symmetrical, glabrous or very sparsely strigose, scabrous, with persistent style branches ca. 2 mm long; endocarp 1–2 mm thick.

Common names. Nicaragua: cuscano, yayo. Costa Rica: rescaldo.

Distribution, habitat, and phenology. This species occurs in the Atlantic lowland rainforest of Honduras, Nicaragua, Costa Rica, Panama, northern Venezuela, and northwestern Colombia (Fig. 2). It has been reported in second growth evergreen forest and on limestone. Flowering specimens have been collected in February; fruiting collections are known from January, March, May, and August.

Additional specimens examined. HONDURAS. ATLÁNTIDA: Lancetilla Valley, near Tela, 20–600 m, 6 Dec. 1927–20 Mar. 1928, *Standley 53125* (F), *54159* (F). NICARAGUA. Ampelocera macrocarpa is characterized by its large fruits with a very thick endocarp, relatively short petioles with flaky red epidermis, and short style branches. The leaves of this species are bright metallic blue when young and have strongly oblique bases. On saplings and young branches the leaves are extremely long and narrow (22–38 cm long). *Ampelocera macrocarpa* appears to be most closely related to *A. edentula* by virtue of the characters given in the key.

8. Ampelocera macphersonii Todzia, sp. nov. TYPE. Panama. Panamá: Canal Area, on hilltop W of canal and Panama City, 8°50′N, 79°34′W, 300 m, 3 May 1987, *McPherson & Stockwell 10901* (holotype, MO; isotypes, NY, PMA, TEX). Figure 6.

Arbores foliis ellipticis chartaceis. Inflorescentiae breves, racemi ramosi vel simplices, 0.8–1.2 cm longi, flores 3–6. Sepala 4, in dimidio distali villosa vel sericea, stamina ca. 16, filamenta 1.5–2 mm longa. Fructus aurantiaci, dense pubescentes, ramis styli persistentibus, transverse obovoidei valde asymmetrici, endocarpium tenue.

Trees up to 20 m tall; younger branches dark brown, puberulent; older branches gray to brown, glabrous, sparsely lenticulate; stipules narrowly triangular to lanceolate, 2–4 mm long, villous. Leaf blades elliptic, 7.5–21 × 4–7 cm, the apex acute or with acuminate tips up to 1.2 cm long, the base rounded to subcordate, sometimes oblique, the margins entire, dark green and shiny above, paler beneath, drying chartaceous, smooth and glabrous above and beneath, light brown to tan, unevenly colored on drying, lateral veins 5–10, arcuate; petioles 0.5–1 cm long, sparsely puberulent, with a smooth epidermis, drying dark brown. Inflorescences axillary, short, simple or compound dichasia, often paired at the node, borne on leafy branches; rachises 0.8–1.2 cm long, strigose to sparsely villous, with 3–6 flowers; subtending floral bracts 1–2 mm long, glabrous. Flowers not seen (the following description based on persistent floral parts on fruits); calyx ca. 2 mm long, the lobes 4, villous to sericeous in distal half; stamens ca. 16; filaments 1.5–2 mm long, linear-lanceolate, slender throughout; anthers ca. 1–1.5 mm long, connective not extended. Fruits yellow to orange, strongly asymmetrical, transversely obovoid, 1.2–1.6 cm long, 1.6–1.8 cm broad, densely pubescent, sweet, with persistent style branches 2 mm long; endocarp thin, less than 0.5 mm thick.

Common name and uses. Panama: Carasuma. Used as firewood.

Distribution, habitat, and phenology. This species occurs in Panama, northern Colombia, and northwestern Venezuela (Fig. 4). It is found in undisturbed deciduous forest and in moist forest, sometimes on limestone. Fruiting is in May, June, and October on leafy stems.

Representative specimens examined. PANAMA. DARIÉN: 110 mi. from Bayano Dam Bridge, vicinity of Canglón, trail to S from road to good forest, 50 ft., 14 May 1980, *Antonio 4568* (MO); Loma Piriauqe, 14 Apr. 1966, *Duke 8108* (MO); Río Pucro, below village of Pucro, 23 June 1967, *Duke 13126* (MO). Ampelocera macphersonii is distinctive in having entire leaves and small, orange, strongly asymmetrical, transversely obovoid fruits. By virtue of its 16 stamens it is allied to *A. pubescens*, *A. glabra*, and *A. ruizii*. It differs from *A. pubescens* by having glabrous leaves and racemose (not glomerulate) inflorescences, and from both *A. glabra* and *A. ruizii* by having entire (not dentate) leaves and larger fruits. Vegetatively *A. macphersonii* resembles *A. longissima* but can be separated easily by the characters provided in the key. The occurrence of *A. macphersonii* in deciduous and semievergreen forests is unusual for the genus.

This species is named in honor of Dr. Gordon McPherson whose collecting efforts in Panama have yielded many new and interesting plants.

9. Ampelocera ruizii Klotzsch, Linnaea 20: 541. 1847. TYPE. Peru: *Ruiz & Pavón s.n.* (holotype, B).

Ampelocera verrucosa Kuhlm., Arch. Jard. Bot. Rio de Janeiro 4: 352. 1925. TYPE. Brazil. Pará: Itaituba, Rio Tapajoz, 20 Oct. 1922, *Ducke 19135* (holotype, B; isotypes, K, US).

Plagioceltis dichotoma Mildbr. ex Baehni, Contrib. Field Mus. Nat. Hist., Bot. Ser. 13: 272. 1937. TYPE. Peru: *Ruiz & Pavón s.n.* (holotype, MA, n.v.; isotype, F).

Trees 10–35 m tall; trunk up to 2.5 m dbh, with brown, flaky bark, and medium-sized buttresses; younger stems brown, glabrous to sparsely puberulent; older stems gray, glabrous; stipules 3–5 mm long, lanceolate, sparsely puberulent to pilose. Leaf blades elliptic to obovate, 6.5–13 × 2.5–6.5 cm, the acuminate tips 0.5–1 cm long and 2–3 mm broad, attenuate to rounded at the base, often oblique, drying stiffly chartaceous to subcoriaceous, glabrous and smooth above and beneath, with 3–5 teeth per side, occasionally entire; lateral veins 5–8, arcuate, raised beneath, puberulent beneath when young, becoming glabrous with age; petioles 0.5–1 cm long, sparsely puberulent, drying dark brown. Inflorescences of axillary, compound dichasia, on leafless branches, apparently with bisexual and staminate flowers (staminate flowers not seen); rachises 0.9–1.5 cm long, sparsely puberulent, with 8–15(–23) flowers. Flowers subtended by ovate bracteoles, these 1.5–2 mm long, glabrous to sparsely puberulent; calyx 2–2.5 mm long, the lobes 4, united at the base, sparsely villous; stamens 16 in perfect flowers; filaments ca. 3 mm long, linear, slender throughout; anthers ca. 1 mm long, the connective extended into an apicule ca. 0.5 mm long; ovary very densely pilose, with style branches 3–5 mm long, united in lower 1 mm. Fruits yellow, asymmetrical, transversely ellipsoid, 1–1.2 cm tall, 1.2–1.6 cm broad, slightly flattened, densely pilose, with persistent style branches; endocarp thin, ca. 0.3 mm thick.

Distribution, habitat, and phenology. This species is known from 0–500 m in lowland rainforest in Brazil, Peru, and Bolivia (Fig. 3). Flowering time is not known; fruiting is reported from August to January.

Steinbach 1309* (GH, NY, MO).

Ampelocera ruizii is distinguished from *A. glabra* by having smaller fruits and longer inflorescences. They are similar in having dentate, glabrous leaves and transversely ellipsoid, asymmetrical fruits.

Baehni (1937) separated *Ampelocera* from *Plagioceltis* and the other Peruvian genera of the Ulmaceae on the basis of the former having twice as many stamens as the latter. The isotype of *Plagioceltis dichotoma* at F, however, has a greater number of stamens than perianth parts. Since stamen number is not mentioned in the *Plagioceltis* description, Baehni's misplacement of the genus in the *Flora of Peru* key alongside genera possessing equal numbers of stamens and perianth segments is probably due to Mildbraed's inadequate notes (Gentry, 1983). As mentioned under taxonomic history, the similarity of the unnumbered Ruiz & Pavón type specimen of *Plagioceltis dichotoma* and the type of *Ampelocera ruizii* is the most likely because both originated from the same collection.

EXCLUDED TAXA

Ampelocera crenulata Urban, Repert. Spec. Nov. Regni Veg. 15: 399. 1919. TYPE. Cuba: *Ra-*

mon de la Sagra 413 (B, n.v.). = *Casearia praecox* Griseb. (Flacourtiaceae).

Ampelocera hondurensis J. D. Smith, Bot. Gaz. (Crawfordsville) 54: 244. 1912. TYPE. Honduras: Dept. Santa Bárbara, San Pedro Sula, 200 m, May 1890, *Thieme 5606* (US—3 sheets). = *Achatocarpus nigricans* Triana (Achatocarpaceae).

POLLEN MORPHOLOGY OF THE SHRUBBY IRIDACEAE *NIVENIA, KLATTIA,* AND *WITSENIA*[1]

Peter Goldblatt[2] *and*
John C. Manning[3]

ABSTRACT

Nivenia, Klattia, and *Witsenia,* a monophyletic assemblage of 13 species of the southwestern Cape, South Africa, have pollen grains with sculpturing similar to the basic type for Iridaceae (and for the monocots). The nearly spherical grains have a broad sulcus and reticulate to microreticulate exine. The supratectal gemmae, found only in *Witsenia,* are unique in Iridaceae. In *Nivenia* species the walls of the reticulum are lightly sculptured, sometimes laterally verrucate or micropapillate, the degree of sulpturing varying with the species. The pollen grains differ in size for all the species examined, and in four of the five heterostylous species of *Nivenia* there are statistically significant size differences between the long- and short-styled morphs.

The genera *Nivenia* (nine species), *Klattia* (three species), and *Witsenia* (one species) comprise a natural alliance of Iridaceae, restricted in distribution to the southwestern Cape region of southern Africa. Uniting the genera are the following specialized characters: a shrubby evergreen habit; a woody rootstock and aerial stems both having appreciable secondary growth; nonfugacious flowers with a well-developed perianth tube and bearing septal nectaries; tangentially compressed seeds; and a specialized leaf anatomy with submarginal sclerenchyma and girders produced by the extension to the epidermis of the sclerenchyma surrounding some of the vascular bundles (Goldblatt, in prep.; Goldblatt & Bernhardt, in press; Manning & Goldblatt, in prep.; Rudall & Burns, 1989).

This study of the pollen morphology of the three genera was undertaken in conjunction with a broadly based investigation of their systematics and reproductive biology, the latter focusing particularly on the heterostylous condition in five species of *Nivenia.* These distylous species are made up of populations of plants with either long styles and short stamens or short styles and long stamens. In many plants heterostyly is often associated with pollen dimorphism (Ganders, 1979; Richards, 1986) and this phenomenon has been considered in our examination of exine structure. The homostylous *Klattia* and *Witsenia* were included in our study for the sake of completeness. *Klattia* and *Witsenia* are probably bird pollinated (Rebelo, 1988; Goldblatt, in prep.) in contrast to species of *Nivenia* which are pollinated by long-tongued insects, either anthophorid bees or nemastrinid flies (Goldblatt & Bernhardt, in press). Any differences in the pollen of the three genera may be significant in light of the differences in their pollination biology.

MATERIALS AND METHODS

Pollen taken from herbarium specimens of 11 species (Table 1) was treated in one of two ways. For examination of exine sculpturing alone, untreated grains were glued on aluminum stubs and sputter coated with gold. For examination of whole grains, unacetolyzed pollen was rehydrated by warming in 10% KOH for ca. 10 minutes, then dehydrated in ethanol, rinsed twice in 50% acetone

[1] Support for this study by grant BSR 85-00148 from the U.S. National Science Foundation is gratefully acknowledged. We thank Sylvia Feuer, De Paul University, for her extensive help with the electron microscopy and for her comments on the manuscript, and Mike Veith, Washington University EM Unit, for his assistance with scanning electron microscopy. We also acknowledge the cooperation of the South African Department of Environment Affairs and the Cape Department of Nature and Environmental Conservation in providing collecting permits and access to field sites where the species used in this study were collected.

(listed in Table 3), where nine or ten grains in three or four individuals per style morph were measured (Table 3).

OBSERVATIONS

Grains of all species of all three genera are more or less spherical (Figs. 1–6), ranging from near prolate to near oblate depending on the species (Table 2). The monosulcate grains have a prominent elliptic to oblong sulcus (Figs. 2, 5, 6); they are tectate-perforate in *Witsenia* with a microreticulate tectum (Figs. 4–6, 9, 10) and semitectate with a reticulate tectum in *Nivenia* and *Klattia* (Figs. 1–3, 7, 8). The floors of the lumina in all the species are granulate (e.g., Fig. 7). The muri are smooth in *Klattia* (Fig. 8) but minutely granulate in *Nivenia* and *Witsenia* (e.g., Figs. 7, 9, 10). In *N. binata* and *N. stenisiphon* the sides of the muri are irregularly ridged (e.g., Fig. 7) (Table 2).

In *Nivenia* the luminae range from about as wide as the muri (microreticulate), e.g., *N. concinna* (Fig. 12), to about twice as wide (reticulate), or up to four times as wide in *N. capitata* (Fig. 11).

Supratectal gemmae (ca. 4 μm in diameter) are restricted to *Witsenia* (Figs. 5, 6) and are scattered more or less evenly across the surface.

The exine sculpturing ends abruptly at the sulcus (Fig. 2) in *Nivenia* and *Klattia*, but in *Witsenia* the muri become disrupted into pilae and baculae (Fig. 10) along the sulcus margins.

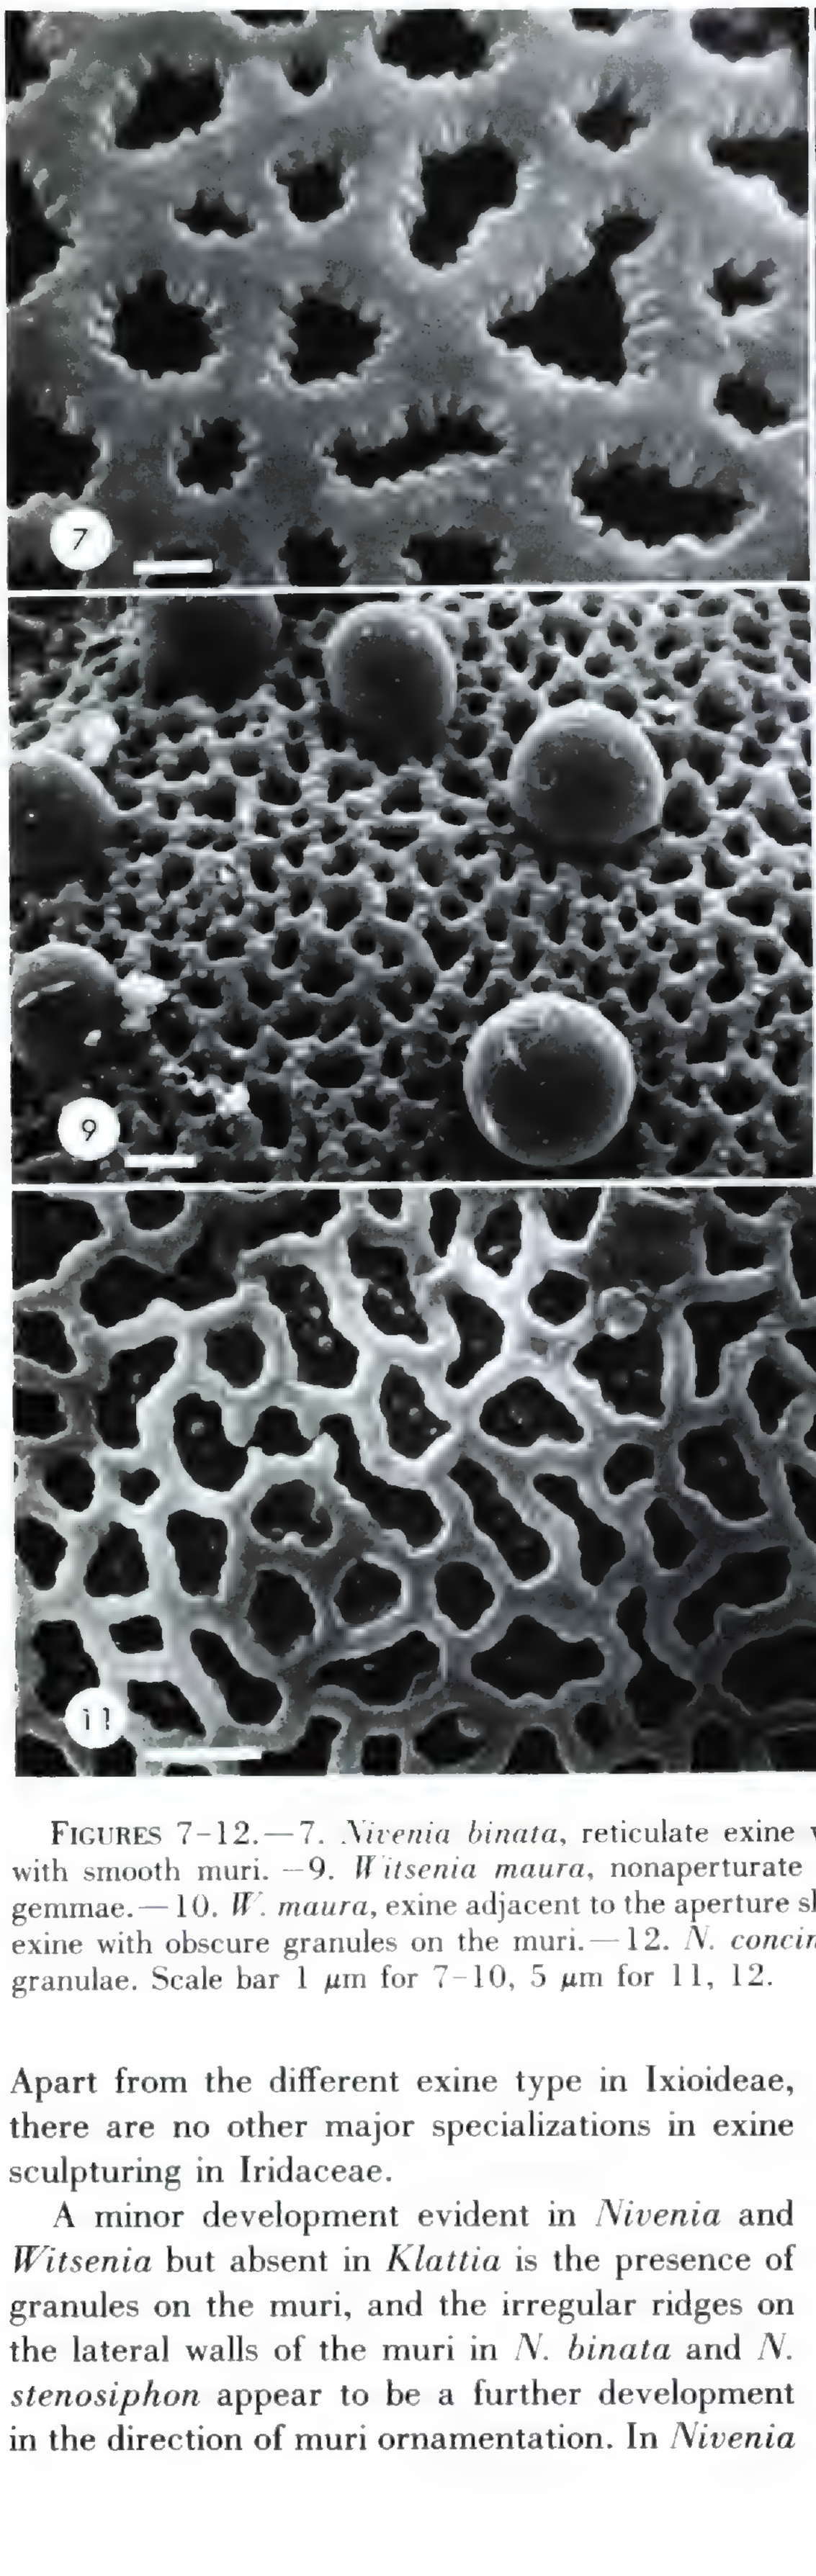
Pollen grain diameter ranges from 44.69 μm in the long-styled morph of *Nivenia corymbosa* to over 80 μm in *Klattia stokoei* and *Witsenia maura* (Table 2). Differences in pollen grain size among the species correlate generally with differences in style length. *Klattia* and *Witsenia* have the longest styles and largest pollen in the group, and *K. stokoei* the longest styles in that genus. *Nivenia levynsiae* and *N. concinna*, however, do not follow this trend, having shorter styles than one would expect from their comparatively large pollen grains.

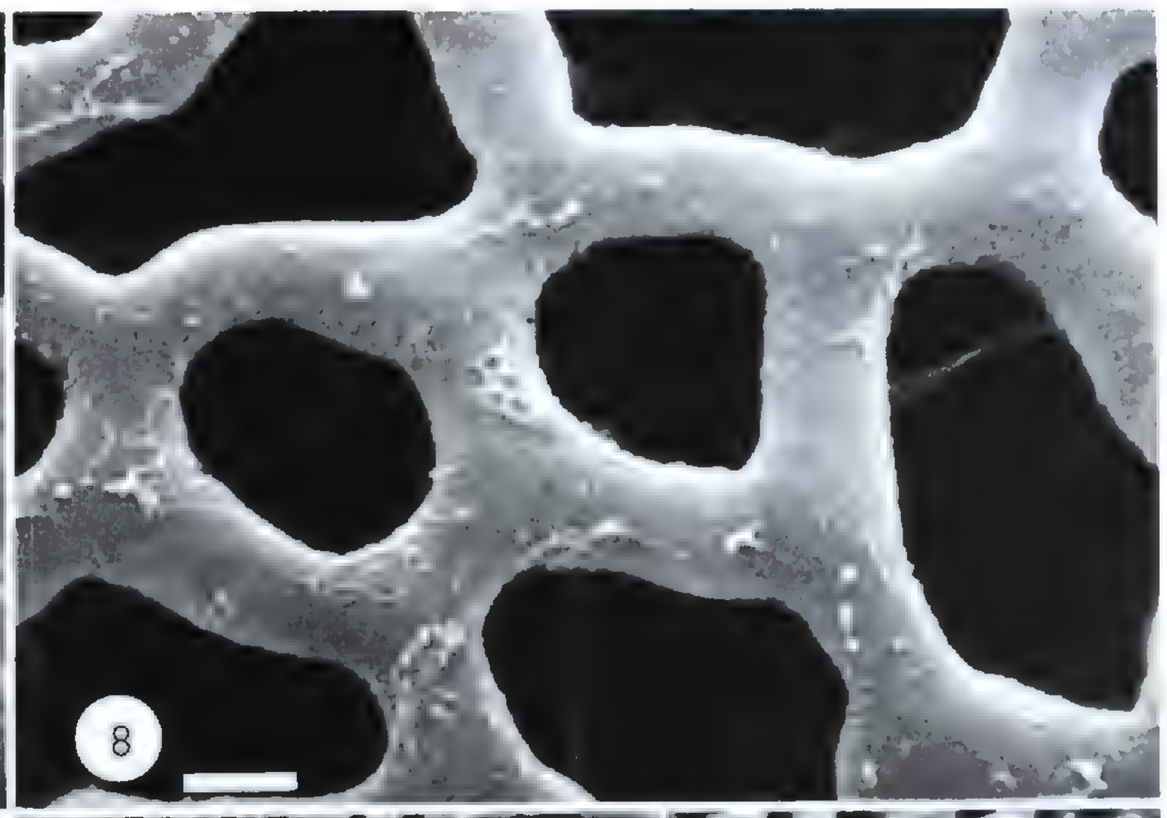
In four of the five heterostylous species of *Nivenia* the grains of the long-styled morph are significantly smaller (Table 3). Pollen size differences between morphs of the four heterostylous species also correlate directly with differences in style length in the complementary morph (Goldblatt & Bernhardt, in press). Exine sculpturing does not differ between morphs within the heterostylous species, but there are notable differences between the species. *Nivenia binata* exhibits the greatest degree of sculpturing and *N. capitata* the least (Figs. 7, 11).

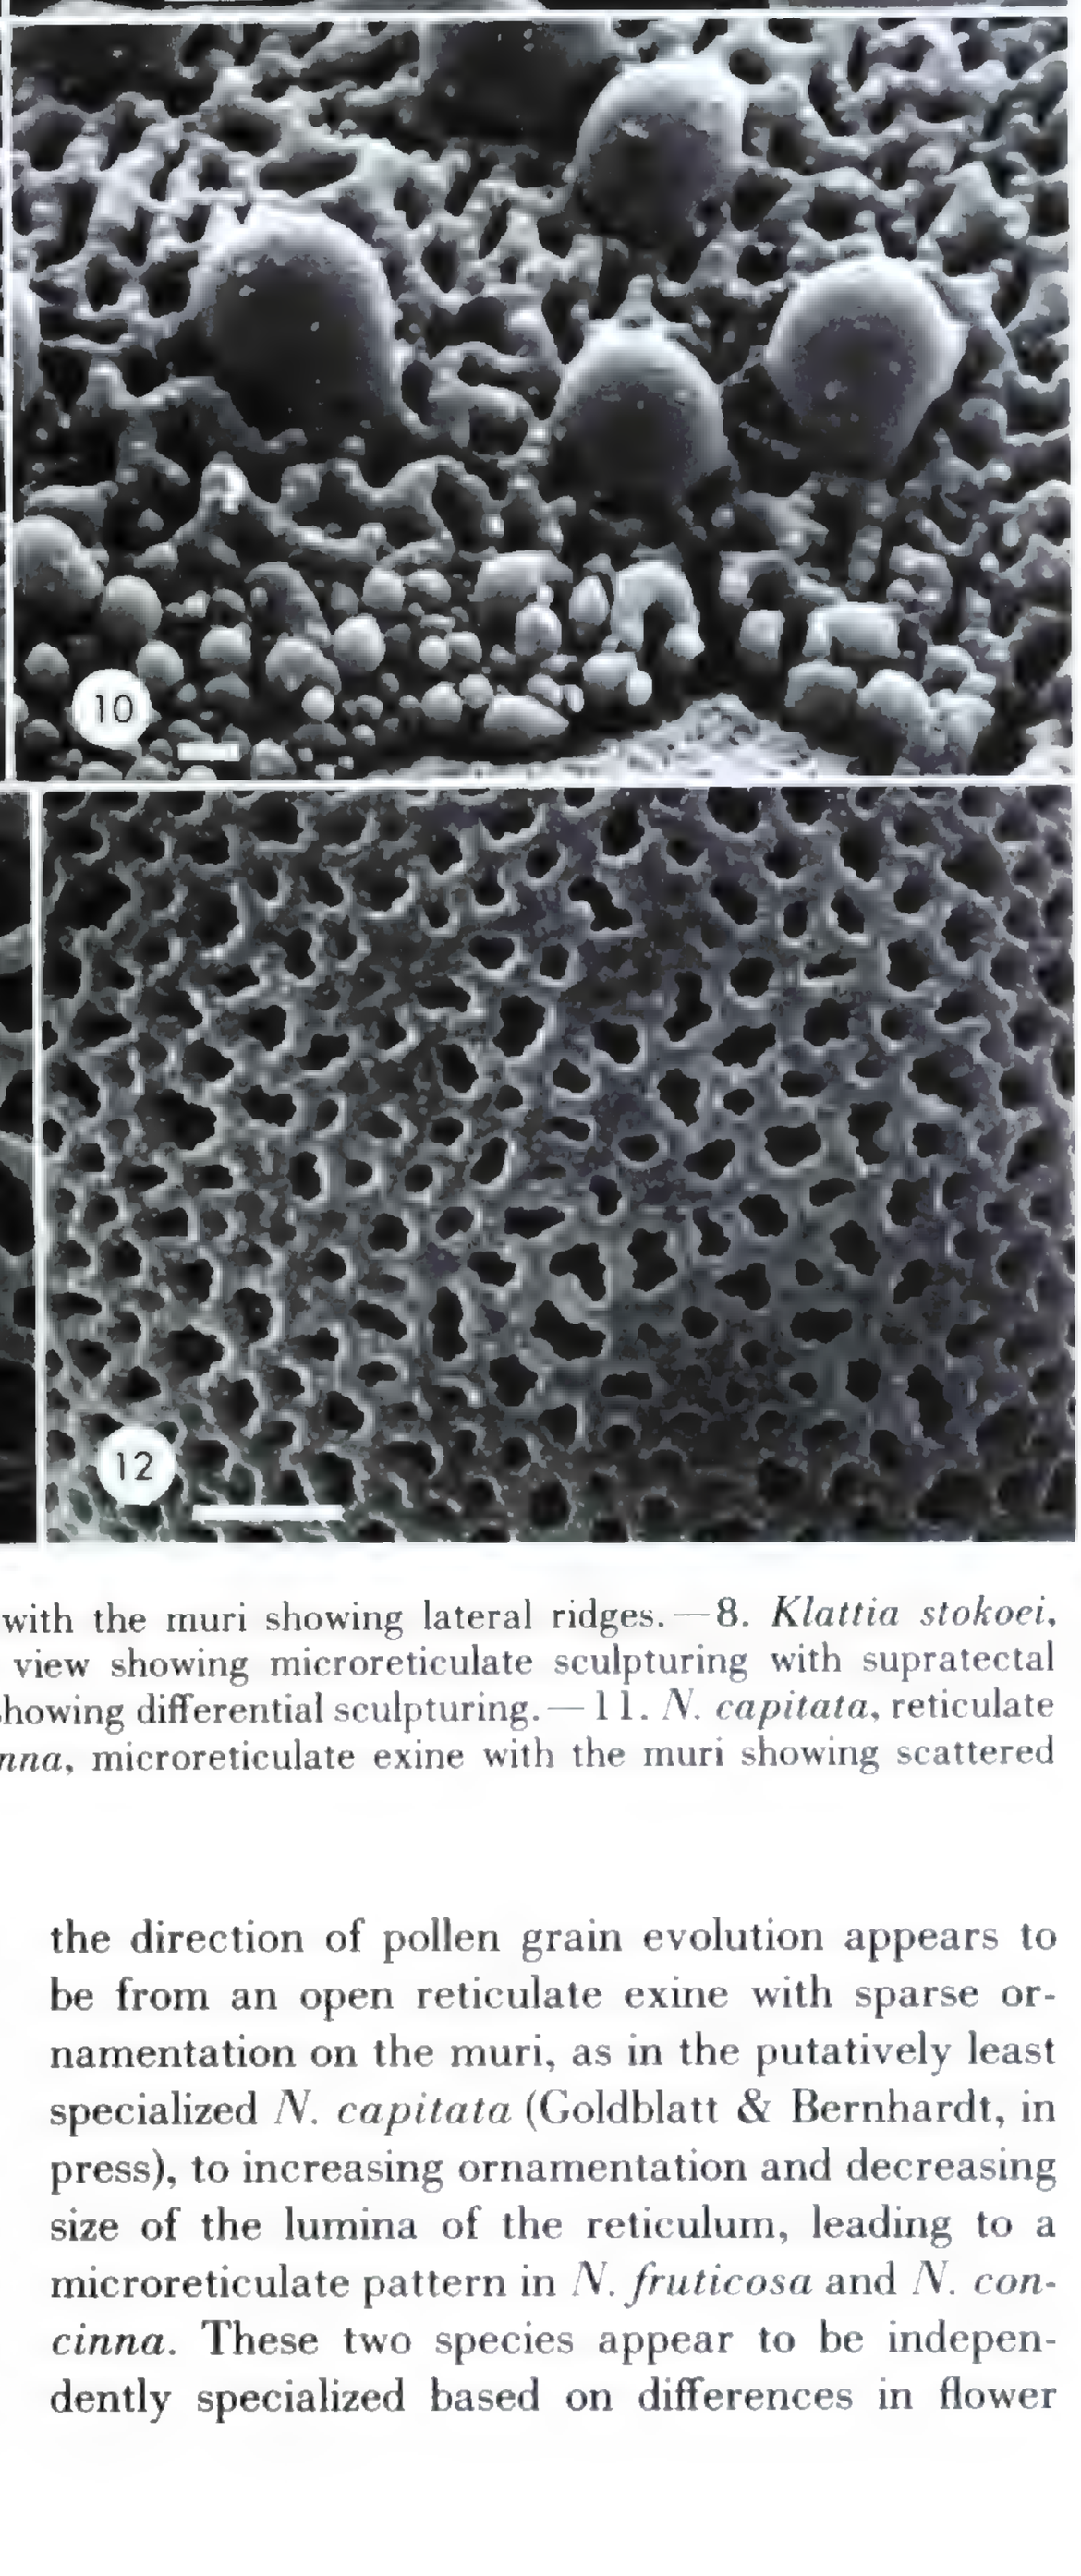
DISCUSSION

The pollen grains of *Nivenia* and *Klattia* conform fairly closely to the presumed basic type for Iridaceae and for the monocots in general, in which reticulate grains appear to be fundamental (Schulze, 1971; J. Walker, pers. comm.). Similar grains are found in species of *Aristea* (likewise Nivenioideae) and in numerous genera of Iridoideae, excluding *Iris*, in which there are multiple unusual specializations, particularly in the form of the aperture (Schulze, 1971). A group of New World genera of Iridoideae belonging to the tribe Tigridieae stand out in having bisulcate grains (Schulze, 1971), clearly a secondary condition in the tribe. Members of subfamily Ixioideae also differ markedly from this basic pollen type, having a tectate-microperforate exine with supratectal spinules (Erdtman, 1952; Schulze, 1971; Goldblatt & Stein, 1988).

Oblique apertural view showing differential sculpturing around the aperture. Scale bar 10 μm.







FIGURES 7–12.—7. *Nivenia binata*, reticulate exine with the muri showing lateral ridges.—8. *Klattia stokoei*, with smooth muri. —9. *Witsenia maura*, nonaperturate view showing microreticulate sculpturing with supratectal gemmae.—10. *W. maura*, exine adjacent to the aperture showing differential sculpturing.—11. *N. capitata*, reticulate exine with obscure granules on the muri.—12. *N. concinna*, microreticulate exine with the muri showing scattered granulae. Scale bar 1 μm for 7–10, 5 μm for 11, 12.

Apart from the different exine type in Ixioideae, there are no other major specializations in exine sculpturing in Iridaceae.

A minor development evident in *Nivenia* and *Witsenia* but absent in *Klattia* is the presence of granules on the muri, and the irregular ridges on the lateral walls of the muri in *N. binata* and *N. stenosiphon* appear to be a further development in the direction of muri ornamentation. In *Nivenia* the direction of pollen grain evolution appears to be from an open reticulate exine with sparse ornamentation on the muri, as in the putatively least specialized *N. capitata* (Goldblatt & Bernhardt, in press), to increasing ornamentation and decreasing size of the lumina of the reticulum, leading to a microreticulate pattern in *N. fruticosa* and *N. concinna*. These two species appear to be independently specialized based on differences in flower

and inflorescence morphology (Goldblatt, in prep.), and their similar pollen sculpturing is presumably convergent. The occurrence of ridged muri in *N. binata* and *N. stenosiphon*, however, appears to be an indication of close taxonomic relationship as it is correlated with two specialized characters restricted to these species: blue anthers and pollen, and large, dry, brown, crisped bracts (Goldblatt, in prep.).

The grains of *Witsenia*, with their large supratectal gemmae, are clearly derived. These distinctive gemmae, observed by Schulze (1971) under light microscopy, are unique in Iridaceae and make the pollen grains of this genus immediately recognizable. The presence of an unusual exine in *Witsenia* emphasizes the taxonomic isolation of this genus, distinctive in its unusual floral and inflorescence morphology. Any significance in the elaborate exine sculpturing of *Witsenia* in relation to its mode of pollination remains to be demonstrated.

Pollen sculpturing does not provide any character uniting the three shrubby genera of Cape Iridaceae, but within the alliance trends of specialization are evident in *Nivenia*, and the supratectal gemmae in *Witsenia* constitute an autapomorphy for this genus.

Mulcahy's (1965) report of a difference in size between the grains of the short- and long-styled morphs of *N. binata* is substantiated by our observations, although we noted a smaller size difference (ratio of grain size between short- vs. long-styled morph 1.11 compared with 1.3 reported by Mulcahy). We were unable to confirm Mulcahy's observation of differences in the size of the lumina of the exine reticulum between short- and long-styled grains in *N. binata*, nor did we record measurable differences in lumina size in the other heterostylous species.

The close similarity of the exine sculpturing and small, though statistically significant, differences in pollen grain size between the two style morphs in four of the observed heterostylous species of *Nivenia* are consistent with similar observations in many heterostylous taxa (Ganders, 1979; Richards, 1986). In *Nivenia* the morphological differences between the style morphs of the heterostylous species appear not to be accompanied by the expected self-incompatibility characteristic of most heterostylous plants (Goldblatt & Bernhardt, in press).

SEED MORPHOLOGY OF *SISYRINCHIUM* (IRIDACEAE—SISYRINCHIEAE) AND ITS ALLIES[1]

Peter Goldblatt,[2] James E. Henrich,[3] and Richard C. Keating[4]

ABSTRACT

Seeds of 25 species of sects. *Sisyrinchium*, *Echthronema*, *Eriphilema*, and *Nuno* of the large North and South American genus *Sisyrinchium* were examined using the scanning electron microscope and light microscope and compared with seeds of representative species of related genera in tribe Sisyrinchieae. Seeds of sects. *Sisyrinchium* and *Echthronema* are more or less rounded, are blackish with reticulate surfaces, and often have a large depression, the umbilicus, along the raphe. Species of sects. *Eriphilema* and *Nuno* have brown, more or less angular seeds with a strongly reticulate surface, and they lack an umbilicus. The genera *Libertia*, *Ona*, *Orthrosanthus*, *Phaiophleps*, *Solenomelus*, and *Tapeinia* have similar brown, usually angular seeds without an umbilicus. Seeds of *Solenomelus* have distinctive longitudinal lines of nearly circular depressions along the seed body, and one species has seeds with a large, half-circumferential wing. Seeds of sects. *Sisyrinchium* and *Echthronema* appear to embody important, probably derived specializations. Based on seed characters, sects. *Eriphilema* and *Nuno* seem more closely related to the other genera of Sisyrinchieae, particularly *Phaiophleps*, than to sects. *Sisyrinchium* or *Echthronema*.

In the course of a systematic study of the New World genus *Sisyrinchium* for *Flora Mesoamericana* (Henrich & Goldblatt, 1987, in press a) and *Flora de Nicaragua* (Henrich & Goldblatt, in press b) our attention was drawn to the unusual rounded, blackish, umbilicoid seeds of the genus. The seeds were novel to us in Iridaceae and distinguish *Sisyrinchium* from all other genera in the family. Seed characters were also useful in establishing species limits within the genus. We found no adequate description or record of *Sisyrinchium* seeds in the literature, and Huber (1969) did not specifically describe them in his extensive study of the seeds of lilioid monocots. However, Cholewa & Henderson (1984) included SEM examination of six North American species of sect. *Sisyrinchium*, and Rodriguez (1986) mentioned color and surface texture in his revision of the Chilean species of *Sisyrinchium*.

With this background we undertook the present survey of the seeds of *Sisyrinchium* and its allies in tribe Sisyrinchieae of subfamily Iridoideae (classification after Goldblatt, 1990). *Sisyrinchium* as presently constituted (Bentham & Hooker, 1883; Baker, 1892) comprises over 100 species. Our study includes a small but representative sample of the total and is sufficient to satisfy our purpose in documenting the basic seed types found in the genus and to allow a valid comparison with allied genera. We included taxa from the two large and apparently natural sects. *Sisyrinchium* (= sect. *Bermudiana* of several authors) and *Echthronema* (Bentham & Hooker, 1883) and the smaller sects. *Eriphilema* and *Nuno*. Related genera of tribe Sisyrinchieae (sensu Goldblatt, 1990) examined for comparison were *Libertia*, *Ona*, *Orthrosanthus*, *Phaiophleps*, *Solenomelus*, and *Tapeinia*. Seeds of *Chamelum*, which belongs in this alliance, were not available. The southern African *Bobartia* and the Australian *Diplarrhena*, the remaining genera of the tribe, appear to be more distantly related to the *Sisyrinchium* complex and neither was included in our survey. Sections *Eriphilema* and *Nuno* and the other genera examined have seeds

ANN. MISSOURI BOT. GARD. 76: 1109–1117. 1989.

fairly typical of Iridaceae in their brownish color and more or less angular shapes (Huber, 1969) and are very different from the seeds found in sects. *Sisyrinchium* and *Echthronema*.

Materials and Methods

Mature seeds were assembled from herbarium material, and in a few cases fresh field-collected seeds were examined (Table 1). We excluded seeds that appeared deformed or showed signs of fungal infection. Seeds were examined under the light microscope for size and color, and then prepared for the scanning electron microscope (SEM) study by attachment with water-soluble white glue to aluminum stubs and sputter coating with 500–700 Å of gold. They were examined in an ISI Super IIIA SEM at 15 kV.

Observations

color

Seeds of all the species of *Sisyrinchium* sects. *Sisyrinchium* and *Echthronema* are blackish (Table 2). Surface color intensity ranges from a fairly glossy, intense black to matte and dark gray. As we used seeds almost exclusively from herbarium specimens, we are uncertain how much significance to attribute to the color variation as ripening may have been affected by the rapid drying, and the final seed appearance may thus not be the same as in nature.

Seeds of *Sisyrinchium* sects. *Eriphilema* and *Nuno* and of the genera *Libertia*, *Ona*, *Orthrosanthus*, *Phaiophleps*, *Solenomelus*, and *Tapeinia* are shades of brown (Table 2), most often red-brown, presumably the basic condition in the family (Huber, 1969) and an indication of the presence of the pigment phlobaphene. Some species, for example *Orthrosanthus occissapungus*, have light brown seeds, an apparently significant character at the species level.

shape and size

The number of seeds per locule of the three-chambered capsules of Sisyrinchieae was not recorded in our study, but all species examined have multiseeded loculi. The effect of crowding and alteration of shape by mutual pressure within the locules (Huber, 1969; Wagner & Goldblatt, 1984) was noted to some degree in most species. Angular seeds characterize *Libertia* and *Orthrosanthus* (Figs. 1–3). *Phaiophleps* and *Sisyrinchium* sect. *Eriphilema* have less sharply angular seeds (not illustrated), sometimes tending toward rather obtusely angled and differing consistently in basic shape from the rounded seeds of sects. *Sisyrinchium* and *Echthronema*. Seeds of two species of *Solenomelus* are cylindric to barrel-shaped with distorted angular ends (e.g., *S. segethii*, Fig. 5). In a third, possibly new, species of *Solenomelus* (Fig. 6) the seeds have a broad, membranous, half-circumferential wing. The seeds of *Orthrosanthus occissapungus* (Fig. 3) have the proximal and distal ends produced into winglike processes, but other species of the genus have angular seeds, as illustrated by Takhtajan (1985) for *O. chimboracensis*. In *Tapeinia* (Fig. 4) the seeds are nearly pyriform to elongate-pyriform, narrowest at the chalazal end. The raphe is usually distinct and terminates in a small depression in which we assume the micropyle is located. The least effect of crowding was found in sects. *Sisyrinchium* and *Echthronema*. There, except for the small persistent funicle, the seeds (Figs. 7–18) are nearly regularly spherical to rounded or sometimes somewhat depressed (e.g., *S. chiricanum*, Fig. 16).

Seed size varies considerably (Table 2) within genera. Thus in *Sisyrinchium*, *S. minus* has seeds 0.6 × 0.4 mm, whereas those of *S. chiricanum* are ca. 2.5 mm in diameter. The seeds of *Solenomelus* are even larger, with a maximum length of 5.5 mm attained by *Solenomelus* sp.

There is a regular pattern of small, evenly spaced, irregularly rounded depressions oriented in lines running along the long axis of the seeds of all three species of *Solenomelus* (Figs. 5, 6). In *Solenomelus* sp. these depressions are limited to the area covering the seed body.

A conspicuous, often large pit, which we here call an umbilicus, is an outstanding feature of the seeds of most species of sects. *Sisyrinchium* (Figs. 9, 10) and *Echthronema* (Figs. 13–18) (Table 2). The umbilicus straddles the raphe, either between the hilum and the micropyle (Figs. 17, 18), or the umbilicus includes the micropyle (Figs. 13, 15).

surface morphology and microsculpturing

Outlines of the testa cells often form a pronounced reticulum owing to the typical condition in Iridaceae for the outer periclinal walls to collapse while the thickened anticlinal walls persist (e.g., Figs. 1–4). The seed surfaces thus have a reticulate appearance. In some species of sect. *Echthronema* the surfaces exhibit little texture and in *S. trinerve* (Fig. 15) are nearly smooth. We did not find examples of the somewhat irregularly granular surfaces and diffuse reticulation without cell outlines

for *Sisyrinchium montanum*, and *S. pallidum*, and by Rodriguez (1986) for the Chilean *S. azureum*, all sect. *Sisyrinchium*. Among the species that we examined, this was noted particularly in *S. chiricanum*, *S. convolutum*, *S. commutatum* (Fig. 19), and *S. tinctorium* (all sect. *Echthronema*). Even the apparently smooth seed surface of *S. trinerve* shows this granularity at very high magnification.

very high magnification. No granular microsculpturing was noted in species of any other genus included in our survey.

In *Solenomelus* the longitudinal lines of more or less circular depressions do not correspond to the surface cells. The depressions are larger than the individual cells, the outlines of which can be clearly seen over the entire seed surface in *S. segethii* (Fig. 5), but are rather obscure in *Solenomelus* sp. (Fig. 6) and *S. pedunculatus*. In the latter the peripheral cells of the seed are unusual in being elongate and they have a remarkably smooth surface (Fig. 20).

DISCUSSION

Most Iridaceae have seeds of a light to middle brown, sometimes reddish brown (Huber, 1969; Wagner & Goldblatt, 1984), the coloration attributed to the presence of phlobaphene (Huber, 1969). A few exceptions include the glossy black seeds of *Belamcanda* (tribe Iridoideae) and *Babiana* and *Antholyza* (tribe Ixioideae), and the bright orange seeds of *Chasmanthe* (also Ixioideae) and *Neomarica variegata* (Iridoideae tribe Mariceae). Whether the black color in the above genera or in *Sisyrinchium* can be attributed to the presence of phytomelan, a dense carbon substance that is regarded as important in the higher systematics of the lilioid monocots (Dahlgren & Rasmussen, 1983; Dahlgren et al., 1985), is unknown.

The most common seed shape in Iridaceae is more or less regularly angular (Huber, 1969) but globose or subglobose seeds are not uncommon. Winged seeds occur in *Gladiolus* and its close allies (Ixioideae), and discoid seeds are characteristic of some species of *Iris* and *Moraea* (both Iridoideae–Irideae) and *Diplarrhena* (Sisyrinchieae). The half-circumferentially winged seeds of *Solenomelus* sp. are reminiscent of those of *Gladiolus* (which have completely circumferential wings) and represent a notable example of convergence.

Until now the blackish seeds encountered in *Sisyrinchium* appear not to have been regarded as particularly significant, although the basic differences in seed color have been noted by Rodriguez (1986), black in species attributable to sects. *Sisyrinchium* and *Echthronema* and brownish in sect. *Eriphilema*. Moreover, the more or less globose shape and the frequent presence of a large umbilicus along the raphe, either between the hilum and micropyle or including the latter, appear to have attracted little attention except for occasional mention in species descriptions. We believe that these features have considerable taxonomic significance, particularly in a genus that is relatively unspecialized in the family and has few other distinguishing characteristics.

A conclusion that appears warranted is that the black, globose, and umbilicoid seeds are a derived (apomorphic) condition in sects. *Sisyrinchium* and *Echthronema*. It is likely, though by no means certain, that this seed, including the umbilicus, is the basic type in the two sections despite the fact that an umbilicus is not present in a few North and South American species of both sections.

Seed data indicate that sects. *Sisyrinchium* and *Echthronema* should be considered sister taxa more closely allied to each other than to sects. *Eriphilema* and *Nuno*. The possibility that sects. *Eriphilema* and *Nuno* may be more closely allied to other genera of Sisyrinchieae, *Phaiophleps* in par-

ticular, than to the rest of *Sisyrinchium* will be explored in a future paper dealing with the phylogeny of Sisyrinchieae.

NEW SPECIES OF *MENDONCIA* (ACANTHACEAE) FROM THE VENEZUELAN GUAYANA[1]

Dieter C. Wasshausen[2]

ABSTRACT

Recent expeditions in the Venezuelan Guayana have resulted in additional new taxa in the genus *Mendoncia* (Acanthaceae). The following is an effort to place these novelties on record for the convenience of other taxonomists prior to the publication of the *Flora of the Venezuelan Guayana*. Four new Venezuelan Guayana species of *Mendoncia*, *M. steyermarkii*, *M. neblinensis*, *M. williamsii*, and *M. coriacea*, are described, illustrated, and compared with their closest relatives.

There are approximately 60 species of *Mendoncia* in Central and South America and in tropical Africa and Madagascar. The genus, named for Cardinal Mendonça, Patriarch of Lisbon, consists of twining herbaceous or sometimes suffrutescent climbers bearing cylindric red, white, or cream-colored axillary flowers with purple streaks in the throat. Each flower is subtended by a pair of conspicuous, green, more or less connate bracts. Most taxa are limited to wet virgin forests and thickets at elevations between 50 and 1,000 m. Due to the fact that lianas and vines are generally poorly known and collected in the tropics, and given the superficial similarity of many of the species, the taxonomy of the genus is rather difficult. In an attempt to identify recent collections of *Mendoncia* from the Venezuelan Guayana, I have found four undescribed species of the genus.

KEY TO THE VENEZUELAN GUAYANA SPECIES OF *MENDONCIA*

1a. Bracts ovate or oblong-ovate.
  2a. Flowers 4 or 5 in each axil ..... *M. cardonae*
  2b. Flowers solitary or in pairs in each axil.
    3a. Corolla cream-colored with purple streaks in the throat; bracts 2 cm long and 1 cm broad ..... *M. sprucei*
    3b. Corolla bright to deep red; bracts 2.3–3 cm long, 1.3–1.7 cm broad.
      4a. Bracts yellowish green to brownish green, 2.5–3 cm long, hirsute; leaf blades membranous, dark green and lustrous above, glabrous; corolla 3.5 cm long ..... *M. neblinensis*
      4b. Bracts dull green, 2.3 2.5 cm long, densely hirsute; leaf blades firmly membranous, dull dark green above, sparingly hirsute; corolla 3 cm long ..... *M. steyermarkii*
1b. Bracts oblong, oblong-elliptic, or oblong-obovate.
  5a. Bracts narrowly oblong or oblong-lanceolate.
    6a. Leaf blades narrowly to broadly elliptic, rather thin, densely pubescent; bracts narrowly oblong, 3.5 cm long, 0.8 cm broad, densely velvety pubescent ..... *M. hoffmannseggiana*
    6b. Leaf blades elliptic, chartaceous, minutely and sparingly hirtellous; bracts oblong-lanceolate, 2 to 2.5 cm long, 1 cm broad, densely brown strigose ..... *M. williamsii*
  5b. Bracts oblong, oblong-elliptic or oblong-obovate.
    7a. Bracts oblong or oblong-elliptic, coriaceous; leaf blades subcoriaceous to thick-coriaceous.
      8a. Leaf blades elliptic to oblong, 3 6 cm broad; bracts vinaceous-lavender with green, oblong ..... *M. coriacea*
      8b. Leaf blades oblong-elliptic, 7.5 9 cm broad; bracts green, oblong-elliptic ..... *M. phalacra*
    7b. Bracts oblong-obovate to oblong-elliptic, not coriaceous; leaf blades membranous, not coriaceous.
      9a. Bracts oblong-obovate, 1–1.3 cm broad, essentially glabrous; stem glabrous; leaf blades glabrous, chartaceous, the veins prominent on the lower surface ..... *M. obovata*
      9b. Bracts oblong-elliptic, 1.5 1.8 cm broad, long-hirsute; stem hirsute; leaf blades hirsute, membranous, the veins inconspicuous on the lower surface ..... *M. bivalvis*

Mendoncia neblinensis Wasshausen, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: along Río Baria just upstream from Base Camp on SW side of Cerro de la Neblina, 0°49′50″N, 66°09′40″W, 140 m, 27 Jan. 1985, *M. Nee 30578* (holotype, US; isotype, NY). Figure 1A, B.

Frutex volubilis, caulibus subquadrangularibus, parce hirsutis et lepidotis, pilis ascendentibus. Foliorum lamina elliptica vel ovata, apice abrupte acuminata et aristata, basi abrupte acuta, supra atroviridis et subnitida, glabra vel parce puberula, subtus pallide viridis, glabra vel parce hirsuta, costa et venis lateralibus subtus prominentibus; petioli subquadrangulares, parce hirsuti; flores (1 vel 2) axillares; pedicelli tortiles, parce hirtelli, pilis appressis; bracteae ovatae, flavido- vel brunneolo-virides, apice apiculatae, extus hirsutae et minute muricatae, intus glabrae et minute rugosae; corolla vivido rubra vel atrosanguinea, glabra vel parce hirsuta versus faucem, lobis ellipticis vel obovatis, leviter emarginatis; drupa ellipsoidalis, glabra.

Climbing vine; stem subquadrangular, sparingly hirsute and lepidote with stellate scales, the trichomes ascending. Leaves petiolate, the petioles 1–2.5 cm long, subquadrangular, sparingly hirsute, the blades elliptic to ovate, thinly membranaceous, 5–11 cm long, 3–5.5 cm broad, abruptly acuminate, the tip aristate, the awn to 6 mm long, abruptly acute at the base, the upper surface dark green and lustrous, glabrous or bearing a few appressed trichomes arising from stellate bases, minutely punctate, the lower surface paler and dull green, glabrous or sparsely hirsute (especially the costa and lateral veins bearing a few appressed trichomes), the venation prominent beneath, lateral veins 3 or 4 pairs, veinlets coarsely reticulate. Flowers axillary, 1 or 2 in each axil, the pedicels 3.5–5.5 cm long, twisted, gradually enlarged towards tip, sparingly hirtellous, the trichomes appressed upward, straight; bracts ovate, yellowish green to brownish green, 2.5–3 cm long, 1.3–1.7 cm broad, apiculate, the apicula about 1 mm long, the outer surface minutely muricate and hirsute, the trichomes straight, rigid, appressed upward, the costa rather prominent, the inner surface glabrous, minutely rugose; corolla bright to dark red, 3.5 cm long, the lobes pink within, base of tube white, glabrous or sparingly hirsute towards the throat, the tube 5 mm broad at base, narrowed to 2.5 mm at 8 mm above base, the throat 8 mm broad, the upper lip about 8 mm long, the lobes subequal, elliptic to obovate, 5 mm long and 3.5 mm broad, shallowly emarginate at apex, the lower lip somewhat shorter than the upper lip; pollen grains 5-colporate (brevissimicolpate), prolate-spheroidal, 34 × 30 μm, sexine punctitegillate; calyx annular, 0.5 mm long, glabrous; style 2.5 cm long, glabrous; ovary glabrous. Drupe fleshy, black, ellipsoid, 17 mm long, 8 mm wide, glabrous.

Distribution. Lowland evergreen tropical forest on hummocks along gravelly black-water rivers, Territorio Federal Amazonas at elevations between 100 and 180 m.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Cerro de la Neblina, along Río Mawarinuma, 0°50′N, 66°10′W, 140 m, *Stein, Gentry & Thomas 1716* (MO, US); same locality, *Davidse & Miller 27452* (MO, US); same locality, *Liesner 15667* (MO, US); same locality, *Liesner 17273* (MO, US); same locality, *Liesner & Funk, 15822* (MO, US); same locality, *Thomas 3318* (MO, US); same locality, *Kral 71816* (US); same locality, *Thomas 3374* (NY, US); upper Río Baria, ca. 0°55′N, 66°15′W, 100 m, *Davidse & Miller 26899* (MO, US); between base camp and "Puerto Chimo" along Río Mawarinuma, 0°50′N, ca. 66°8′W, 150 180 m, *Gentry & Stein 46967* (MO, US); 2 6 km E of base camp, 0°50′N, 66°08′W, 160 m, *Thomas 3196* (NY, US).

Mendoncia neblinensis is probably related to *M. sprucei* Lindau. It differs markedly from *M. sprucei* in that the latter species has green bracts 2 cm long and 1 cm broad, sparingly appressed-pilose pubescence on the leaf blades, and corollas 3 cm long. In contrast, *M. neblinensis* has yellowish to brownish green bracts 2.5–3 cm long and 1.3–1.7 cm broad, glabrous leaf blades, and corollas 3.5 cm long. Lindau (1897) in his description of *M. sprucei* did not indicate the color of the corolla, nor did Turrill (1919) in his revision of the genus. Leonard (1951) described the corolla of *M. sprucei* as cream colored with purple streaks in the throat. I believe this to be in error; the corolla of *M. sprucei* is also bright red. Turrill (1919) stated in his discussion that *M. sprucei* appears to be very closely related to the red-flowered *M. aspera* Nees and that perhaps *M. sprucei* was only a variety of *M. aspera*.

Mendoncia steyermarkii Wasshausen, sp. nov. TYPE: Venezuela. Estado Bolivar, en el drenaje del Río Cuyuní, al sur de El Dorado, 1,300–1,380 m, 22 28 Dec. 1979, *Julian A. Steyermark & G. C. K. & E. Dunsterville 104353* (holotype, US; isotype, VEN). Figure 1C–E.

Frutex volubilis, caulibus subquadrangularibus, sulcatis, parce lepidotis, parce hirsutis, pilis ascendentibus. Foliorum lamina ovata, abrupte acuminata apice aristata, base abrupte acuta vel obtusa, aliquanto membranacea, integra, supra atroviridis, parce hirsuta, subtus fulvo-viridis, glabra vel costa et venis lateralibus parce strigosis; petioli glabri vel in canalibus parce hirsuti; flores (1 vel 2) axillares; pedicelli recti, flavo-virentes, dense hirtelli; bracteae ovatae, obscure virides, apiculatae, externe dense hirsutae, minute muricatae, intus glabrae et minute ru-

gosae; corolla atrosanguinea, glabra, lobis rotundatis vel leviter emarginatis; drupa subglobosa, nitida, glabra.

Trailing vine; stems subquadrangular, grooved, sparingly lepidote (the scales stellate), bearing numerous ascending, erect, hirsute trichomes. Leaves on petioles 1–2.5 cm long, subquadrangular, glabrous or the channels sparingly hirsute with straight ascending trichomes, the blades firmly membranous, ovate, 9–11 cm long and 4–6.5 cm broad, apically abruptly acuminate (the tip aristate, the awn 6 mm long), the base abruptly acute to obtuse, the upper surface dull dark green, sparingly hirsute, the trichomes straight, ± ascending, arising from stellate bases, the lower surface dull tawny green, glabrous or the costa and lateral veins bearing a few scattered, stiff, straight, ascending trichomes, lateral veins 3 or 4 pairs, veinlets coarsely reticulate, the venation prominent and raised beneath, less so above. Flowers axillary, 1 to 2 in each axil, the pedicels yellow-green, 4–6 cm long, straight, densely hirtellous, the trichomes appressed upward, straight, rigid; bracts dull green ovate, 2.3–2.5 cm long, 1.3–1.5 cm broad, with an apicula about 1 mm long, the outer surface minutely muricate and densely hirsute with straight, rigid, trichomes, these appressed upward, the costa rather prominent, the inner surface glabrous, minutely rugose; corolla deep red, glabrous, 3 cm long, the tube 5.5 mm broad at base, narrowed to 3 mm at 5 mm above base, the throat 8 mm broad, the upper lip about 5 mm long, the lobes rounded, 3.5 mm broad, shallowly emarginate at apex, the lower lip somewhat shorter than the upper lip; pollen grains 5-colporate (brevissimicolpate), prolate-spheroidal, 42 × 37 μm, sexine punctitegillate; calyx annular, 0.5 mm long, glabrous; style 2.8 cm long, the lower portion hirsute; ovary glabrous. Drupe subglobose, black, shining, 15–18 mm diam., glabrous.

Distribution. Wooded ridge and tall, moist forests with trees on the average 25–30 m tall, Estado Bolívar, Venezuela, at 1,100–1,400 m.

Paratypes. VENEZUELA. BOLIVAR: Gran Sabana, El Dorado Sta. Elena de Uairen road, km 131, 1,200 1,400 m, *J. Steyermark, L. & R. Smith, G. C. K. & E. Dunsterville 105454* (US, VEN); El Dorado–Sta. Elena de Uairen road, km 127 131, 1,300–1,350 m, *Badillo & Holmquist 6094* (MY, US); El Dorado–Sta. Elena de Uairen road, km 119–122, S of El Dorado, ca. 1,100 m, *Gentry, G. Morillo & B. de Morillo 10460* (MO, US); carretera between campamento 125 and km 127, between Luepa and Cerro Venamo, 1,200 m, *Steyermark & Nilsson 194* (US, VEN); 134 km S of El Dorado, 1,300 1,350 m, *Steyermark & G. C. K. & E. Dunsterville 104450* (US); carretera El Dorado–Gran Sabana, La Dante, 1,250 m, *Ruiz-Terán & López-Palacios 11460* (MERF, US).

Mendoncia steyermarkii superficially resembles the Colombian lowland forest species *M. caquetensis* Leonard. However, in *M. caquetensis* the bracts are green and sparingly and inconspicuously hirsute; and the corollas are white(?) (*fide* Leonard, 1961) with the tube 4 mm broad at the base and narrowed to 2.5 mm at 1 cm above the base, and the upper lip is about 1 cm long. In *M. steyermarkii*, the bracts are dull green and densely hirsute, the corollas are deep red with the tube 5.5 mm broad at the base and narrowed to 3 mm at 0.5 cm above the base, and the upper lip is about 0.5 cm long.

Mendoncia williamsii Wasshausen, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: forest at Capihuara, Casiquiare, 120 m, 30 May 1942, *Llewelyn Williams 15697* (holotype, US; isotype, VEN). Figure 2A–C.

Frutex volubilis, caulibus subquadrangularibus, strigosis, pilis brunneis. Foliorum lamina elliptica, breve acuminata, cuspidata, basi acuta, chartacea, integra, supra (in sicco) subnigra, parce et minute hirtella, pilis a basibus planis stellatis orientibus, subtus (in sicco) brunnea, aequaliter strigosa; petioli strigosi; flores 2, axillares; pedicelli dense brunneo-strigosi; bracteae oblongo-ovatae, apice acutae, extus dense brunneo-strigosae, costa aperta; corolla non visa; drupa ovoidea, leviter compressa, minute pubescens.

Vine; stem subquadrangular, rather densely strigose upward, the trichomes brownish, to 2.5 mm long. Leaves on petioles 1–2 cm long, strigose, the blades elliptic, to 15 cm long and 9 cm broad, apically short-acuminate with a cusp to 5 mm long, basally acute, chartaceous, entire, the upper surface drying blackish, minutely and sparingly hirtellous with the ascending hairs 0.25–0.50 mm long and arising from flat, stellate bases, the costa and lateral veins (4 or 5 pairs) rather prominent, strigose with brown trichomes about 1 mm long, the lower surface drying brown, ± evenly strigose, both surfaces bearing rather prominent coarsely reticulate veinlets. Flowers usually 2 in each axil; pedicels 4 cm long, densely brown strigose; bracts oblong-lanceolate, 2–2.5 cm long, 1 cm broad just above base, gradually narrowed to an acute tip, densely brown-strigose, the costa evident, the inner surface glabrous; flowers not seen. Drupes 1.5 cm long, 6 mm wide, 4 or 5 mm thick, oblique at tip, the surface minutely and rather densely pubescent.

Distribution. In dense forest of terra firma, Territorio Federal Amazonas, Venezuela. Known only from the type locality.

FIGURE 2. A–C. *Mendoncia williamsii* (*L. Williams 15697*).—A. Habit.—B. Bracts.—C. Drupe and bract. D–F. *Mendoncia coriacea* (*Steyermark & G. C. K. & E. Dunsterville 104474*).—D. Habit.—E. Bracts.—F. Corolla.

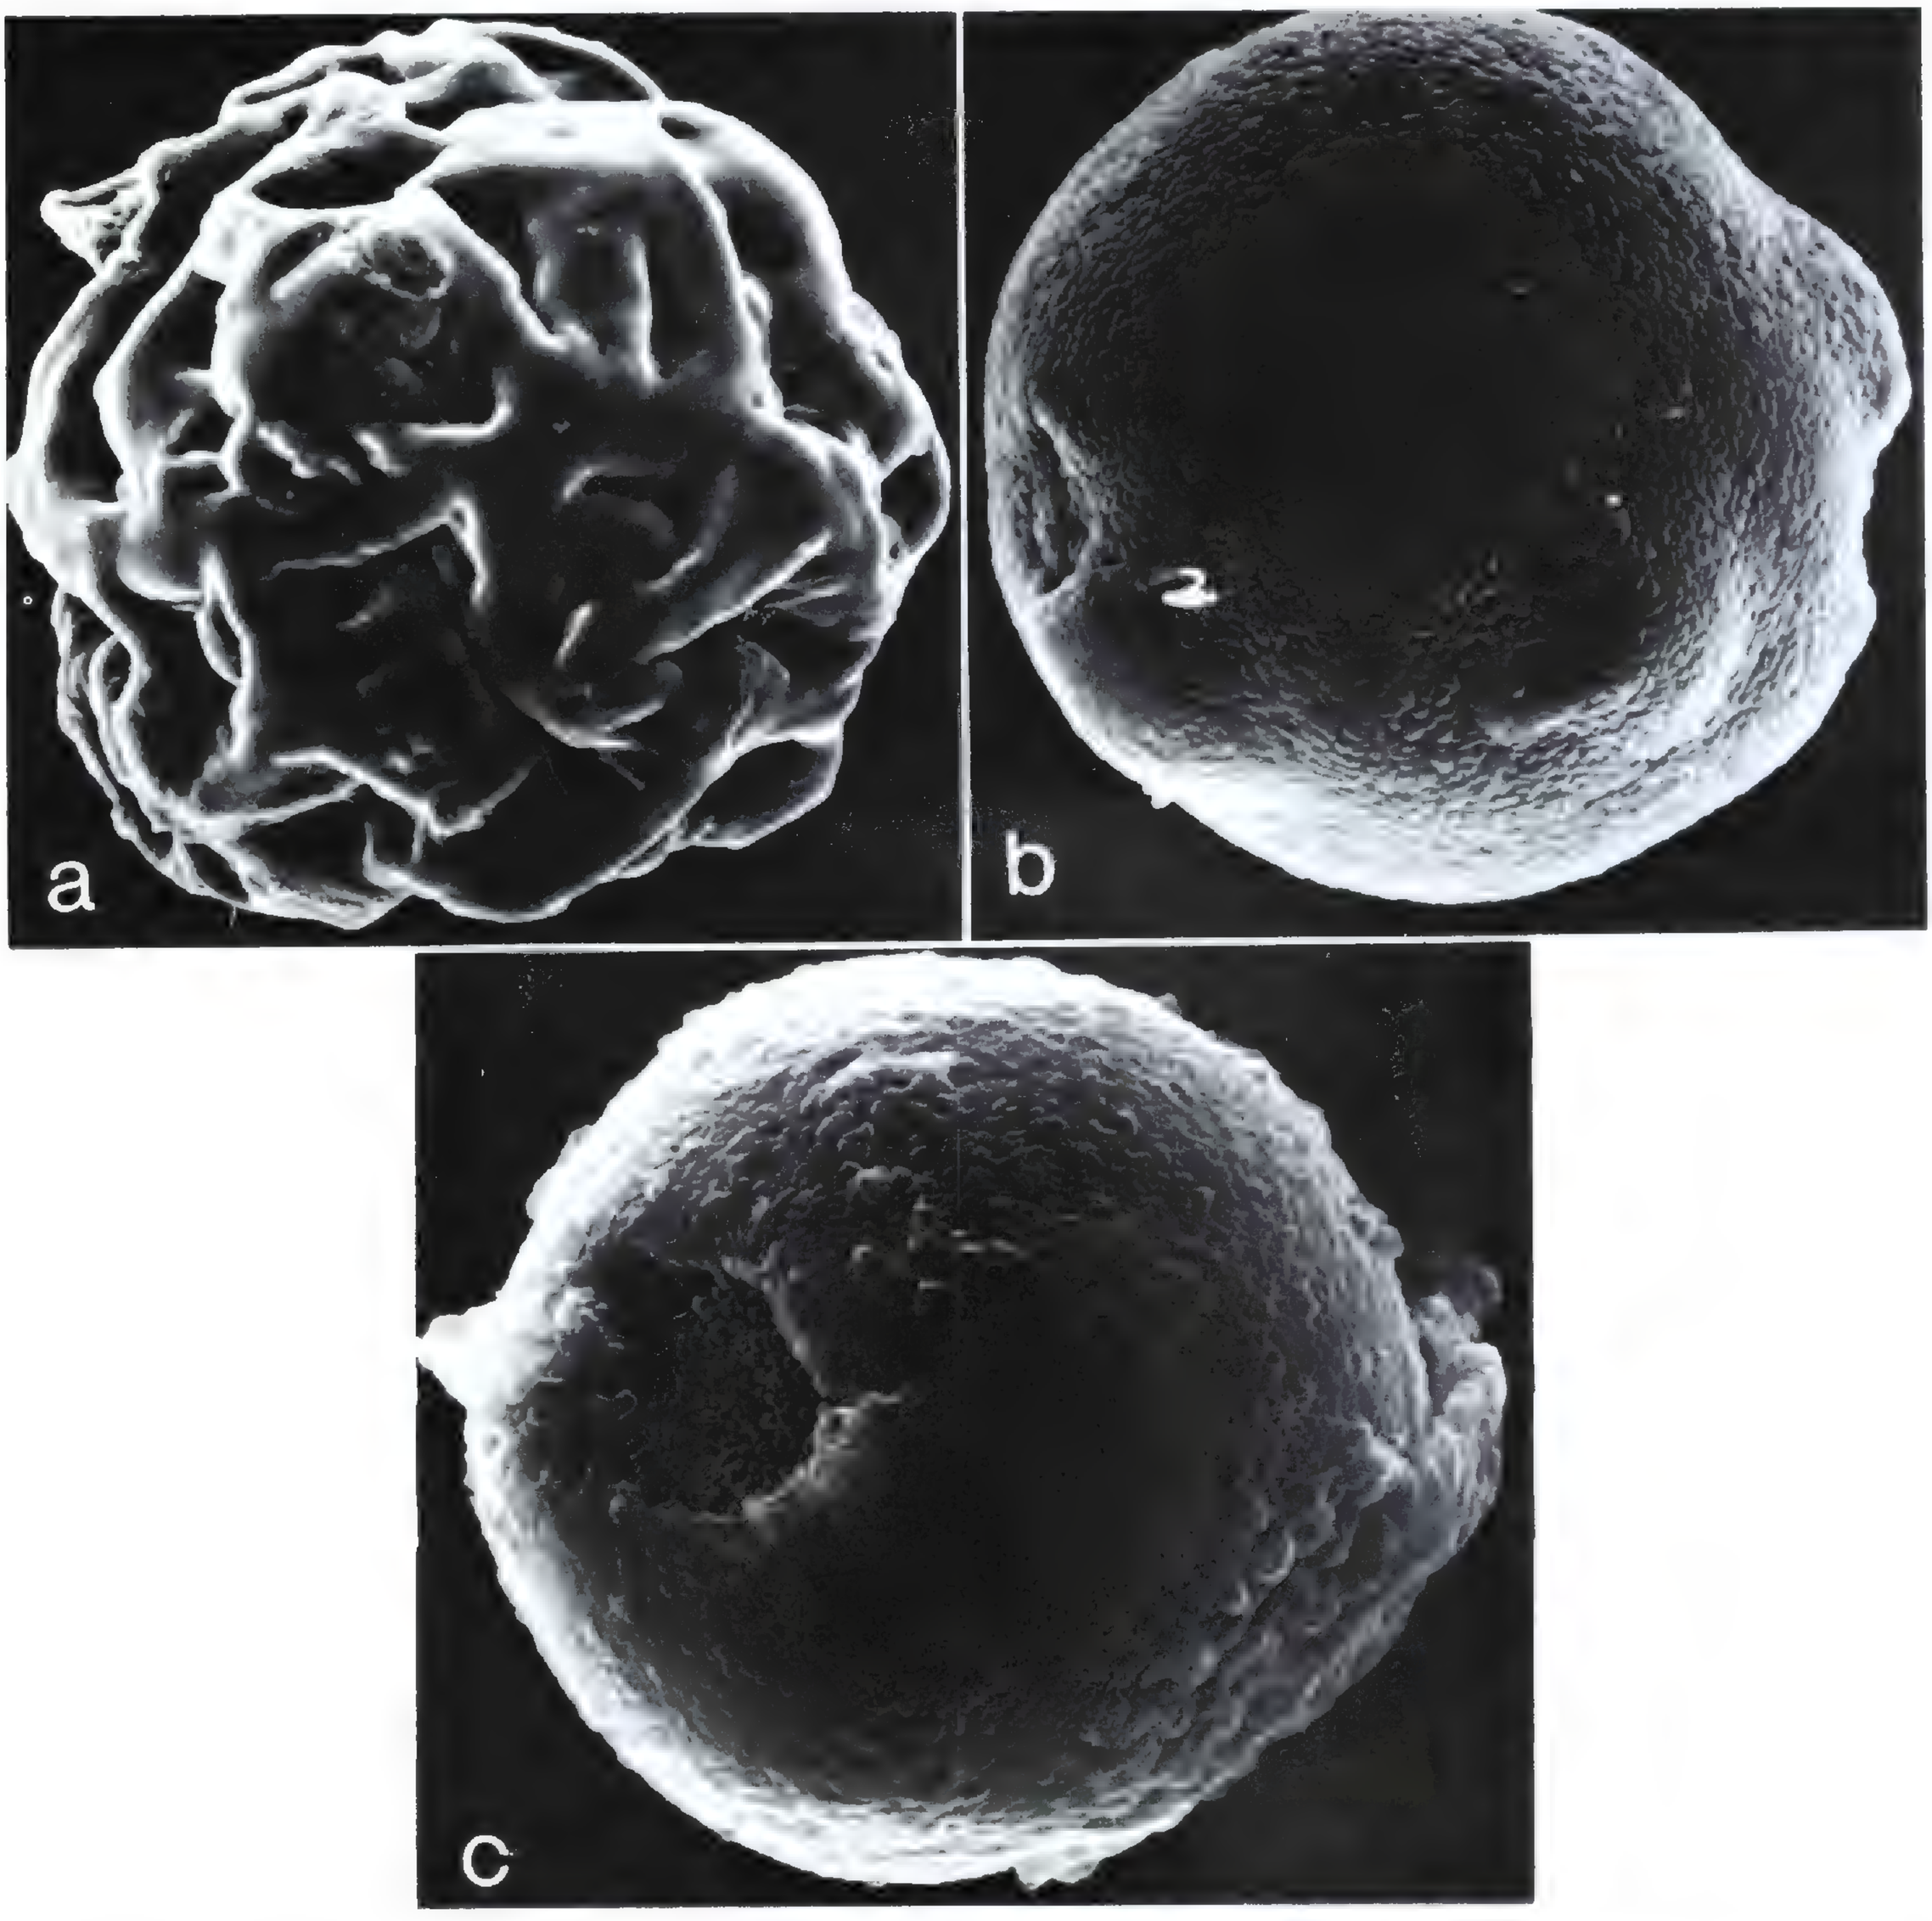

FIGURE 3. Scanning electron microscope (SEM) photomicrographs of *Mendoncia* pollen. — a. *Mendoncia coriacea*, equatorial view, × 1,200 (*Steyermark & G. C. K. & E. Dunsterville 104474*).—b. *M. steyermarkii*, equatorial view, ×1,750 (*Steyermark & G. C. K. & E. Dunsterville 104353*).— c. *M. neblinensis*, equatorial view, ×2,200 (*R. Liesner 15667*).

Mendoncia williamsii is most closely (but distantly) related to *M. sprucei* Lindau. In *M. sprucei* the bracts are ovate and sparingly appressed-hirtellous without; the flowers are usually solitary; and the leaf blades are ovate to oblong-ovate, firmly membranous, and about 6 cm broad. In contrast, in *M. williamsii* the bracts are oblong-lanceolate and densely brown strigose without; the flowers are usually in twos; and the leaf blades are elliptic, chartaceous, and considerably wider (about 7.5 cm broad).

Mendoncia coriacea Wasshausen, sp. nov. TYPE: Venezuela. Bolívar: km 133.5, drenaje del Río Cuyuní, al sur de El Dorado, 1,300–1,380 m, 22–28 Dec. 1970, *Julian A. Steyermark & G. C. K. & E. Dunsterville 104474* (holotype, US; isotype, MO). Figure 2D–F.

Suffrutex volubilis, caulibus subquadrangularibus, glabris. Foliorum lamina elliptica vel oblonga, apice abrupte acuminata et mucronata, basi acuta, coriacea, integra, glabra, costa et venis lateralibus prominentibus subtus; petioli subqudrangulares, glabri; flores 2, axillares; pedi-

celli graciles, glabri, olivacei suffuso marronini; bracteae oblongae, coriaceae, vinaceo-lavandulae viridi-vittatae, apice rotundatae vel obtusae, mucronulatae, extus glabrae et minute rugosae, intus glabrae minute punctatae; corolla alba, in tubo lineis lavandulaceis notato, glabra, limbo obliquo, lobis suborbicularibus, leviter emarginatis; drupa subglobosa, glabra.

Large suffruticose liana, 25–30 m high; stem subquadrangular, glabrous. Leaves on petioles 2–3.5 cm long, subquadrangular, glabrous, the blades subcoriaceous to thick-coriaceous, elliptic to oblong, 8–14 cm long, 3.5–6 cm broad, the tip abruptly acuminate (the tip blunt and terminating in a mucro 1 mm long), acute at base, entire or undulate, both surfaces glabrous, dark green and minutely punctate above, dull green below, the costa and lateral veins (3–5 pairs) obscure above and prominent and raised beneath, the veinlets of the middle lower leaves forming a conspicuous reticulation on the lower surface. Flowers axillary, usually 2 in each axil; pedicels 3–4 cm long, slender, 0.75 mm broad at base, gradually enlarged to 2 mm at tip, glabrous, olive green suffused maroon; bracts coriaceous, vinaceous-lavender with green, oblong, 2.5–3.5 cm long, 1–1.4 cm broad, rounded or obtuse at apex and tipped by a mucro 1 mm long, rounded at base, glabrous and minutely rugose without, glabrous and minutely punctate within; corolla white with lavender stripes in the tube within, glabrous, 4.5 cm long, the tube 4 mm broad at base, narrowed to 3 mm at 10 mm above base, the throat 8 mm broad, the upper lip about 1 cm long, the lobes unequal, suborbicular, 6 mm long and 9 mm broad, shallowly emarginate at apex, the lower lip somewhat shorter than the upper lip; pollen grains 5-colporate (brevissimicolpate), prolate-spheroidal, 58 × 53 μm, exine thick, crassinexious; calyx annular, 0.5 mm long, glabrous; style 2.9 cm long, glabrous; ovary glabrous. Drupe subglobose, dark wine-purple to black, 18 mm long, 15 mm in diam., glabrous.

Distribution. Wooded ridge and tall, moist forest with trees on the average 25–30 m tall, Estado Bolívar, Venezuela, at 1,200–1,380 m.

Paratypes. VENEZUELA. BOLIVAR: between campamento 125 and km 127, between Luepa and Cerro Venamo, 1,200 m, *Steyermark & Nilsson 177* (F, US, VEN); carretera El Dorado–Gran Sabana, La Danta, 1,250 m, *Ruiz-Terán & López-Palacios 11481* (MERF, US).

Mendoncia coriacea is perhaps most closely related to the widespread lowland Amazonian species of Colombia and Peru, *M. pedunculata* Leonard, which differs markedly by having larger (4 cm long, 1.4–1.8 cm broad), violet bracts; membranous, wider (6–10 cm broad) leaf blades; and longer, white corollas marked by reddish brown within and 5 to 6 cm long. In contrast, *M. coriacea* has coriaceous, vinaceous-lavender with green bracts 2.5–3.5 cm long and 1–1.4 cm broad; subcoriaceous to thick-coriaceous leaf blades 3.5–6 cm broad; and shorter (4.5 cm long), white, internally lavender-striped corollas.

NEW SPECIES, NAMES, AND COMBINATIONS IN AMERICAN COMBRETACEAE

A. R. A. Alwan Al-Mayah and C. A. Stace[1]

ABSTRACT

Revision of the family Combretaceae for accounts in eight tropical American floras has revealed the following twelve novelties: *Terminalia chicharronia* subsp. *neglecta* (Bisse) Alwan & Stace, comb. nov.; *T. chicharronia* subsp. *domingensis* (Urban) Alwan & Stace, comb. nov.; *T. chicharronia* subsp. *orientensis* (Monach.) Alwan & Stace, comb. nov.; *T. ramatuella* Alwan & Stace, nom. nov.; *T. virens* (Spruce ex Eichler) Alwan & Stace, comb. nov.; *T. crispialata* (Ducke) Alwan & Stace, comb. nov.; *T. steyermarkii* Alwan & Stace, sp. nov.; *T. kuhlmannii* Alwan & Stace, sp. nov.; *T. uleana* Engl. ex Alwan & Stace, sp. nov.; *T. eichleriana* Alwan & Stace, nom. nov.; *Bucida molineti* (M. Gómez) Alwan & Stace, comb. nov.; and *Buchenavia amazonia* Alwan & Stace, sp. nov.

1. ***Terminalia chicharronia*** Wright ex Sauvalle.

Restricted to Cuba, Haiti, and the Dominican Republic, this species is very variable in the size and shape of the leaves and in the amount of indumentum on the branchlets, leaves, and inflorescence. These characters reveal four reasonably well geographically separated taxa recognized here as subspecies.

Terminalia chicharronia was based on *Chicharronia intermedia* A. Rich. (1846), which in turn was based on *Sagra 185* and *281*. The specimens at G are the best ones, but there is no evidence that Richard saw them. In P there is one sheet with three shoots—two in flower and one in fruit—which Richard did see. The label says "Herbarium Richard. No. 185, *Combretum* sp. nov., Guanabo, Marzo 1829, Coll. R. de la Sagra." The two flowering shoots are here designated as lectotype because in G there is a note from Sagra saying that no. 185 was sent first and was flowering, and no. 281 was sent later (both March 1829) and fruiting. This typification fixes subsp. *chicharronia* as the subspecies with densely pubescent to rufous tomentose leaves with strongly raised venation. It occurs most commonly in eastern Cuba (prov. Oriente), where it is sympatric with the closely related *T. eriostachya* A. Rich., which differs by having larger flowers, longer inflorescences, and glabrous styles. *Terminalia maestrensis* Bisse is here considered to be a synonym.

The other subspecies are as follows:

1a. Subsp. **neglecta** (Bisse) Alwan & Stace, comb. nov. BASIONYM: *T. neglecta* Bisse in Feddes Repert. Spec. Nov. Regni Veg. 85: 607. 1974.

Western and central Cuba (provinces Pinar de Río, Habana, and Las Villas, including Isla de Pinos).

1b. Subsp. **domingensis** (Urban) Alwan & Stace, comb. nov. BASIONYM: *T. domingensis* Urban in Symb. Antill. 7: 524. 1913.

Haiti and Dominican Republic.

1c. Subsp. **orientensis** (Monach.) Alwan & Stace, comb. nov. BASIONYM: *T. orientensis* Monach. in Caribbean Forest. 8: 79. 1974.

Synonyms: *T. nipensis* Alain, *T. aroldoi* Bisse, *T. pachystyla* Borh.

Eastern Cuba (province Oriente, mostly at higher altitude).

2. *Ramatuella* Kunth

This former genus was revised by Exell & Stace (1963), who recognized six species. Subsequent collections have shown that this should be reduced to three. Moreover, although *Ramatuella* is still recognizable by the combination of characters outlined by Exell & Stace, it seems far better reunited with *Terminalia*, as its distinction is based on only one of several combinations of characters found in *Terminalia*. Accordingly, we reduce it to sectional status.

[1] Department of Botany, University of Leicester, Leicester LE1 7RH, England.

2a. **Terminalia** sect. **Ramatuella** (Kunth) Alwan & Stace, comb. nov. BASIONYM: *Ramatuella* Kunth, Nov. Gen. Sp. 7: 253. 1825 ("*Ramatuela*," based on misspelling of "Ramatuelle").

2b. **Terminalia ramatuella** Alwan & Stace, nom. nov. pro *Ramatuella argentea* Kunth, Nov. Gen. Sp. 7: 254, tab. 656. 1825.

The epithet *argentea* cannot be transferred to *Terminalia* as there already exists *T. argentea* C. Martius (1824), a very different species, from Brazil, Paraguay, and Bolivia.

2c. **T. virens** (Spruce ex Eichler) Alwan & Stace, comb. nov. BASIONYM: *Ramatuella virens* Spruce ex Eichler in C. Martius, Fl. Bras. 14(2): 100, tab. 26, fig. 2. 1867.
Synonyms: *R. maguirei* Exell & Stace, *R. latifolia* Maguire.

2d. **T. crispialata** (Ducke) Alwan & Stace, comb. nov. BASIONYM: *Ramatuella crispialata* Ducke, Arq. Inst. Biol. Veg. 2: 65. 1935.
Synonym: *R. obtusa* (Maguire) Exell & Stace.

3. **Terminalia steyermarkii** Alwan & Stace, sp. nov. TYPE: dwarf woody plant with branches spreading from near ground, only 0.5–1 m tall; flowers creamy-buff; leaves crowded at tip of branch, coriaceous, dull green above, gray-sericeous below, the apical youngest leaves buff-silvery sericeous; filaments greenish white; ovary and calyx gray-green; perianth pale green. Venezuela. Bolívar: Cumbre de Cerro Guaiquinima, sector nororiental, entre las brazos nororiental del Río Carapo, en una meseta arenosa pedregosa y cubierta con vegetación muy esparcida, 5°54′N, 63°25′W, 980 m, 30 May 1978, *Steyermark, Berry, G. & E. Dunsterville 117521* (holotype, LTR; isotype, VEN, not seen).

Frutex 0.5–1 m altus, ramulis dense villosis. Folia spiraliter ordinata ad ramulorum apices congesta; petiolus ca. 5–10 mm longus, dense sericeus; lamina coriacea, obovata vel elliptico-obovata, (3–)5–11 × 3–6.5 cm, apice retusa vel rotundata, basi cuneato-obtusa in petiolo decurrente, supra pubescens, subtus holosericeo argentea, venis lateralibus 7–9-paribus; venatio brochidodroma inconspicua. Inflorescentiae axillares, spicatae, pedunculus 4–5 cm longus, dense pubescens; rachis 4 cm longa, dense tomentosa. Flores 4–5-meri; receptaculum inferum 3.5 mm longum, dense villosum; receptaculum superum 2 × 4 mm, dense pubescens; calycis lobi 5 vel 4, 1.5 mm longi; stamina 8 vel 10, exserta ad 4–5 mm; stylus 5–6 mm longus, ad medium usque pilosus. Fructus ignotus.

Terminalia steyermarkii is one of those remarkable coriaceous-leaved species of sects. *Ramatuella* and *Pachyphyllum* Maguire & Exell that are confined to the vicinity of the watershed between the Río Orinoco and the northern tributaries of the Amazon. It differs from all but *T. ramatuella* by having a densely sericeous lower leaf surface, and from *T. ramatuella* by having an apparently dwarfer habit, broader and thicker leaves, and more elongated rachis.

Terminalia steyermarkii is known only from the type collection. Without fruits its precise affinities are uncertain, but the elongated rachis with bisexual flowers borne along its length suggests sect. *Pachyphyllum* rather than sect. *Ramatuella.*

4. **Terminalia kuhlmannii** Alwan & Stace, sp. nov. TYPE: Brazil. Espirito Santo: Goytacazes, Rio Doce. n.v. "Pelada," arvore frequente no mato, da madelta a provei tavel, 16 Dec. 1943, *Kuhlmann 06688* (holotype, RB 62982; isotypes, NY, RB).

Arbor. Folia spiraliter ordinata ad ramulorum apices congesta; petiolus 1–2 cm longus, glaber vel sparse pubescens, eglandulosus; lamina chartacea, 5–12 × 3–6 cm, obovata, apice subacuta vel acuminata, basi acuta, supra glabra, subtus ± glabra; venatio brochidodroma conspicua, venis secundariis subtus prominentibus 5–8 paribus, venis tertiariis subtus reticulatis, venulis conspicuis vix prominentibus. Pedunculus (in fructu) 2–3.5 cm longus, pubescens; rachis (in fructu) 2–3.5 cm longa, dense pubescens. Fructus 2-alatus, transversali oblongus, 1.2–1.7 × 3.5–4.6 cm, dense pubescens, corpore 3–4 mm lato, alis oblongis 1.4–2.1 cm latis.

Terminalia kuhlmannii belongs to sect. *Diptera* (Eichler) Engl. & Diels, which includes four other South American species. Of these, *T. januariensis* DC. and *T. guyanensis* Eichler have much larger glabrous fruits; *T. argentea* C. Martius has ovate leaves, and leaf lower surface and fruits usually tomentose at least when young; and *T. phaeocarpa* Eichler has larger leaves usually acute to rounded at apex with eucamptodromous venation, and usually glabrous fruits. *Terminalia kuhlmannii* most closely resembles *T. guyanensis*, but this is geographically remote and differs additionally in its narrower leaves with less conspicuous venation and shorter inflorescence.

A flowering specimen (*Silva 356*, LTR & CVRD) from close to the type locality probably also belongs here. It is a tree of 29 m also known as "Pelado." The flowers are densely pubescent, cream, and with styles pubescent to near the apex. Another flowering specimen (*Almeida & Santos 191*, LTR &

CEPEC), from near Ilheus, Bahia (ca. 550 km north of the former) may also be the same species; it has peduncles up to 6 cm and rachises up to 7 cm, but otherwise is very similar.

5. **Terminalia uleana** Engl. ex Alwan & Stace, sp. nov. TYPE: Brazil. St. Catarina: Baum im Ufer des Capivary, Tubarão, Jan. 1889, *E. Ule 1004* (holotype, HBG; isotypes, B (destroyed, photo F), P, US).

Arbor? Folia alternata, non congesta; petiolus 1 cm longus, pubescens vel dense pubescens, eglandulosus; lamina subcoriacea, 5–12 × 2 5 cm, obovata vel anguste obovata, apice acuminata vel acuta, basi cuneata, supra pubescens vel glabrescens, subtus pubescens; venatio eucamptodromo-brochidodroma; venae secundariae infra prominentes, 5–9 paribus; venae tertiariae fortuito reticulatae, conspicuae; areolae imperfectae. Flores ignoti. Fructus bialatus, transversali oblongus, 1.3–1.5 × (2.5–)3–4.5 cm, glaber; corpus ovato-ellipticum, 1.5 × 0.8 cm, protuberans vel parum carinatum; alae latiores quam longae, 1.3–1.7 × 1.3–2 cm, deorsum curvatae.

Engler wrote the name "*Uleana*" on the sheet at B but did not publish it. Also written on the sheet is the idea that the species is related to *T. argentea*. The new species belongs to sect. *Australes* Engl. & Diels, itself close to sect. *Diptera*, which contains *T. argentea*. Of the species in sect. *Australes*, *T. uleana* differs from *T. australis* Cambess. and *T. reitzii* Exell in fruit shape and from *T. triflora* (Griseb.) Lillo by having wider leaves and wider fruits with a differently shaped wing. The fruit wing of *T. uleana* is often curved downward (retrorsely), and this character is diagnostic; a third rudimentary wing is often present. The species has not been found since 1889.

6. **Terminalia eichleriana** Alwan & Stace, nom. nov. pro *T. punctata* Eichler in C. Martius, Fl. Bras. 14(2): 85. 1867, nom. illegit, non Roth (1821), nec Spruce ex Eichler (1867) (nom. syn. pro *Buchenavia punctata* Eichler). TYPE: Brazil. Bahia: Serra d'Acurra, *Blanchet 2794* (lectotype, BR; isolectotypes, BM, BP, BR, F, FI, G, K, LE, P, RB). The specimen chosen as lectotype was annotated by Eichler, who did not see fruits, although the isolectotype at G does bear fruits. The isolectotype at FI has the additional data: "Certão do R. S. Francesco, 1838." We know of several later collections, all from the state of Bahia.

Terminalia eichleriana belongs to sect. *Actinophyllae* Engl. & Diels and closely resembles *T. fagifolia* C. Martius in vegetative characters. The leaves usually differ in having 3–5 (vs. 5–12) pairs of lateral veins with a narrower angle of divergence. The fruits are very distinct: in *T. eichleriana* the 3(4) wings are 0.5–0.8 × 0.4–0.5 cm, while in *T. fagifolia* the 2 wings are 0.8–1.3 × 0.5–1.3 cm.

7. **Bucida molineti** (M. Gómez) Alwan & Stace, comb. nov. BASIONYM: *Terminalia molineti* M. Gómez, Anales Soc. Esp. Hist. Nat. 19: 244. 1890, nom. nov. pro *Bucida angustifolia* A. Rich., Hist. Phys. Cuba, Pl. Vasc. 521. 1846, and A. Rich. ex Griseb., Cat. Pl. Cub. 109. 1866, non DC. (1828). We have seen no (presumably Sagra) specimens connected with Richard's 1846 publication, but the specimen of *Wright 2573* at G, labeled "*Bucida angustifolia* Rich. (non DC.) ex Griseb. Cat. Cub. p. 109" is the basis for Grisebach's publication and can be selected as the lectotype of *B. molineti*. De Candolle's *Bucida angustifolia* is *Terminalia amazonia* (J. Gmel.) Exell (type: *Perrottet s.n.*, French Guiana, G).

Terminalia spinosa Northrop, Mem. Torrey Bot. Club 12: 54, tab. 13. 1902, non Engl. (1895).
Bucida spinosa (Northrop) Jennings, Ann. Carnegie Mus. 11: 201. 1917.
B. ophiticola Bisse, Feddes Repert. Spec. Nov. Regni Veg. 85(9–10): 605. 1974.
B. correlliana Wilbur, Taxon 37: 467. 1988, nom. nov. pro *Terminalia spinosa* Northrop, non Engl.

Bucida spinosa (Northrop) Jennings is illegitimate since its basionym (*Terminalia spinosa* Northrop) is a later homonym. Realizing this, Delendick (1984) proposed that *B. spinosa* Jennings be treated as a new species dating from 1917, not realizing that the earlier epithet *molineti* existed and should be used. Moreover, recently the common procedure of legitimizing names in the way that Delendick proposed has been called into question (Wilbur, 1988). Wilbur argued that the original intention of the combining author (Jennings) should not be ignored, and that names should therefore not be "rescued" in the way that Delendick proposed. Accordingly, Wilbur proposed the new name *B. correlliana*. Even if Wilbur's argument is accepted, the name *B. ophiticola* predates *B. correlliana*.

8. **Buchenavia amazonia** Alwan & Stace, sp. nov. TYPE: Colombia. Caqueta: wet tropical forest of Amazon Basin, 1 km N of Solano, 8 km southeast of Tres Esquinas, on Río Caqueta below mouth of Río Orteguaza, 200 m.

Tree 8 m high, 20 cm dbh; bark brown, smoothish; fruits green, oblong. Wet soil of old channel, near river; grass pasture of cleared lowland forest and in lowland forest. 7 Mar. 1945, *Little & Little 9626* (holotype, US; isotype, COL).

Frutex vel arbor parva, 2–8 m alta. Folia spiraliter ordinata ad ramulorum apices congesta; petiolus 0.8–2 cm longus, dense rufo-pubescens, saepe biglandulosus; lamina chartacea, (2–)3–8(–12.5) × 1.5–4(–5.5) cm, obovata vel anguste obovata vel elliptica, apice rotundato-obtusa vel acuminato-subacuta, basi cuneata, supra fere glabra, subtus fere glabra, venis primariis secundariisque sparse pubescentibus exceptis; venatio brochidodroma vel eucamptodromo-brochidodroma; costa media infra prominens; venae secundariae infra prominentes, 5–7 paribus; venae tertiariae irregulariter percurrentes, conspicuae; areolae parvae, perfecte effectae. Inflorescentiae elongato-spicatae; pedunculus gracilis, 0.5–1.5 cm longus, rufo-pubescens; rhachis 1.5–3 cm longa, pubescens. Flores 2–3(–4) × 2–3 mm; receptaculum inferum 1–2 mm longum, infime tomentosum; receptaculum superum glabrum. Fructus ellipsoideo-ovoideus, 1.3–2 × 0.7–1.2 cm, apice rotundato-obtuso vel subacuto vel breviter apiculato, basi rotundato-obtusa, sparse puberula; endocarpium in sectione transversali circulare, longitudinaliter sulcatum.

Other specimens have been seen from Colombia (Caqueta), Brazil (Amazonas), Peru (Loreto), and Ecuador (Napo), and a specimen possibly of this species from French Guiana.

This species resembles *B. oxycarpa* (C. Martius) Eichler in leaf characters, but the fruit is pubescent and not beaked. The fruit resembles that of *B. viridiflora* Ducke, but the leaves have a much closer and more conspicuous vein reticulation, and are thinner in texture and usually broader.

SOLANUM ALLOPHYLLUM (MIERS) STANDL. AND THE GENERIC DELIMITATION OF *CYPHOMANDRA* AND *SOLANUM* (SOLANACEAE)[1]

Lynn Bohs[2]

ABSTRACT

Solanum allophyllum has previously been placed in *Cyphomandra* and in *Solanum*. This species has a number of morphological features not found in *Cyphomandra*, but has been included in the genus because it has a similar growth habit, three-leaved sympodial units with inflorescences in branch forks, and tapered anthers with an abaxial thickening. When each of these characters is closely examined, however, important differences are found between the taxa, indicating that the features they share may not be structurally homologous. New evidence derived from crossing studies and cytological investigations also supports the exclusion of *S. allophyllum* from *Cyphomandra*. *Solanum allophyllum* is self-compatible, whereas all but the single domesticated species of *Cyphomandra* are self-incompatible, and the chromosomes of *Cyphomandra* are about 2.5 to 5.5 times larger than those of *S. allophyllum*. The anther morphology, self-compatibility, and small chromosomes are all consistent with placement of this species in *Solanum*.

INTRODUCTION AND TAXONOMIC HISTORY

The generic placement of the species here known as *Solanum allophyllum* (Miers) Standl. has long been a source of confusion. Various workers have placed this species in *Solanum*, *Cyphomandra*, and *Bassovia*. It was first described as *Pionandra allophylla* by Miers (1854) in Seemann's *Botany of the Voyage of the H.M.S. Herald. Pionandra*, erected by Miers in 1845, is synonymous with Sendtner's genus *Cyphomandra*, created a few months earlier (Sendtner, 1845). Accordingly, *P. allophylla* was transferred to *Cyphomandra* by Hemsley in 1882. Standley transferred *Cyphomandra allophylla* to *Solanum* in 1927 without explanation.

Georg Bitter, unaware of Miers's species, independently described the species as *Solanum ellipsoideibaccatum* Bitt. in 1913. He noted that the tapered anthers with small terminal pores resemble those of *Solanum* subg. *Leptostemonum* (Dun.) Bitt. but surmised that his species probably represented a new section of *Solanum*. In 1914, Bitter received specimens illustrating the lobed leaves that often occur on the lower branches in this species. He emended his original description to include these lobed leaves and described a new variety, var. *ficilobum* Bitt., from a specimen exhibiting almost exclusively lobed leaves. Pittier (1947) later transferred *Solanum ellipsoideibaccatum* to the genus *Bassovia*, an error that Hunziker (1969) later corrected. *Solanum ellipsoideibaccatum* and its variety *ficilobum* are regarded here as synonyms of the earlier name *Solanum allophyllum* (Miers) Standley.

Standley's placement of the species in *Solanum* was followed in the older literature (Morton, 1944; Romero-Castañeda, 1965; Standley, 1928), but more recent workers have interpreted it as belonging in *Cyphomandra* (Bohs, 1986, 1988; Child, 1984; D'Arcy, 1973). All those who have included the species within *Cyphomandra* have noted its atypical anther structure, but placed it in *Cyphomandra* on the basis of other similarities. Child (1984) called attention to its anomalous features

[1] I thank Alan Child for sending seeds of *S. allophyllum* and several *Cyphomandra* species and for his insightful discussions on relationships in *Solanum* and *Cyphomandra*. I also thank Dave Barrington, John Sperry, and Mel Tyree for use of their lab facilities, and Greg Anderson, Dave Barrington, W. G. D'Arcy, George Rogers, and John Sperry for reading and commenting on the manuscript.

[2] Work done at: Pringle Herbarium, Marsh Life Science Building, University of Vermont, Burlington, Vermont 05405, U.S.A. Present address: Department of Biology, University of Utah, Salt Lake City, Utah 84112, U.S.A.

when he erected *Cyphomandra* sect. *Allophylla* Child to accommodate this species and the allied *Cyphomandra phytolaccoides* (Rusby) Child (= *Solanum mapiriense* Bitter).

Why has the generic placement of this species been so uncertain? Though *S. allophyllum* differs from *Cyphomandra* in a number of morphological characters, it has been considered as a *Cyphomandra* because, at least superficially, this species shares with *Cyphomandra* the very features that have been used to distinguish *Cyphomandra* from *Solanum*. Both *S. allophyllum* and *Cyphomandra* have: 1) a growth habit characterized by a single erect trunk and a spreading crown of three main lateral branches, 2) three-leaved sympodial units with the inflorescences situated mainly in branch forks, and 3) tapered anthers that are thickened on the abaxial surface. Growth habit and branching pattern have been recently proposed as new characters that distinguish *Cyphomandra* from *Solanum* (Bohs, 1986). Anther structure traditionally separates the two genera (Sendtner, 1845). Herein I reexamine the morphological features of *Cyphomandra* and *S. allophyllum* with emphasis on these three proposed generic characters. New information about the breeding system and morphology of the chromosomes, pollen, and seeds of *S. allophyllum* and *Cyphomandra* is also compared. These investigations help to ascertain the generic position of this species and shed new light upon the critical characters that separate *Solanum* and *Cyphomandra*.

Materials and Methods

Morphological studies were carried out using living plants, and dried specimens from the following herbaria: A, BM, C, E, F, GH, K, M, MO, NY, P, US, and WIS. Voucher information for greenhouse material is given in the Appendix.

Growth habit is defined by reference to the architectural models of Hallé et al. (1978). This system takes into account the dynamic aspects of plant growth rather than simply considering the shape of a plant at any one time. Terminology relating to architecture and branching pattern likewise follows Hallé et al. (1978).

Compatibility studies were conducted on plants growing in pollinator-free greenhouses at Harvard University and at the University of Vermont. One to several accessions were grown of each species. Plants were either selfed or outcrossed, between accessions and between individuals of the same accession, by tapping pollen onto a clean glass slide and rubbing it across the stigma of the female parent.

For observations of meiotic chromosomes, flower buds were fixed in Farmer's solution (3 : 1 absolute ethanol : glacial acetic acid) or Carnoy's fixative (6 : 3 : 1 absolute ethanol : chloroform : glacial acetic acid) shortly after sunrise. Preparations were stained with 1–2% acetocarmine and squashed in Hoyer's solution. Root tips for mitotic chromosome observations were pretreated for up to 24 hours in a saturated solution of paradichlorobenzene at approximately 4°C, then fixed in Farmer's solution for up to 24 hours. Root tips were then stored in 70% ethanol until use, hydrolyzed in 1 N HCl for 10 minutes at 60°C, and stained as above.

Histological preparations of anthers were obtained from flowers that had been fixed in FAA, dehydrated in an alcohol series, embedded in Paraplast, sectioned, and stained with safranin/fast green.

Pollen measurements were made from fresh pollen samples obtained from greenhouse plants. The grains were shaken into a mixture of 1–2% acetocarmine and Hoyer's solution and allowed to stand for exactly 10 days before measurement. Measurements of the polar and equatorial axes on 30 grains per sample were made from a 400× camera lucida projection onto a Zeiss ZIDAS digitizer. Pollen diameter was measured on stained grains only, and was taken as the distance between the innermost layers of the pollen grain wall. Pollen volume was calculated using the formula for the volume of an ellipsoid, $V = \pi PE^2/6$, where E is the equatorial diameter and P is the polar diameter. An analysis of variance revealed no significant difference between equatorial diameter as measured in polar and equatorial views, so P and E were measured in equatorial view only.

Pollen samples for scanning electron microscope (SEM) photos were taken from dried herbarium material. The grains were mounted on the stub with double-stick tape and coated with gold-palladium. Fresh pollen from greenhouse plants that was critical-point dried and coated appeared collapsed under the SEM.

Results

Distribution, Ecology, and Morphology

Table 1 compares the morphological and ecological characteristics of *S. allophyllum* and *Cyphomandra* discussed below.

The ecological distribution, phenology, and generation time differ greatly in *S. allophyllum* and

TABLE 1. Comparison of morphological and other characters in *Cyphomandra* and *Solanum allophyllum* (details in text).

	Cyphomandra	*Solanum allophyllum*
Habitat	Mesic forest	Seasonally dry forest
Generation time	Usually > 1 yr.	< 1 yr.
Height	Up to 10 m	Up to 1.5 m
Leaf bases	Usually cordate or truncate, rarely decurrent	Subcordate to truncate, decurrent
Numer of flowers per inflorescence	> 10	4–6
Pedicel length	> 10 mm	4–6 mm
Corolla shape	Urceolate, campanulate, or stellate, not plicate	Rotate-stellate and plicate
Fruit color	Red, yellow, orange, purple, or green, never white	White to orange
Fruit shape	Not laterally compressed	Laterally compressed
Architectural model	Intermediate between Prevost's and Nozeran's models	"Fragment" of Prevost's or Nozeran's models
Sympodial units	3–4-leaved, rarely 5-leaved	3-leaved
Anthers	Tapered or not, with distinct and enlarged connective	Tapered, without enlarged connective

Cyphomandra. *Solanum allophyllum* has been collected from a single site in Honduras and is more abundant from Costa Rica and Panama through northwestern South America (Fig. 1). Although the plants are found in a variety of habitats, in Costa Rica and Panama the species seems to grow in drier sites than *Cyphomandra* species, which are almost always mesic-forest dwellers. No herbarium collections of this species from Costa Rica or Panama were made in the months of January–March, the dry season in these regions (Coen, 1983; Croat, 1978). This may indicate that *S. allophyllum* persists by losing its leaves during the dry season and perennating via its roots or larger shoots, but further field studies of this species are needed to ascertain its phenology. In the greenhouse the plants flower and fruit within five months from planting. This generation time is much shorter than most cultivated cyphomandras, which often take several years to reach reproductive age. *Solanum allophyllum* is a weakly woody shrub that rarely grows over 1.5 m tall (Fig. 2), in contrast to the majority of *Cyphomandra* species, which develop abundant secondary xylem and may reach heights of up to 10 m.

The subcordate to truncate leaf bases of *S. allophyllum* are decurrent along the petiole (Fig. 3). The leaves of *Cyphomandra* usually have cordate or less frequently truncate bases; decurrent leaf bases occur only in *C. fragilis* Bohs.

The inflorescences of *S. allophyllum* are unbranched and bear 4–6 flowers on short pedicels 4–6 mm long. Those of *Cyphomandra* can be branched or unbranched, typically bear more than 10 flowers, and have pedicels longer than 10 mm. The shape of the corolla of *S. allophyllum* can best be described as rotate-stellate (sensu Correll, 1962): fairly long corolla lobes are present, but these are connected at the base by abundant interpetalar tissue that is plicate in the bud (Fig. 4). This type of corolla is often seen in *Solanum* subg. *Potatoe* (G. Don) D'Arcy. In contrast, the corolla of *Cyphomandra* has various shapes, but never rotate-stellate or plicate.

Solanum allophyllum produces some of the most distinctive fruits in the Solanaceae. At maturity, they are glabrous and white or occasionally orange mottled with green or purplish markings. The fruits are ellipsoidal or oblong in outline, and are laterally compressed and appear elliptic in cross section (Fig. 5). Within them are many very small flattened seeds and 3–6 small stone cell aggregates. The fruits differ from those of all species of *Cyphomandra* in color and shape, and the seeds are much smaller and more numerous than those of any species of *Cyphomandra*. In the greenhouse and presumably also in the field, the fruits fall to the ground while still hard and bitter and then ripen for several weeks before becoming soft and palatable and emitting a strong sweet odor. They are most likely dispersed by ground-dwelling animals. Those of *Cyphomandra* are held on the tree and

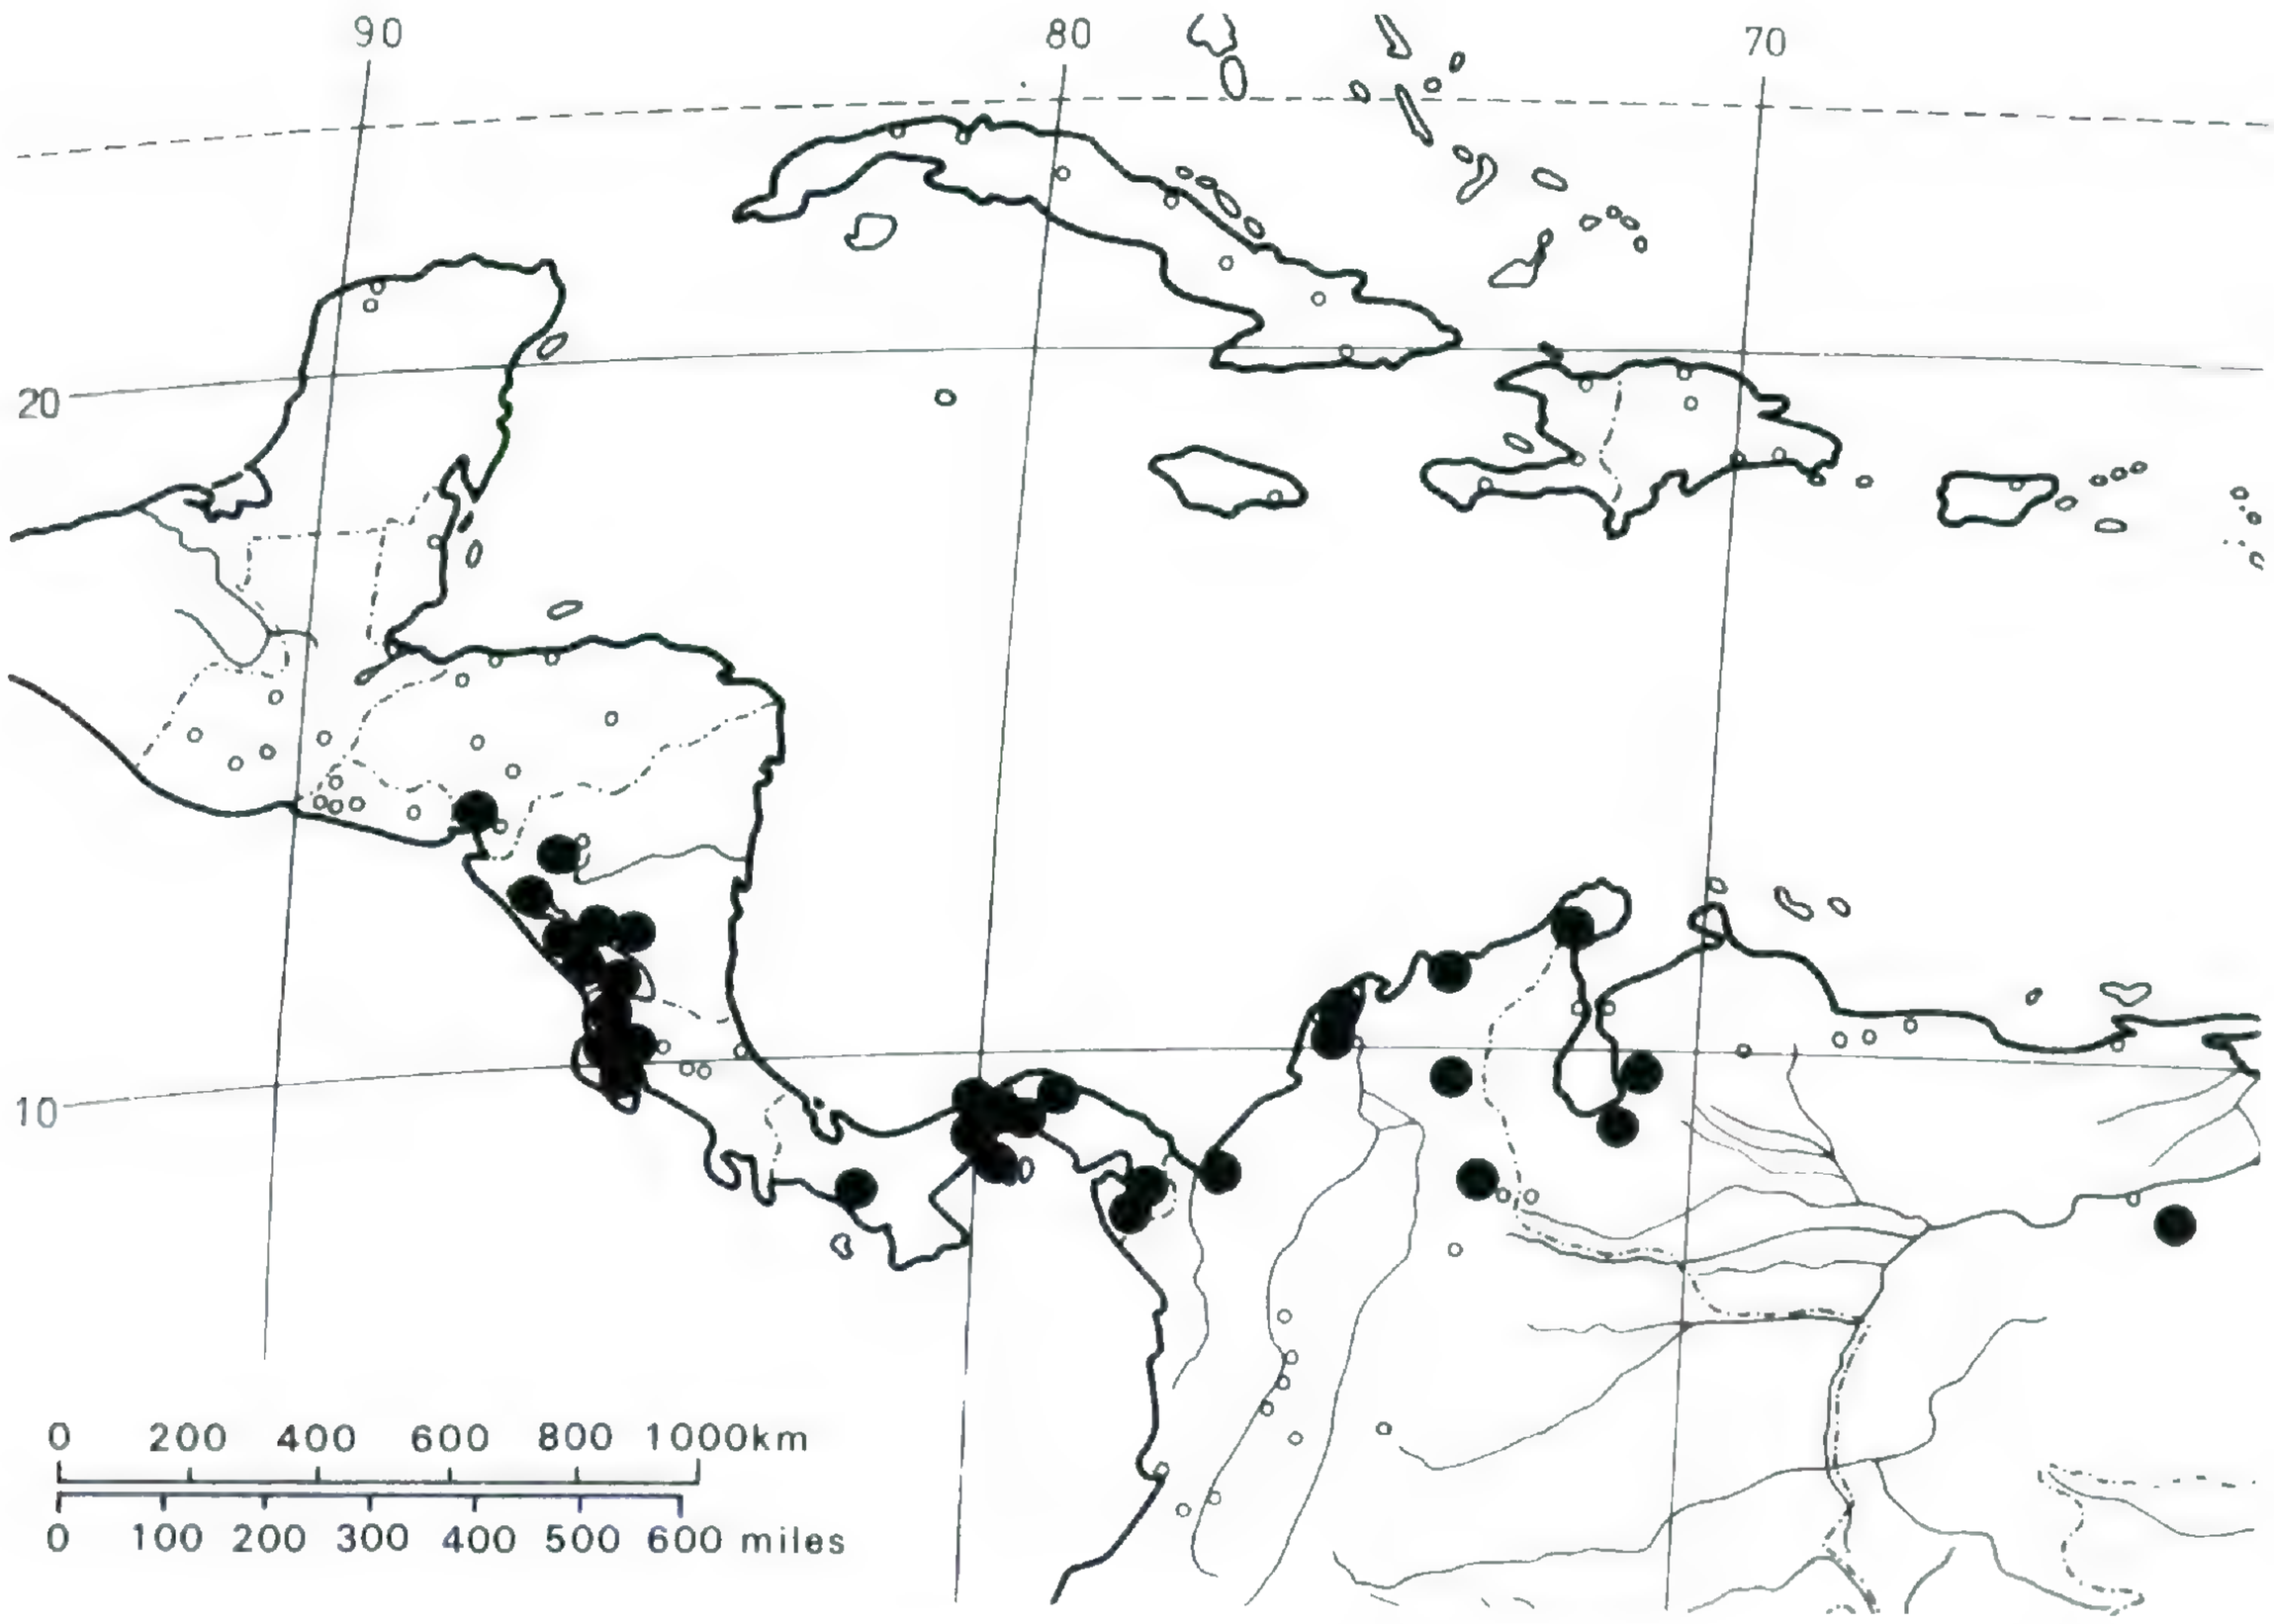

FIGURE 1. Distribution of *Solanum allophyllum*. (Base map copyright 1979 by the University of Utrecht.)

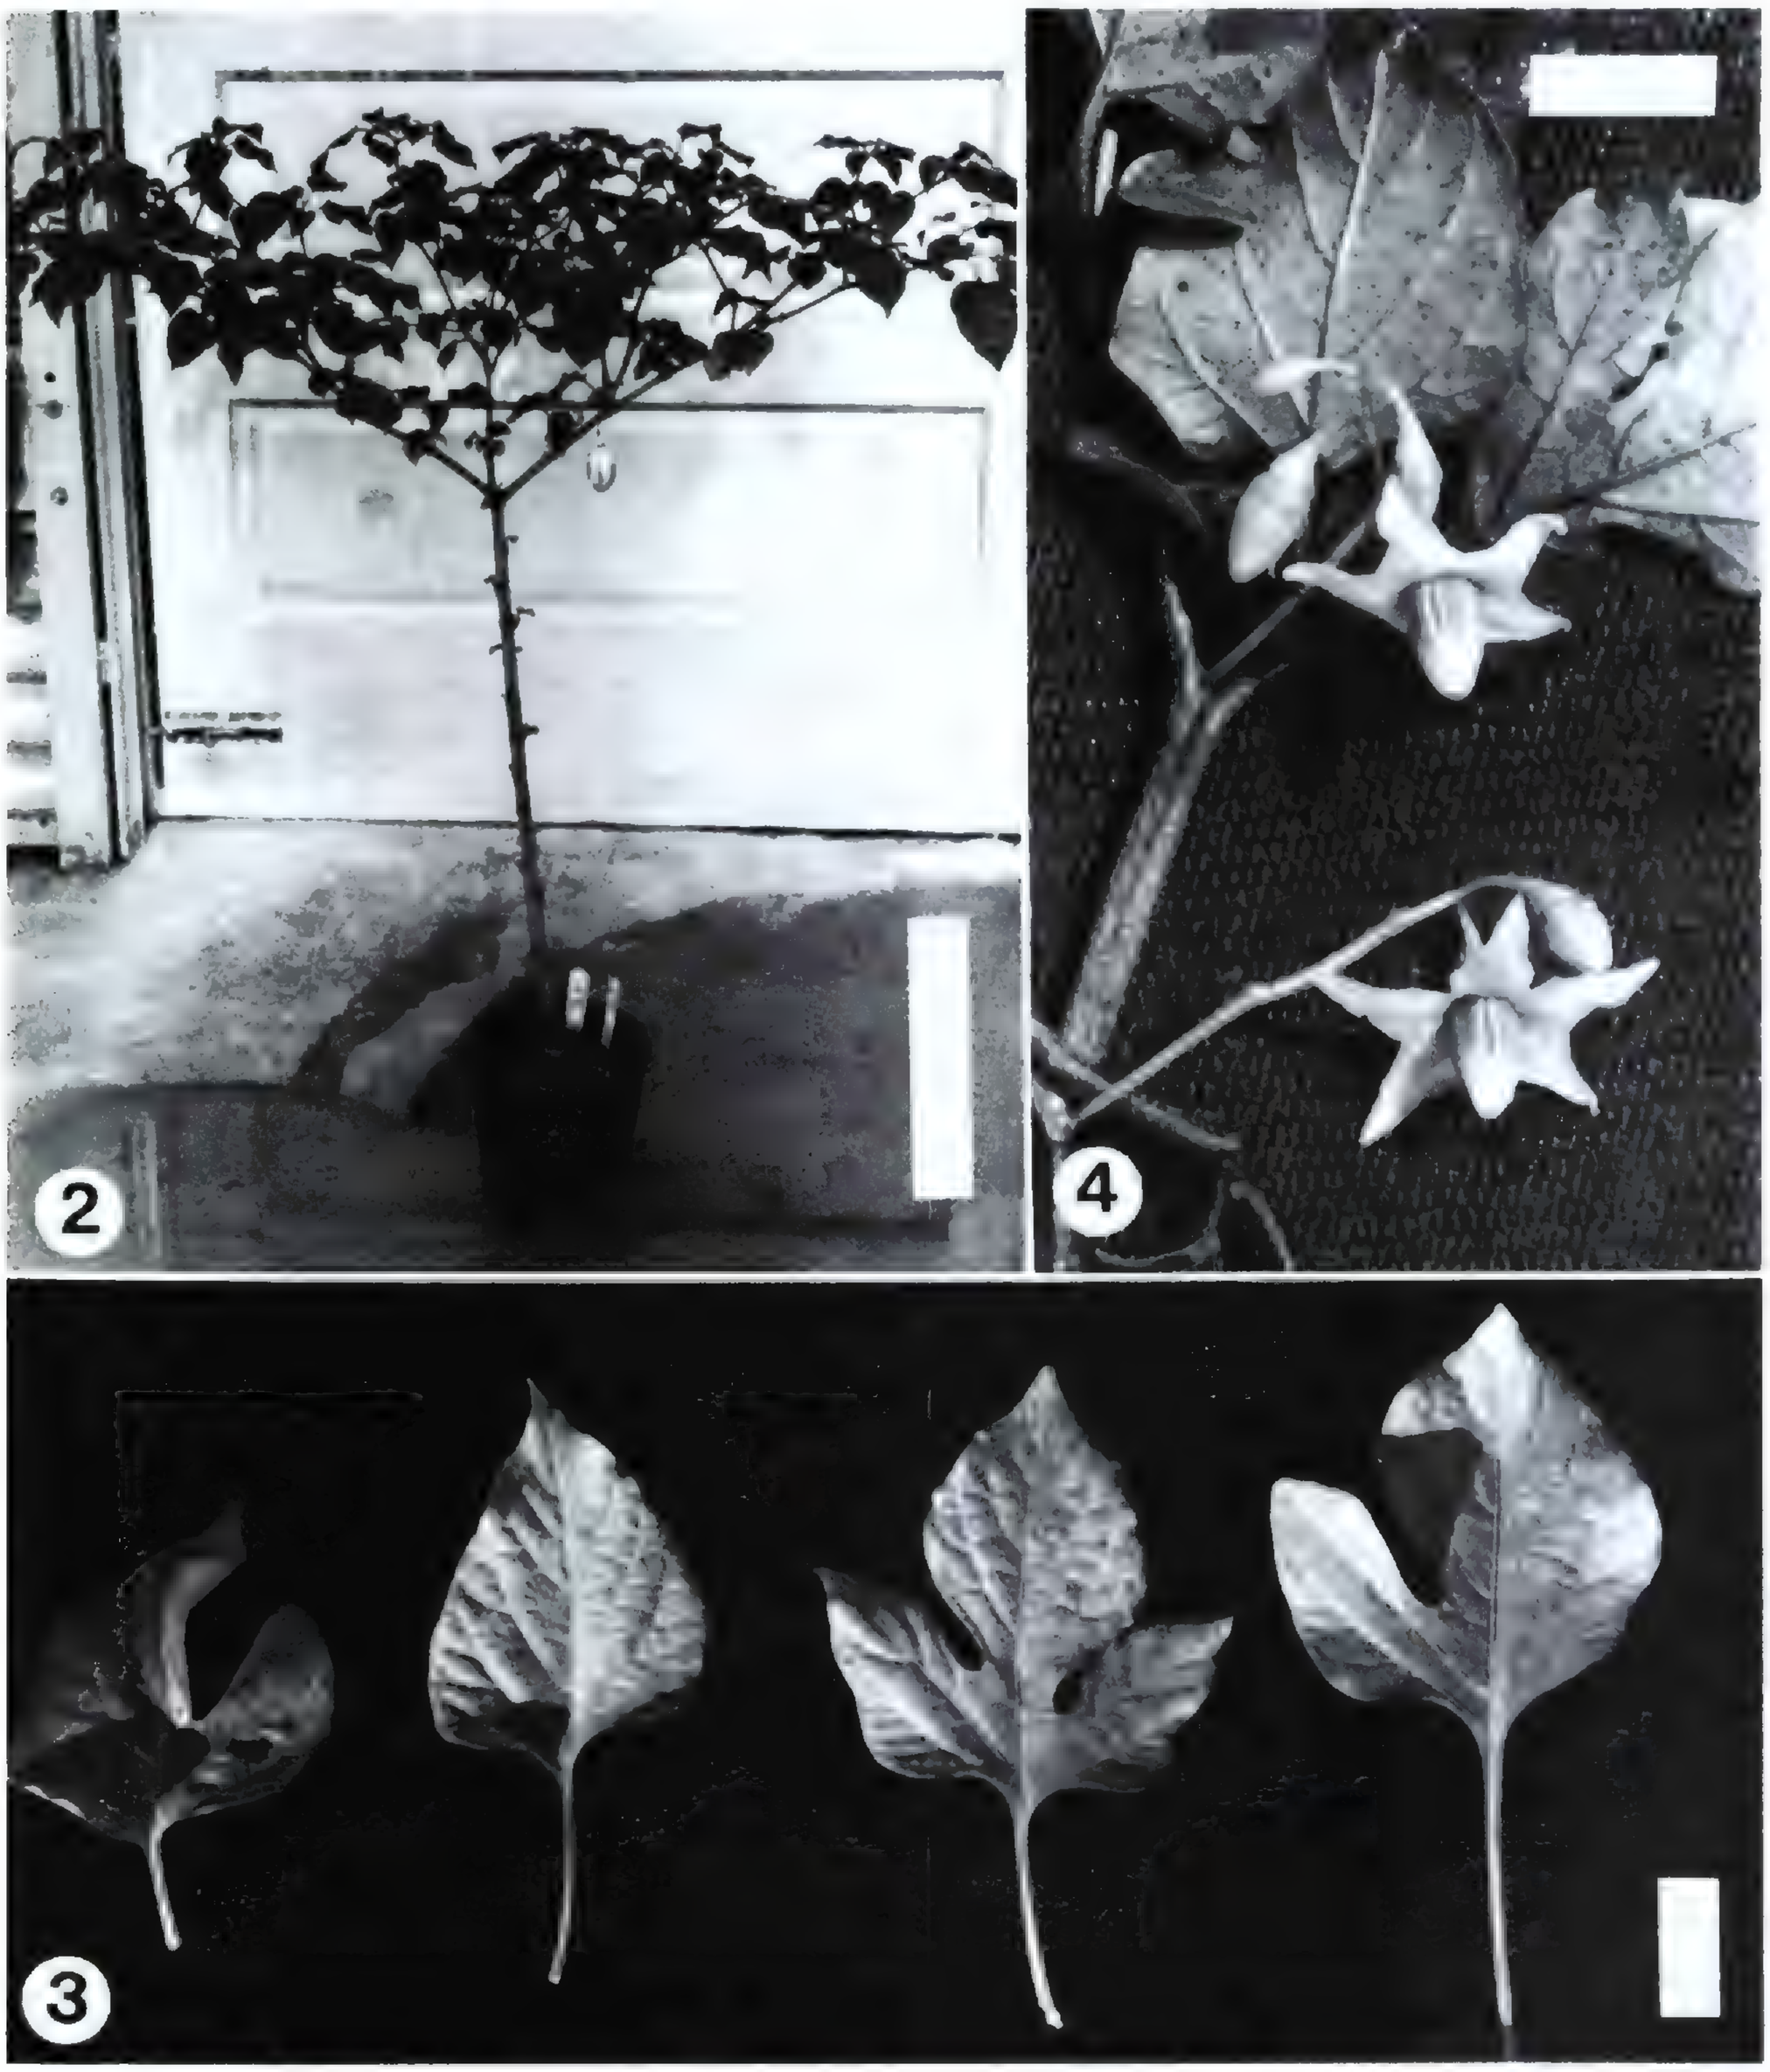
only fall after they are completely ripe. Their dispersal agents are unknown, but they may be attractive to birds or bats.

ARCHITECTURE

The distinctive growth habit or shape of *S. allophyllum* and many species of *Cyphomandra* is a conspicuous feature that allows the plants to be recognized easily in the field. In terms of architecture, however, *Cyphomandra* and *S. allophyllum* are similar only in the initial phase of their growth (Fig. 6). In both, the seedling axis produces a single orthotropic, or upright, trunk with the leaves spirally arranged in a 2/5 phyllotaxis. This trunk ends with the production of a terminal inflorescence. Usually three plagiotropic, or horizontal, shoots then elongate from axillary buds located just below the inflorescence to produce a spreading crown (Fig. 6A, D). Further branching within the crown occurs by sylleptic elongation of axillary shoots immediately below the successive terminal inflorescences; thus the crown is composed of a series of sympodial units where all the flowers and fruits are borne. Beyond this, *Cyphomandra* and *S. allophyllum* diverge in their architecture.

In *Cyphomandra*, after continued sympodial growth and numerous episodes of flowering and fruiting, the plagiotropic branches begin to senesce. A new trunk then arises proleptically from an axillary bud on the old trunk below the branch tier and continues orthotropic growth until another terminal inflorescence and branch tier is produced. In this way, the main axis is composed of successive sympodial trunk modules bearing spatially and temporally separated reproductive crowns (Fig. 6B, C). I have seen this architecture in at least six species of *Cyphomandra*, and it is probably widespread in the genus. In contrast to *Cyphomandra*, *S. allophyllum* does not produce successive trunk modules. The whole plant in *S. allophyllum* is therefore equivalent to a single structural unit of the *Cyphomandra* growth form.

The architecture of *Cyphomandra* described above occupies an intermediate position between Prevost's and Nozeran's models in the scheme of Hallé et al. (1978). Both models have an orthotropic sympodial trunk and tiered plagiotropic



FIGURES 2–4. *Solanum allophyllum*. —2. Greenhouse-grown plant. Scale bar = 0.25 m. —3. Leaves from trunk. Scale bar = 2 cm. —4. Flowers. Scale bar = 1 cm.

branches. In Prevost's model both the trunk and plagiotropic branches generally have spirally arranged leaves, whereas in Nozeran's model the orthotropic and plagiotropic branches have highly contrasting leaf arrangements, usually with spiral phyllotaxis on the trunk and distichous phyllotaxy on the branches. Plagiotropy of the branches in Nozeran's model is perpetuated if a crown branch is independently propagated, whereas in Prevost's model the plagiotropy of the crown branches is usually lost when they are separated from the trunk. The leaf arrangement of the crown branches in *Cyphomandra* is affected by pronounced twisting of the axes and differential elongation of branch internodes (see section on branching pattern below for a more detailed description of leaf arrangement, and Danert, 1958, 1967, for comparative morphology of the shoot systems in Solanaceae). Therefore, although the leaf arrangement on the plagiotropic shoots is not distichous, the crown branches show pronounced dorsiventral symmetry in contrast to the radial symmetry of the spirally arranged trunk leaves. Cuttings taken from the crown region of *C. betacea*, *C. diploconos*, and *C. diversifolia* produce lower, bushier plants than those taken from the upright axes (Fletcher, 1979; pers. obs.),

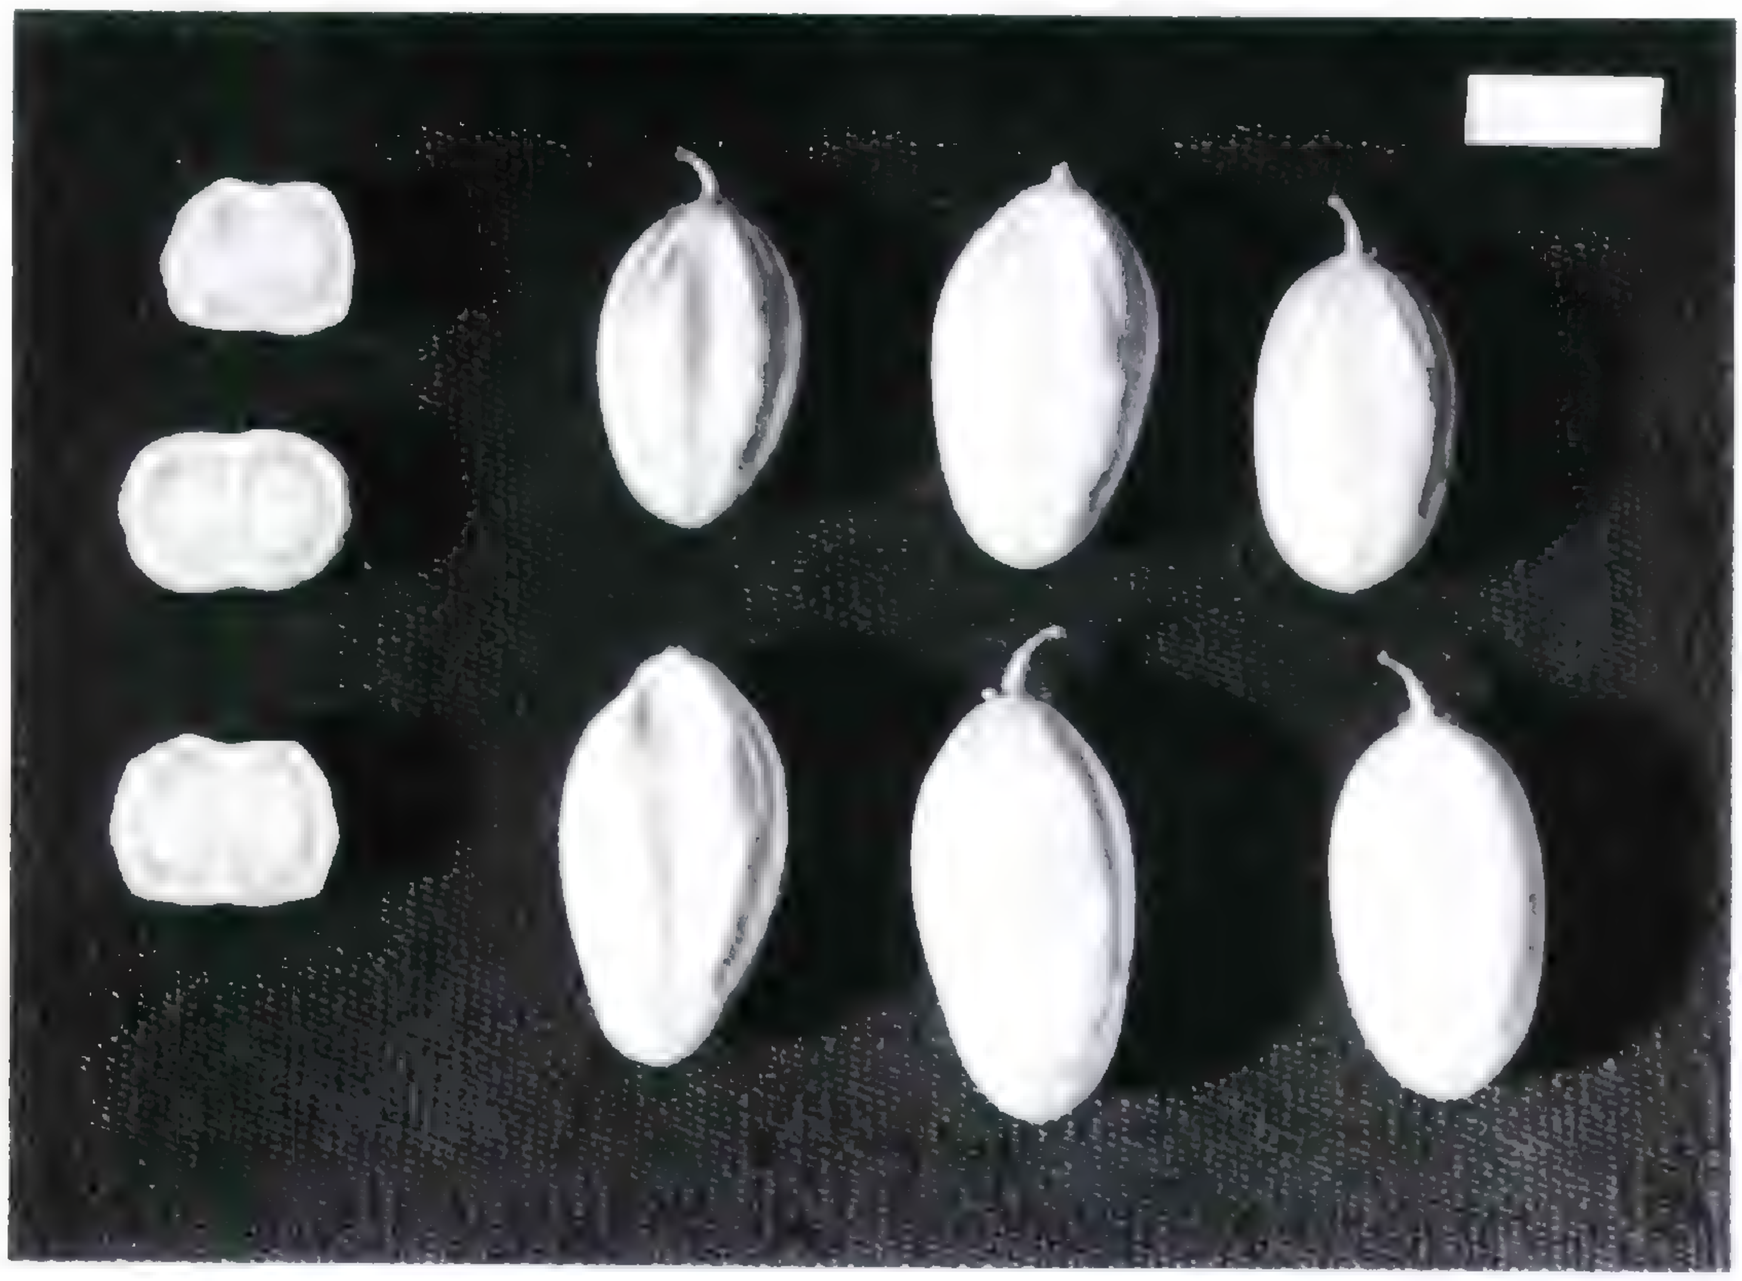


FIGURE 5. Fruits of *Solanum allophyllum*. Scale bar = 2 cm.

so these species apparently exhibit the inherent nature of plagiotropy in the crown branches characteristic of Nozeran's model. At least until an accurate interpretation of leaf arrangement on the plagiotropic shoots is available, it is probably best to consider *Cyphomandra* as being intermediate between Prevost's and Nozeran's model.

The architecture of *S. allophyllum* does not strictly conform to any of the models defined in Hallé et al. (1978). It most closely resembles Leeuwenberg's model, which is exhibited by several species of *Solanum* and *Capsicum* (Hallé et al., 1978). However, in Leeuwenberg's model, all the axes are orthotropic and equivalent, whereas in *S. allophyllum* there is evident differentiation between the trunk and crown branches. Perhaps the best way to characterize the architectural form of *S. allophyllum* is to consider that it may have been derived by "fragmentation" from more woody counterparts with multiple trunk modules, such as those seen in *Cyphomandra*. Fragmentation occurs when only a portion of the original tree model is expressed, and is commonly seen in herbaceous relatives of woody plants with more strongly developed trunk modules. Should it indeed be the case that the architectural form of *S. allophyllum* is related in this way to more extensive tree models, it may argue that this relatively herbaceous species has been derived by reduction and fragmentation from woody ancestors.

BRANCHING PATTERN

Three- to four-leaved sympodial units are the rule within the crown of nearly all species of *Cyphomandra* (Fig. 7); the only known exception is *C. corymbiflora*, which frequently has five-leaved sympodia. Three-leaved sympodial units are also characteristic of *S. allophyllum*. Commonly, the leaf subtending the renewal shoot is carried up to a point nearly opposite that of the first leaf produced on the axillary shoot so that the seemingly opposite leaves are actually members of successive sympodial shoot generations. In *S. allophyllum* and in many species of *Cyphomandra*, two renewal shoots grow out from below the terminal inflorescence, thus situating it in a branch fork. This shoot structure was previously thought to be peculiar to *Cyphomandra* (Bohs, 1986), and its presence in *S. allophyllum* was evidence supporting the inclusion of the species within *Cyphomandra*. Members of *Solanum* may have one- to many-leaved sympodial units, and the inflorescences may be axillary, extraaxillary, opposite a leaf or leaf cluster, or rarely in branch forks.

Subtle differences exist in leaf and shoot arrangement within the crown branches of *Cyphomandra* and *S. allophyllum* apart from the leaves and branches making up the sympodial shoot structure. In *S. allophyllum*, nearly all the axillary buds of the crown expand into short shoots, giving the

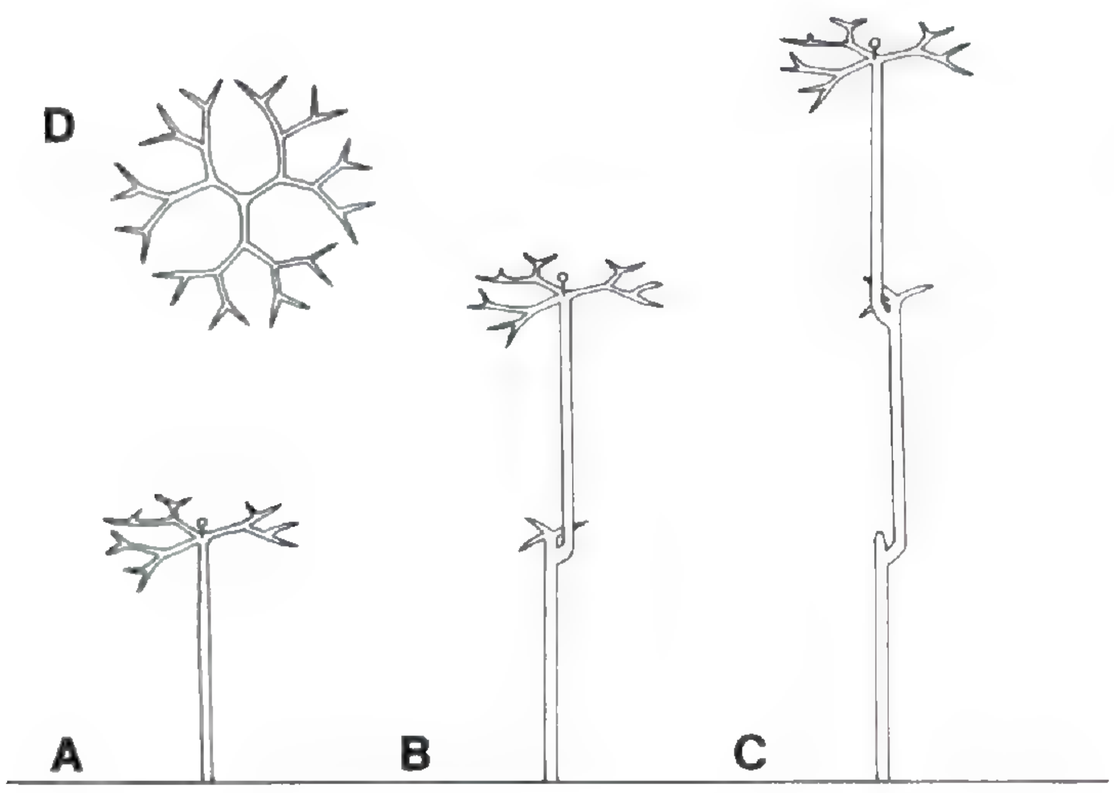

FIGURE 6. Architecture of *Cyphomandra* and *Solanum allophyllum*. —A, B, C. Successive growth stages in *Cyphomandra*, showing the sympodial nature of the trunk and the plagiotropic orientation of the crown branches. *Solanum allophyllum* does not develop beyond stage A. —D. Top view of crown, showing three main plagiotropic branches.

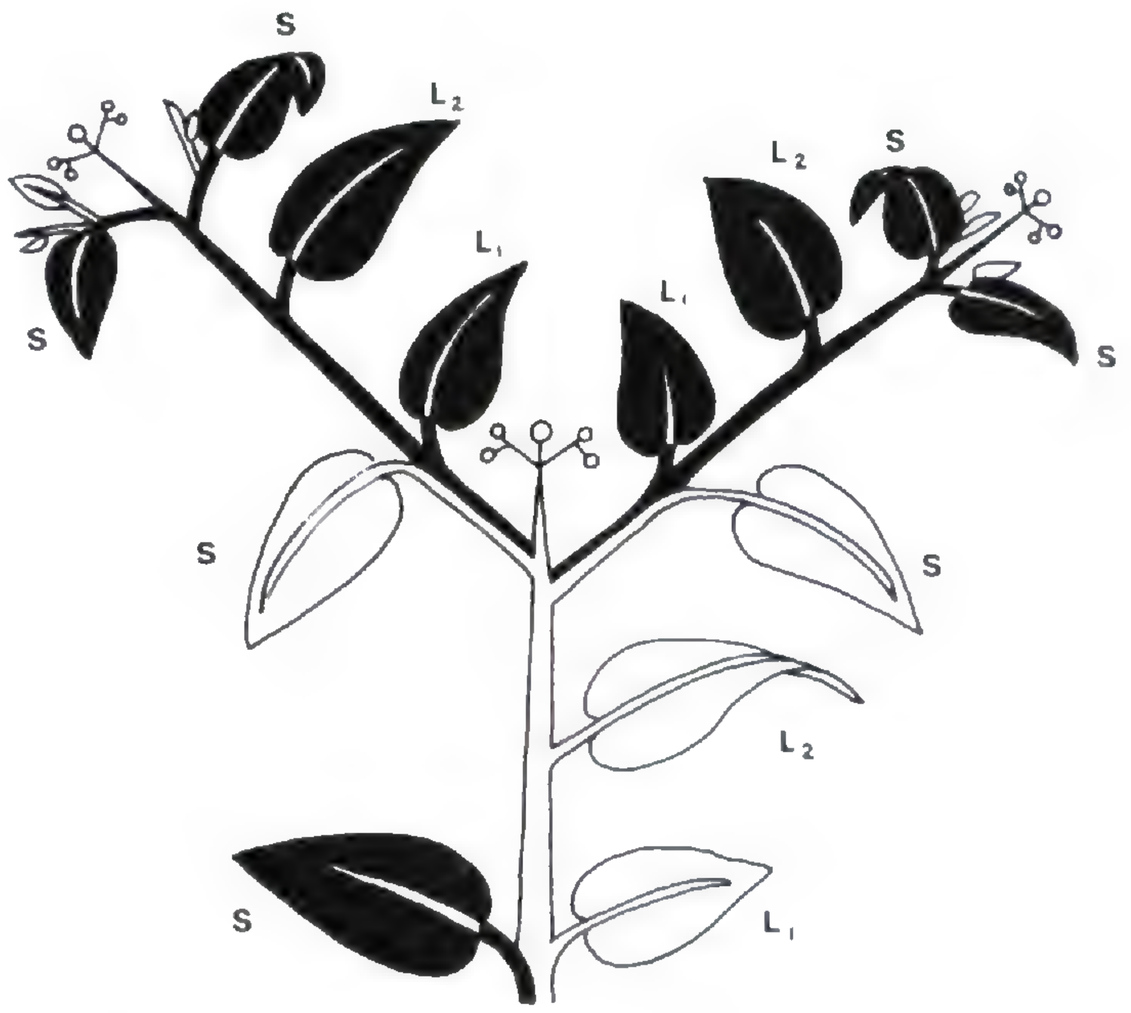

FIGURE 7. Diagram of branching pattern in the crown of *Cyphomandra* and *Solanum allophyllum*. Black and white shading denotes successive sympodial units. The subtending leaf (S) of the axillary shoot has been carried up to a level subopposite the first leaf on this shoot (L_1). The diagram shows a species with four-leaved sympodia; in three-leaved sympodia, the leaf L_2 is absent.

crown a dense leafy appearance. In *Cyphomandra*, sylleptic growth is restricted to the axillary buds immediately subtending the terminal inflorescences of the sympodial units, the rest of the buds remaining dormant unless released by pruning or breaking the tip of the branch. In the greenhouse, *S. allophyllum* also undergoes pronounced seasonal reiteration, with expansion of many buds on the trunk by prolepsis and elongation of the short shoots of the crown. It is not known whether *S. allophyllum* reiterates in this way under natural conditions; as already mentioned, it may die back to the main stem each year and produce a new plant conforming to the initial model at the beginning of the rainy season.

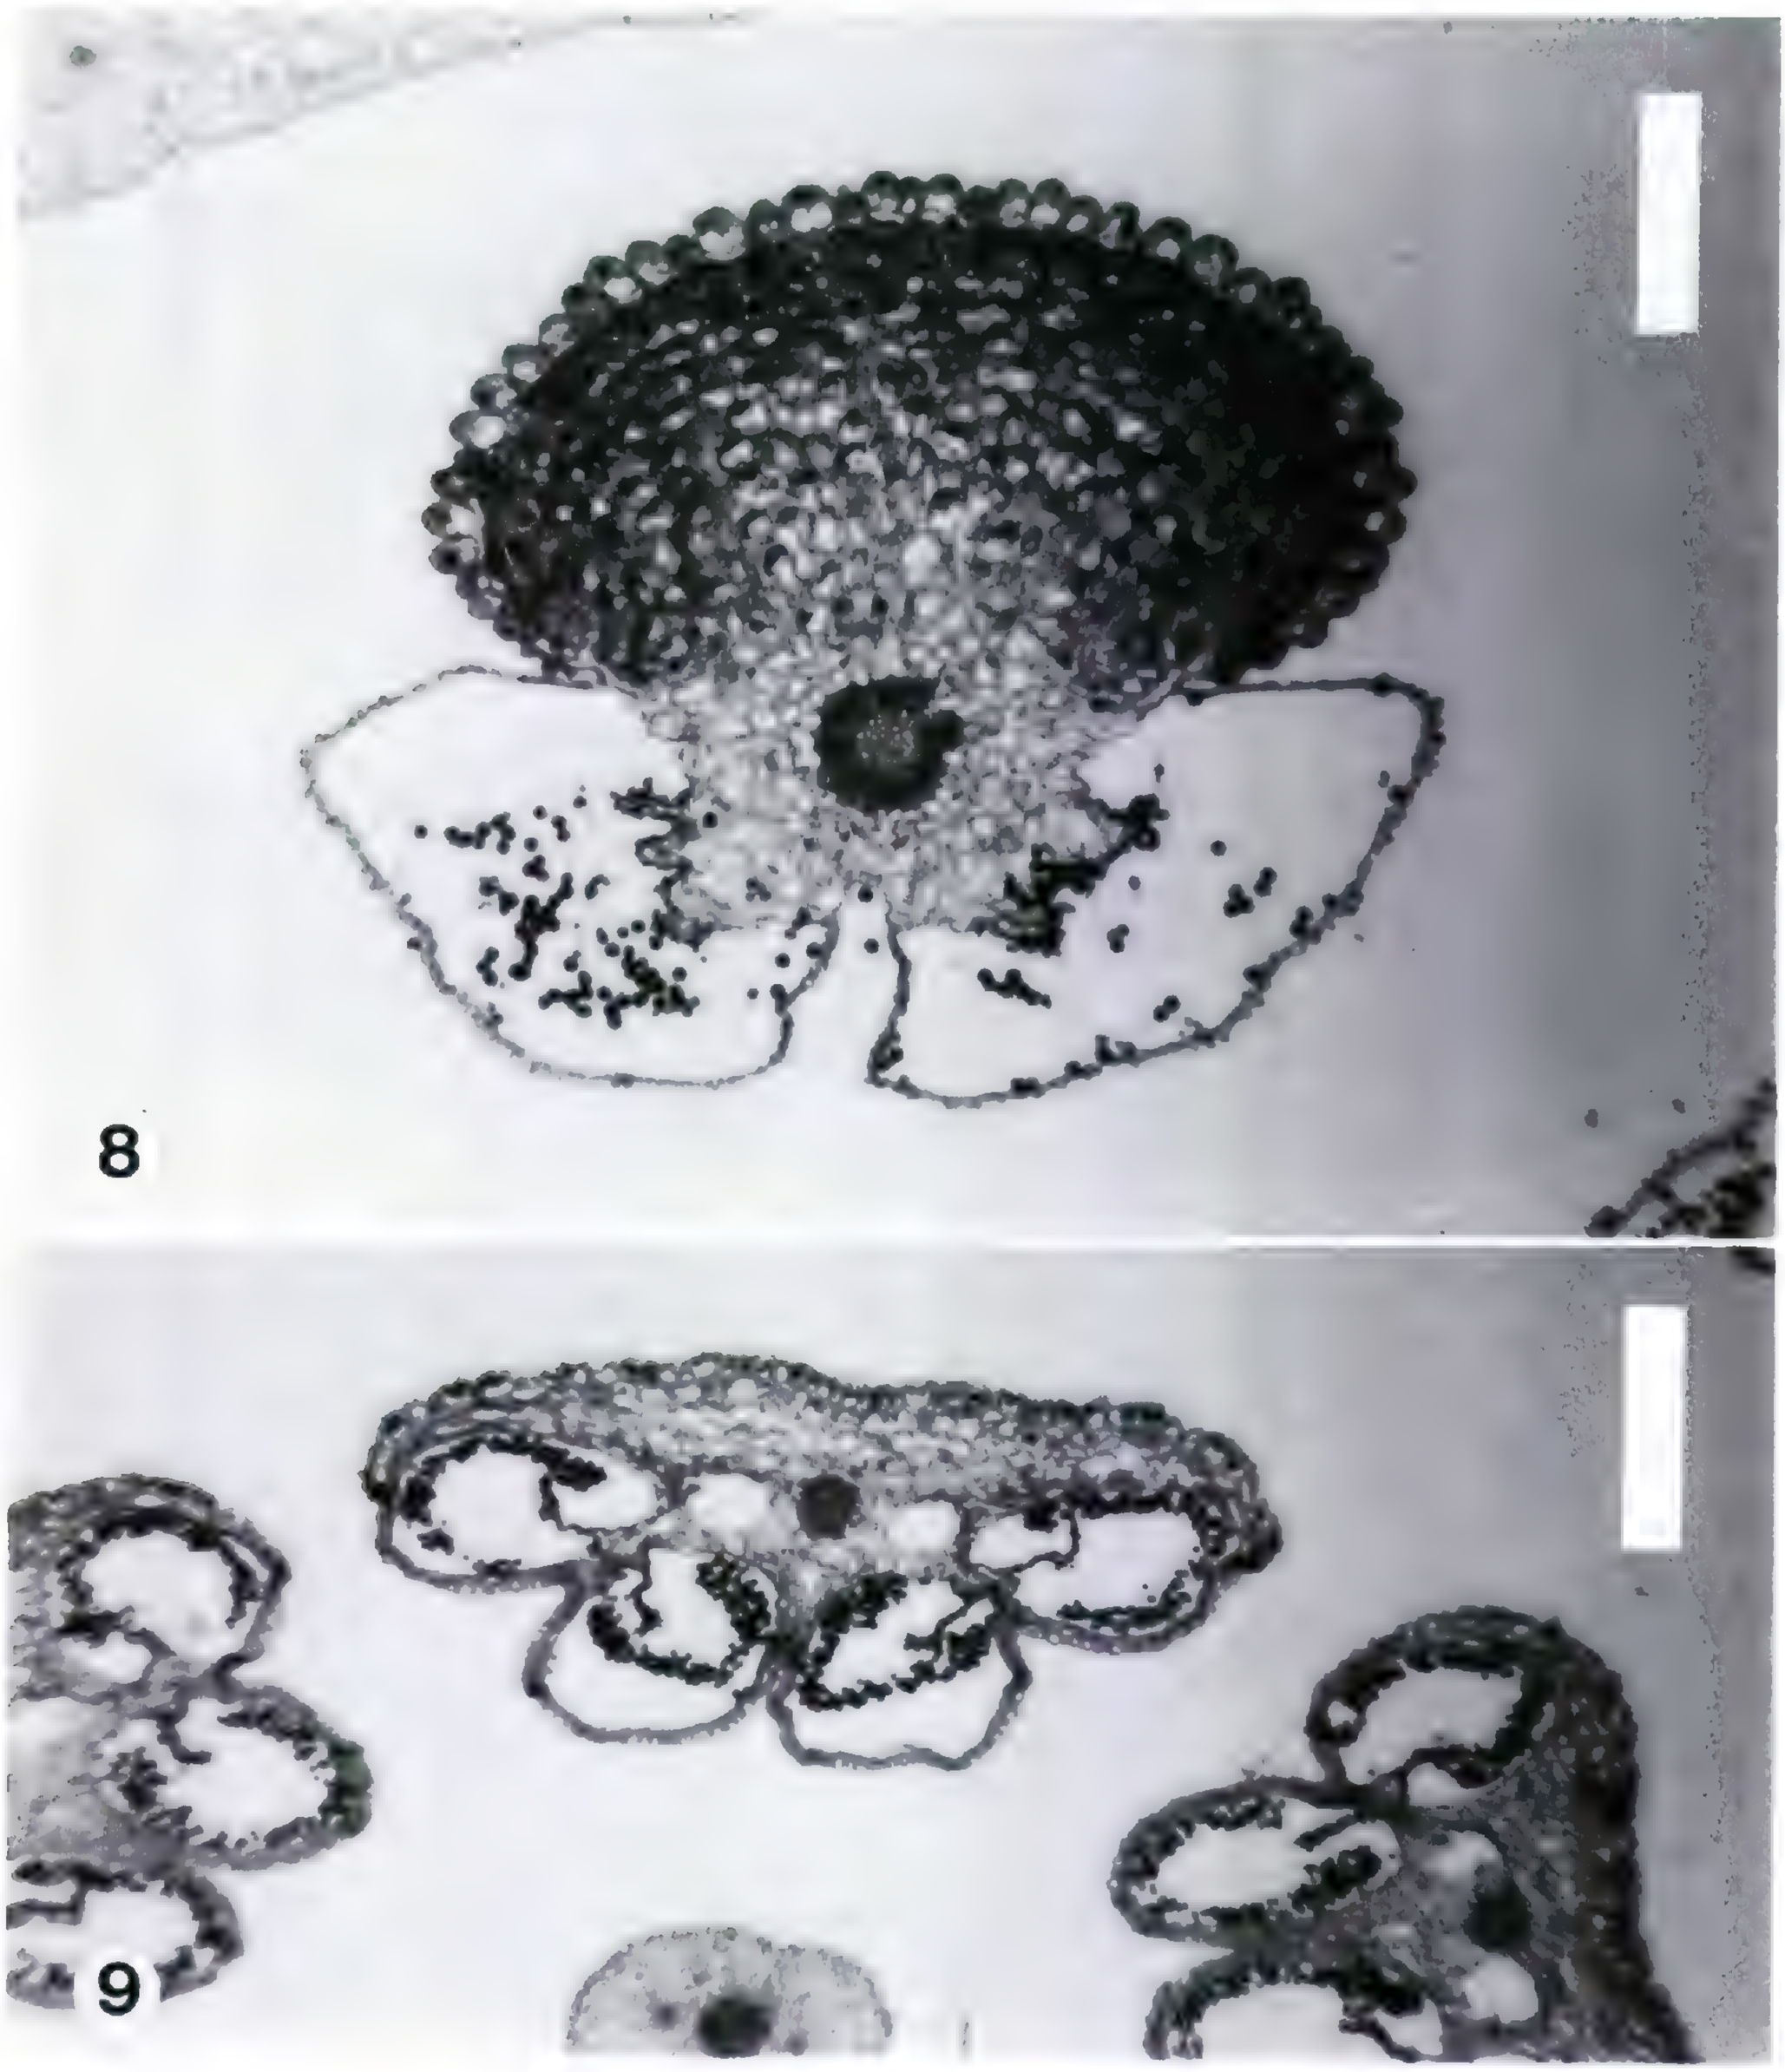
ANTHER MORPHOLOGY

Tapered anthers with an abaxial thickening occur in *Cyphomandra* and *S. allophyllum* (Figs. 8, 9). Anther shape is not a definitive characteristic of either genus, however; tapered anthers occur in other species of *Solanum* (e.g., in subg. *Leptostemonum* (Dun.) Bitt., subg. *Potatoe* (G. Don) D'Arcy, and sect. *Herposolanum* Bitt.), and although they are common in *Cyphomandra*, they are not exhibited in all of its species. There is no present evidence to indicate that tapered anthers are homologous within or among these groups. A more important criterion for distinguishing *Cyphomandra* from *Solanum* is found in the enlarged anther connective. In *Cyphomandra*, the anther connective is usually very thickened and prominent abaxially and is sharply delimited from the thinwalled anther thecae. Anthers of *Solanum* can be thickened in various ways, but they never have a distinct and abaxially prominent connective.

Solanum allophyllum has a thickened area on the abaxial side of the anther that has been interpreted as an enlarged connective like that of *Cyphomandra*, and has led to the inclusion of *S. allophyllum* within *Cyphomandra*. Microscopic cross sections through the anther region of *S. allophyllum* and a representative of *Cyphomandra*, *C. diversifolia* (Dun.) Bitt., show that anther structure is very different in the two taxa. In *Cyphomandra* (Fig. 8), the thickened portion is expanded

TABLE 2. Compatibility studies in *Cyphomandra* and *Solanum*.

	Selfed		Outcrossed	
Taxon	N	% Successful crosses	N	% Successful crosses
C. betacea	20	55%	36	36%
C. diversifolia	77	0%	152	6%
C. diploconos	108	0%	117	66%
C. hartwegii	38	0%	19	32%
C. uniloba	33	0%	11	55%
C. acuminata	60	0%	-	
C. corymbiflora	32	0%	30	93%
Solanum allophyllum	21	48%	52	31%



FIGURES 8, 9. Transverse sections through anthers.—8. *Cyphomandra diversifolia*.—9. *Solanum allophyllum*. Scale bars = 0.5 mm.

abaxially, the thecal walls are free and do not contribute to the thickening, and there is a sharp demarcation between the swollen connective and the thin-walled anther thecae. In contrast, the thickened area in *S. allophyllum* is not expanded abaxially and is contiguous with the walls of the anther thecae (Fig. 9). There is a gradual rather than abrupt transition from the thickened area on the abaxial surface to the thin-walled anther thecae. This type of anther structure conforms to that of many other species of *Solanum*. These differences are evident in transverse sections through fully mature anthers; similar studies on developing stages in these species may further emphasize these differences and may also reveal the derivation of the tissue involved in the anther thickening in both taxa.

COMPATIBILITY

Table 2 illustrates the results of controlled pollinations in the greenhouse of flowers of *S. allophyllum* and various species of *Cyphomandra*. The results show that of the seven species of *Cy-*

FIGURE 10. Camera lucida drawings of meiotic chromosomes in microsporangia.—A. *Cyphomandra diversifolia*.—B. *Solanum allophyllum*. A and B at same magnification.

phomandra tested, all are self-incompatible with the exception of the cultivated tree tomato, *C. betacea* (Cav.) Sendtn. In contrast, *S. allophyllum* appears to be self-compatible. Neither *S. allophyllum* nor *C. betacea* sets fruits in pollinator-free greenhouses without deliberate pollination. This indicates that these two species may not be autogamous and require a pollinator to transmit self pollen, or that they may be apomictic and pseudogamous. The style in *S. allophyllum* is not visible directly after anthesis, but elongates and emerges through the anther cone after the anthers dehisce. Thus, protandry may prevent selfing in this species.

CYTOLOGY

The most compelling evidence for the exclusion of *S. allophyllum* from *Cyphomandra* comes from chromosome studies. *Solanum allophyllum* and nine species of *Cyphomandra* that have been examined so far have $n = 12$ chromosomes (Bohs, unpublished data; Pringle & Murray, in press). This chromosome number is common in *Solanum* and the Solanaceae in general. However, chromosomes of the two taxa differ markedly in size (Figs. 10, 11). Investigations of seven species of *Cyphomandra* have revealed that the chromosomes in this genus are very large, averaging about 8 μm in length with a range of approximately 3 to 14 μm (Bohs, unpublished data). DNA amounts as measured by flow cytometry were among the largest yet known in the Solanaceae (Pringle & Murray, in press). In contrast, both the mitotic and meiotic chromosomes of *S. allophyllum* range between 1 and 2.5 μm in length and are thus on the order of 2.5 to 5.5 times smaller than those of *Cyphomandra*.

POLLEN

Pollen grains of *S. allophyllum* and *Cyphomandra* were examined for potential taxonomic characters. The grains of *S. allophyllum* are tricolporate and have exine sculpturing consisting of very small rounded granules best observed with SEM (Figs. 12–14). *Cyphomandra* pollen is also tricolporate, and most species have granular exine sculpturing like that of *S. allophyllum*, although several *Cyphomandra* species (e.g., *C. pendula* (R. & P.) Sendtn. and *C. pilosa* Bohs) lack such granules and have a psilate exine.

Although the aperture type and exine sculpturing show few taxonomically useful differences, the grains of *Cyphomandra* and *S. allophyllum* do differ somewhat in size and shape. Table 3 compares the pollen dimensions and volume of *S. allophyllum* and seven species of *Cyphomandra*. In the terminology of Erdtman (1952, 1969), all species of *Cyphomandra* have spheroidal or prolate spheroidal grains, whereas those of *S. allophyllum* are more elliptic in equatorial view and fall into the subprolate shape class. All taxa ex-

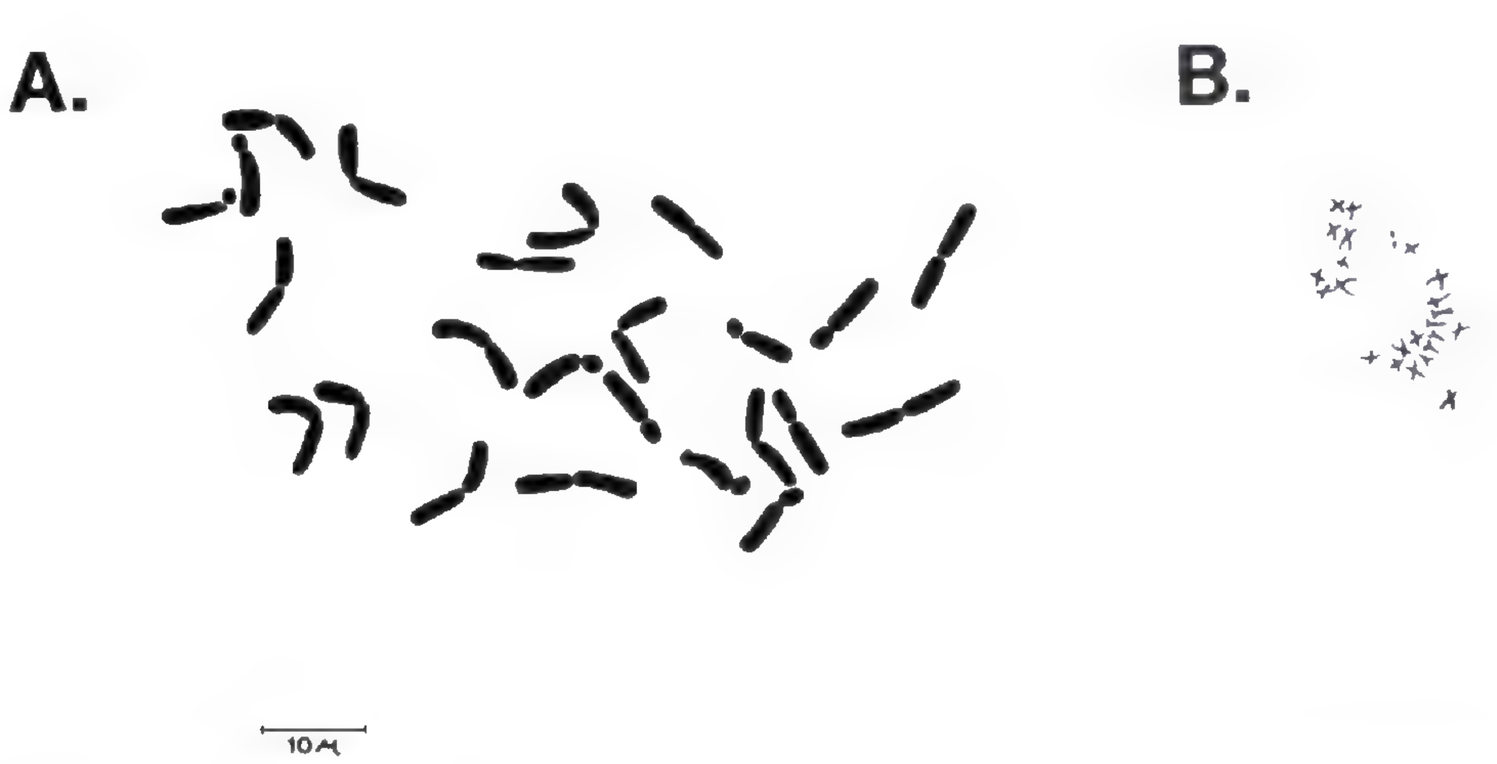


FIGURE 11. Camera lucida drawings of mitotic chromosomes in root tips.—A. *Cyphomandra acuminata*.—B. *Solanum allophyllum*. A and B at same magnification.

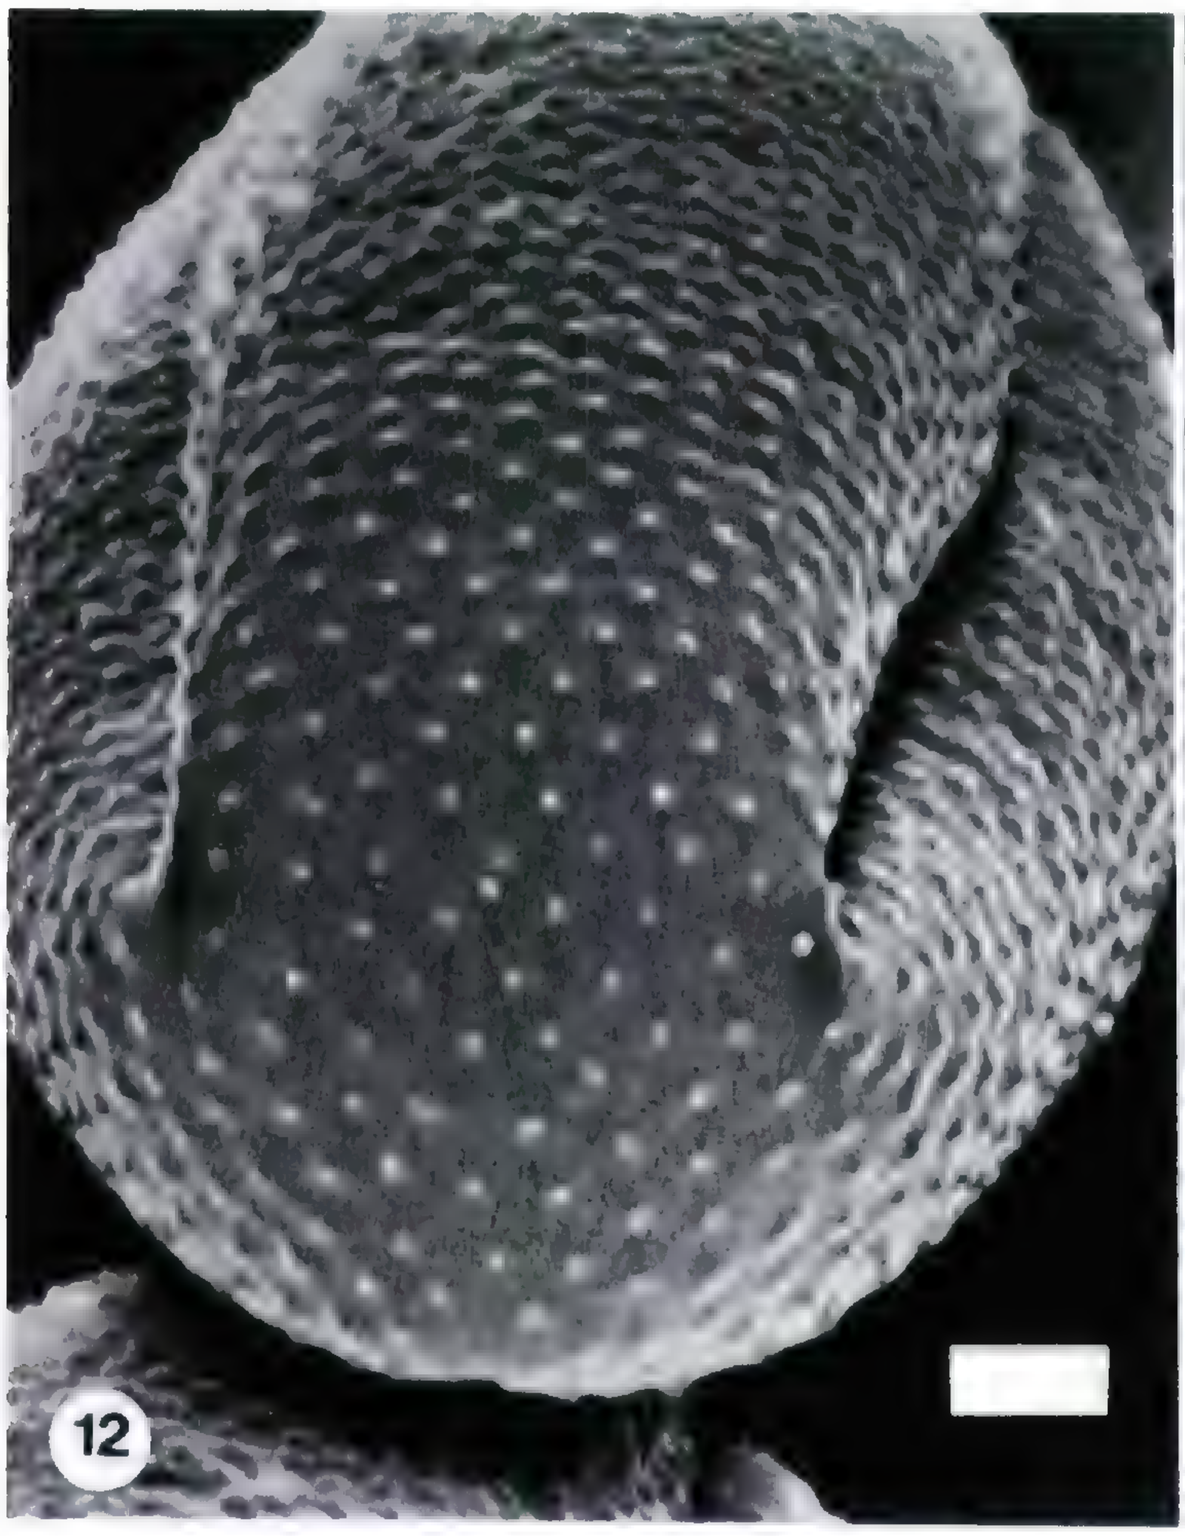

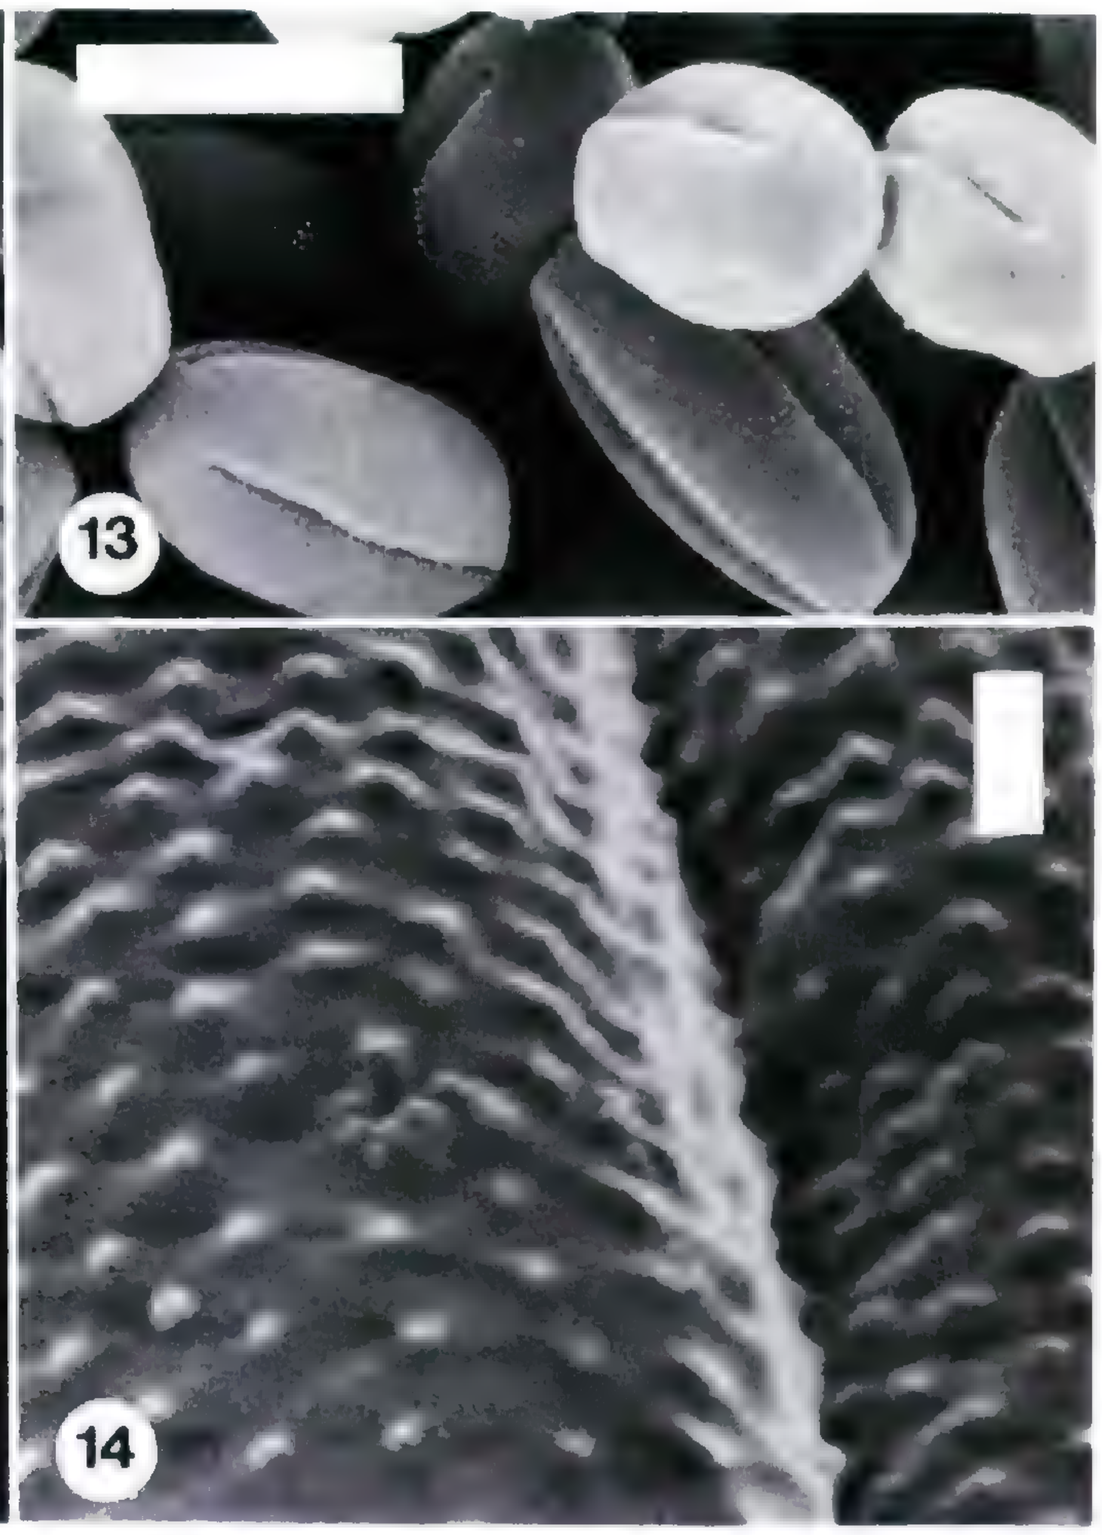

FIGURES 12–14. Pollen grains of *Solanum allophyllum*. — 12. Scale bar = 1 μm. — 13. Scale bar = 10 μm. 14. Scale bar = 0.5 μm.

amined have small- to medium-sized grains (again using Erdtman's terminology), but those of *S. allophyllum* are much smaller than any species of *Cyphomandra*. *Cyphomandra* grains have volumes about 2.5 to more than 10 times larger than those of *S. allophyllum*.

SEED SIZE

The seeds of *S. allophyllum* are substantially smaller than those of any of the *Cyphomandra* species examined (Table 3), ranging from about $\frac{1}{35}$ to $\frac{2}{5}$ the size of *Cyphomandra* seeds.

DISCUSSION

There are numerous differences in ecology, phenology, and morphology between *S. allophyllum* and *Cyphomandra*, but these alone do not permit an unequivocal placement of the species in either *Solanum* or *Cyphomandra*. Architecture and some aspects of the branching pattern further differentiate *S. allophyllum* from *Cyphomandra*, but again not enough to place the former definitively in either genus. A problem with the use of these characters is the wide range in architecture and branching pattern seen in *Solanum*. It looks as if these two characters cannot be as useful in distinguishing *Cyphomandra* and *Solanum* as was previously thought.

In contrast, a consideration of anther morphology shows that *S. allophyllum* does not have a distinct and enlarged anther connective like that of *Cyphomandra*. The anther structure formerly interpreted as a similarity between it and *Cyphomandra* is now revealed to be a difference that separates the two taxa. It appears that the presence of an enlarged anther connective is the most reliable morphological criterion for distinguishing *Cyphomandra* from *Solanum*.

The fact that *S. allophyllum* is self-compatible (SC), whereas the majority of *Cyphomandra* species are self-incompatible (SI), is at least an implication that *S. allophyllum* is not a *Cyphomandra*. Both SC and SI are known in *Solanum*, so the inclusion of *S. allophyllum* in *Solanum* is consistent on the basis of this character.

Self-compatibility in *C. betacea* could be an indication of its relatively recent origin. SC is considered to be a derived character in the Solanaceae (de Nettancourt, 1977; Whalen & Anderson, 1981). If this applies equally well to *Cyphomandra*, then the self-compatibility of the cultivated

TABLE 3. Pollen size and seed weight in *Cyphomandra* and *Solanum allophyllum*. Thirty grains/taxon measured for pollen size. Three measurements of 10 seeds averaged for seed weight. Standard deviations given in parentheses after measurements.

Taxon	Pollen polar diameter (μm)	Pollen equatorial diameter (μm)	Pollen volume (μm^3)	Seed weight (10 seeds) (g $\times 10^{-2}$)
C. diversifolia	33.66 (1.89)	31.92 (1.48)	18,068 (2,628)	3.97 (0.064)
C. uniloba	31.28 (1.63)	30.58 (1.42)	15,414 (2,182)	3.44 (0.276)
C. diploconos	29.24 (1.26)	27.73 (1.02)	12,043 (1,801)	1.84 (0.080)
C. acuminata	29.16 (1.09)	26.87 (0.92)	11,057 (1,108)	—
C. betacea	22.47 (1.21)	21.93 (0.76)	5,678 (637)	5.10 (0.127)
C. hartwegii	21.61 (0.96)	20.35 (0.95)	4,706 (587)	24.44 (0.706)
C. corymbiflora	21.45 (1.16)	19.97 (1.32)	4,520 (780)	4.03 (0.682)
S. allophyllum	16.54 (0.75)	14.21 (0.75)	1,756 (232)	0.70 (0.025)

C. betacea would be considered derived, perhaps in response to selection pressures relating to its domestication.

The small chromosomes of *S. allophyllum* conform to the size reported for species of *Solanum* from several different subgenera (Roe, 1967) and are the best indication that this species belongs in *Solanum*. The present study shows that there is a tendency toward large chromosomes in *Cyphomandra*. This appears to be a very useful character distinguishing *Cyphomandra* from *Solanum*. Further studies of chromosome size in the Solanaceae are needed to determine if this character is consistent in other species. Comparison of genome sizes between putatively primitive and derived members of many different plant groups demonstrates that changes in genome size can occur in either direction (Ohri & Khoshoo, 1986). Additional chromosome studies coupled with morphological data may eventually allow us to determine trends in the evolution of genome size in *Cyphomandra*, *Solanum*, and other solanaceous genera.

The exine sculpturing of *S. allophyllum* pollen also resembles that of *Solanum*. Anderson & Gensel (1976) and Edmonds (1984) reported similar granular exine sculpturing in *Solanum* sects. *Basarthrum* (Bitt.) Bitt. and *Solanum*, respectively. The occurrence of the same type of exine sculpturing in *Cyphomandra*, however, argues against the use of this character to distinguish *Cyphomandra* from *Solanum*. This same type of sculpturing also has been reported for other genera related to *Solanum* (Basak, 1967) and is probably the general pollen type of the tribe Solaneae.

The pollen grains and seeds of *S. allophyllum* are much smaller than those of any species of *Cyphomandra*. The pollen dimensions of *S. allophyllum* are comparable to some of the smaller grains reported for *Solanum* (Anderson & Gensel, 1976; Basak, 1967; Murry & Eshbaugh, 1971), and the size of the seeds falls within the range for *Solanum* (pers. obs.). Pollen or seed size has not been critically examined as a taxonomic character separating *Cyphomandra* and *Solanum*.

The small pollen and seeds of *S. allophyllum* may be connected with its small chromosome size. Bennett (1972) observed that genome size was correlated with pollen volume, seed weight, and minimum generation time in various species of herbaceous plants. The association of small chromosome size with small pollen volume, seed weight, and short generation time in *S. allophyllum* may indicate that this correlation also holds in this species. Further observations are needed to ascertain whether these characteristics are correlated in other solanaceous species, and whether pollen and seed size may be used as indicators of chromosome size.

Affinities of *S. allophyllum* within *Solanum* are problematic. This species is allied with two others, *S. mapiriense* Bitter from Bolivia and an undescribed species from Amazonian Peru (Bohs, in prep.). At present I know of no existing section of *Solanum* that accommodates these three species. They are perhaps best regarded as a new section of *Solanum*, as Bitter (1913) suggested. A taxonomic treatment of these three species and a consideration of their placement within *Solanum* will appear in a later paper.

Appendix. Voucher information.

Solanum allophyllum (Miers) Standley
Seed from *D'Arcy 9472*, collected in Panama, Prov. San Blas, in front of Ustupo. Vouchers: *Bohs 2339* (GH, VT).

Cyphomandra acuminata Rusby
Seed from *Solomon & Escobar 12458*, collected in Bolivia, Prov. Nor Yungas, 8.7 km below Chuspipata on road to Yolosa. Vouchers: *Bohs 2338* (GH, VT).

Cyphomandra betacea (Cav.) Sendtn.
Seed collected by C. Sperling in market, Quito, Ecuador. Vouchers: *Bohs 2274* (GH), *2275* (VT).

Cyphomandra corymbiflora Sendtn.
Seed collected in southeastern Brazil, sent by G. Pringle, D.S.I.R., New Zealand. Vouchers: *Bohs 2343* (GH, VT).

Cyphomandra diploconos (Mart.) Sendtn.
Seed collected in Brazil, Prov. Paraná, city of Curitiba. Vouchers: *Bohs 2335* (GH, VT).

Cyphomandra diversifolia (H. & B. ex Dunal) Bitter
Seed from *Benitez de Rojas 2744*, collected in Venezuela, Estado Aragua, Parque Nacional Henri Pittier. Vouchers: *Bohs 2341* (GH, VT).

Cyphomandra hartwegii (Miers) Sendtn. ex Walp.
Seed collected in Colombia, Dept. Huila, Fundación Merenberg. Voucher: *Bohs 1644* (GH).

Cyphomandra uniloba Rusby
Seed from *Sperling & King 5500*, collected in Bolivia, Prov. La Paz, Dept. Larecaja, between Consata and Mapiri. Vouchers: *Bohs 2283* (VT), *2284* (GH).

NOVELTIES IN SOUTH AMERICAN *MALOUETIA* (APOCYNACEAE)[1]

Mary E. Endress[2]

ABSTRACT

Three new species of *Malouetia* (*M. bubalina*, *M. molongo*, and *M. naias*) and one new variety (*M. pubescens* var. *glabra*) are described. All new taxa are from northwestern South America.

The following novelties have accumulated during studies of the genus *Malouetia*, for the most part in connection with the *Flora of the Venezuelan Guayana*.

1. **Malouetia bubalina** M. E. Endress, sp. nov. TYPE: Colombia. Amazonas: Río Caquetá, Monochoa, 25–30 km en amont de Araracuara, Sabana de Mosco, 30 Dec. 1976, *Sastre & Raichel 5062* (holotype, P). Figure 1.

Arbor lactescens. Folia decussata, lamina late elliptica vel obovata apice breviter et abrupte caudata 8–9.5 cm longa, 4–4.5 cm lata, basi anguste cuneata vel attenuata, coriacea vel subcoriacea, glabra, subtus ad nervorum axillas domatiis conspicuis instructa, nervis lateralibus ca. 6 utroque latere; petioli 3–5 mm longi. Inflorescentiae terminales e fasciculis 12–20-floris compositae. Calyx extus puberulus. Corolla flavida, hypocraterimorpha, tubo 6–6.5 mm longo; lobis ovatis acutis 6–7.5 mm longis, 2.5–3.5 mm latis utrinque dense puberulis; antherae basi faucis tubularis insertae sessiles fere ½ exsertae anguste lanceolatae dorso pilosae; ovarium dense pubescens. Folliculi 2 plus minusve crassi fusiformes 8–10 cm longi, 1 cm diametro versus medium fer 180° usque divergentes; semina 2 cm longa lineari-oblonga pilis longissimis retrorsis comatum basi obtusata.

Medium to large trees up to 30 m tall with abundant white latex; branches rather slender, angled and flattened at the nodes, with a glossy blackish sheen in the younger parts, becoming gray and conspicuously lenticellate with age. Leaves decussate, 8–9.5 cm long, 4–4.5 cm wide, the blades coriaceous to subcoriaceous, broadly elliptic to obovate-elliptic, shortly and bluntly acuminate at the apex, narrowly cuneate to attenuate at the base, the margins revolute, glabrous on both surfaces, the upper surface nitidulous, drying dark brown, the lower surface opaque, paler, with conspicuous domatia in the axils of the midvein; secondary veins ca. 6 on each side, arcuate-ascending, anastomosing before the margin, impressed on the upper surface, prominulent and darkened on the lower surface; tertiary veins inconspicuous on both surfaces; petioles 3–5 mm long, canaliculate, glabrous. Inflorescences 12–20-flowered, in terminal clusters; peduncle 1–2 mm long, glabrous, blackened, glossy; bracteoles ca. 1 mm long, broadly ovate, acute, coriaceous, subglabrous to sparsely puberulent outside, glabrous inside. Flowers pedicellate, pedicels 4–6 mm long, glabrous; calyx 2 mm diam., puberulent on the outer surface, glabrous on the inner surface with 5 small, flattened glands near the base alternating with the lobes, the lobes ca. 1.8 mm long, ovate, tapering to a rather blunt apex, the margins minutely ciliolate; corolla salverform, yellowish, glabrous on both surfaces, the tube proper 4.5–5 mm long, 1–1.3 mm diam., cylindrical, the upper cupular part 1.5 mm long, 1.5 mm diam., the orifice constricted by 5 rudimentary coronal scales, emphasizing the 5 nectar channels, the lobes 6–7 mm long, 2.5–3.5 mm wide, ovate, acute, densely puberulent on both surfaces; anthers inserted at the base of the cupular part of the corolla tube, about ½ exserted, sessile, narrowly lanceolate, sagittate, 2 mm long, dorsally barbellate in the upper half, the side wings glabrous, acuminate, incurving at the base; ovary ovoid, apocarpous, bilocular, ca. 0.5 mm high, densely pubescent, surrounded at the base by a glabrous, regularly 5-lobed disc nectary. Fruit apocarpous, glabrous, brown-black, composed of 2 stout, thick-walled, woody, fusiform follicles, 8–10 cm long, 1 cm diam. at the broadest point, diverging at ca.

[1] I thank Rupert Barneby and Peter Endress for help with the Latin descriptions, and the curators of the herbaria that lent specimens for study.

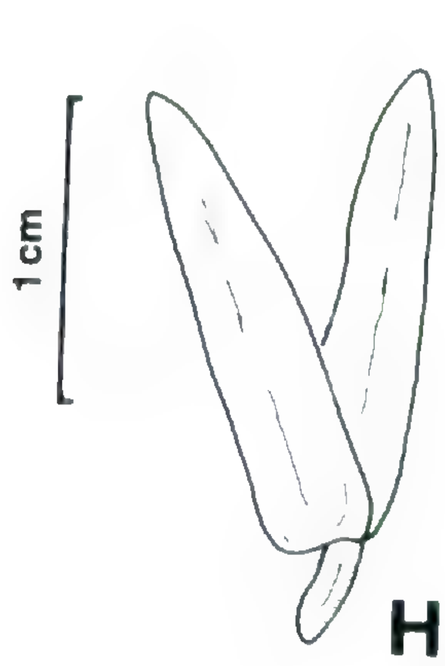

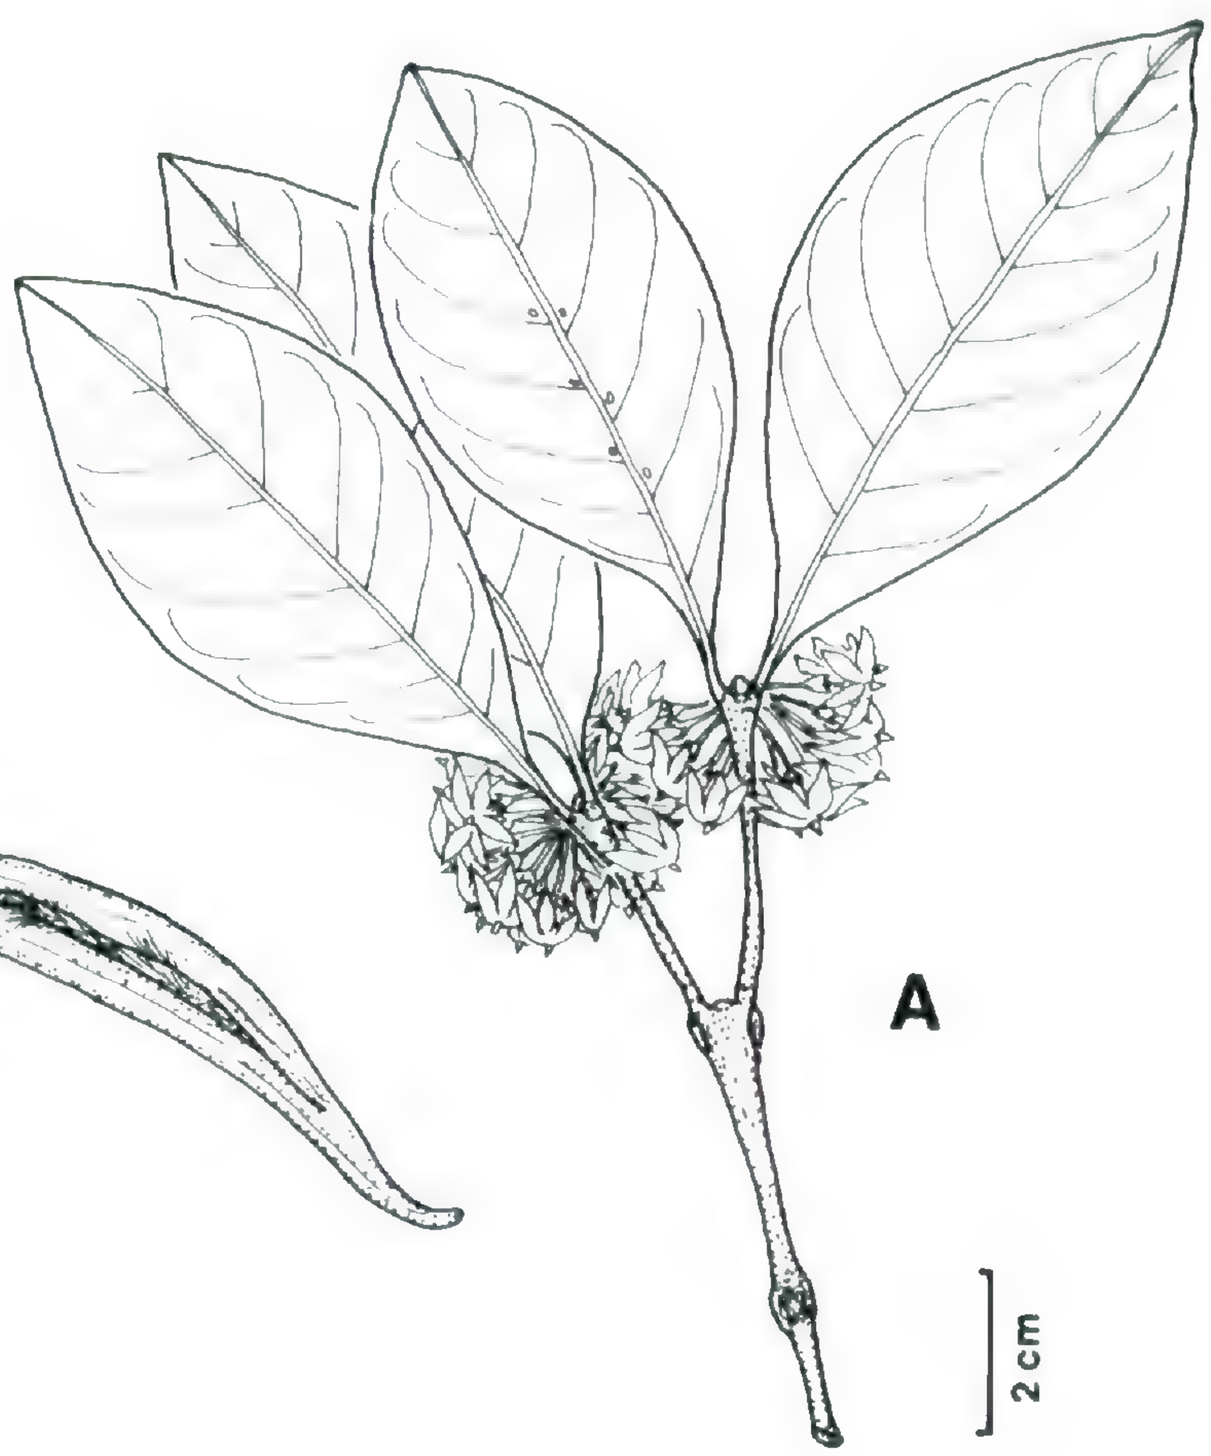

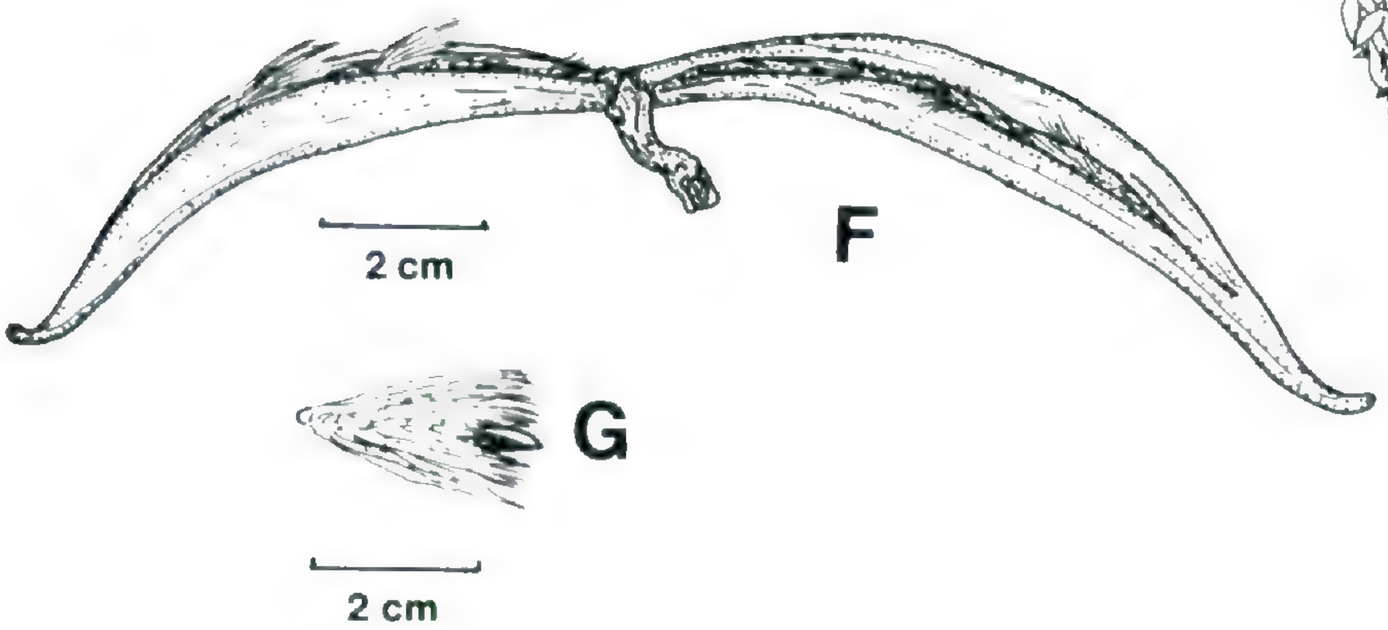

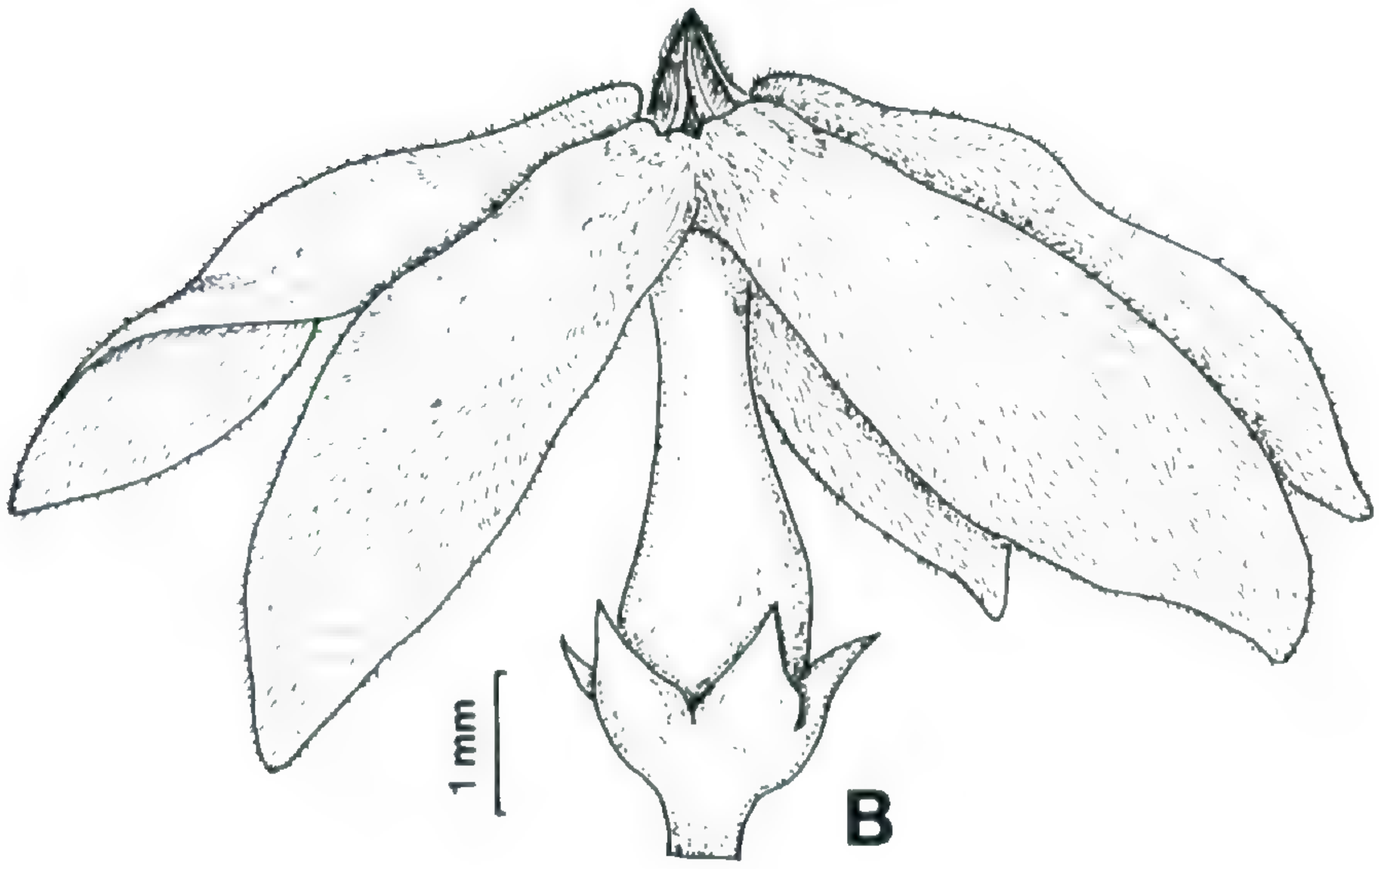

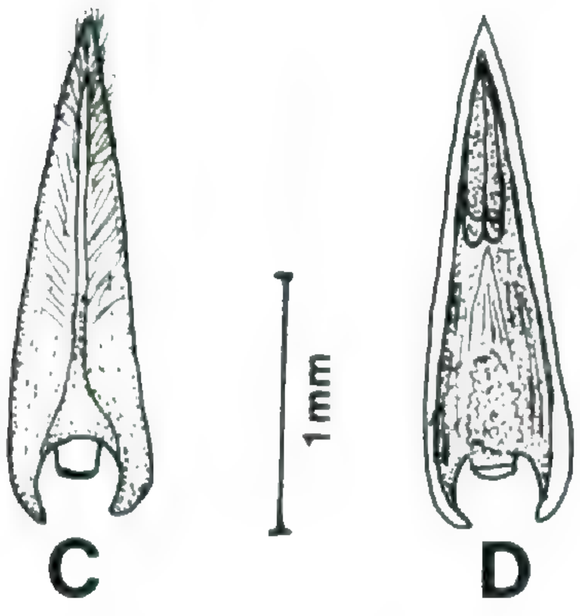

FIGURE 1. *Malouetia bubalina*.—A. Habit.—B. Flower.—C. Anther, dorsal view.—D. Anther, ventral view.—E. Embryo.—F. Fruit.—G. Seed.—H. Embryo. Based on the holotype.

180° then curving downward; seeds 2 cm long, slender, fusiform, laterally flattened, slightly convex on one side, the ventral surface longitudinally sulcate, the apical end (i.e., toward the fruit apex) abruptly converging into a rounded tip 1 mm long, proximally tapering to a rather blunt end, the apical tip embedded in a dense mat of long tan hairs, these attached to the apical half of the seed and directed toward the base of the follicle. Beneath the hairs the testa very thin, stiffly papery, smooth, glossy, yellowish tan, longitudinally striate; the endosperm forming a leathery case around the embryo; embryo 1.8 cm long, straight, the cotyledons rather fleshly, ca. 3½ times as long as the radicle, this thick, bent slightly.

Distribution. Colombia, known only from high forest over white sand at the type locality on the Río Caquetá.

The specific epithet refers to the bifid, stout, curving fruit reminiscent of buffalo horns.

Malouetia bubalina is most closely related to *M. arborea* (Vell.) Miers of eastern coastal Brazil, which also has stout fruits and seeds with an indumentum. But whereas the hairs on the seeds of *M. arborea* (Vell.) Miers are woolly and extend in all directions, those of *M. bubalina* are straight and directed toward the base of the follicle. The new species also differs by having much shorter pedicels and more ovate corolla lobes.

2. Malouetia molongo M. E. Endress, sp. nov. TYPE: Venezuela. T.F. Amazonas: Santa Cruz, margen del Río Atabapo, cerca del boca del Río Atacavi, *Foldats 3653* (holotype, NY). Figure 2.

Frutex vel arbuscula lactescens usque 2 m alta. Folia opposita obovata vel elliptica 4.5–7.5 cm longa, 1.5–2.5 cm lata, opaca subtus pallidiora margine revoluta nervis lateralibus 5 7 utroque latere; petioli 2–5 mm longi. Inflorescentiae terminales et axillares e fasciculis 2–3-floris compositae; calyx 2 mm longus, extus glaber; corolla alba hypocraterimorpha tubo 15.5–17 mm longo, lobis ovatis obtusis 8–9 mm longis, 4–5 mm latis, extus glabris intus prope basin granulato-papillatis; antherae inclusae paullo supra medium corollae tubum insertae; ovarium glabrum; ovula in utroque carpello ca. 12 3–4-seriatim affixa. Fructus ignoti.

Shrubs or small trees up to 2 m tall with white latex; branches blackish, glossy and angled in the younger parts, becoming terete and grayish with age. Leaves opposite, 4.5–7.5 cm long, 1.5–2.5 cm wide, the blades coriaceous, obovate to elliptic, obtuse to rounded at the apex, cuneate at the base, the margins revolute, glabrous on both surfaces, opaque, slightly paler on the lower surface, domatia absent; secondary veins 5–7 on each side, arcuate-ascending, anastomosing before the margin, obscure on both surfaces; tertiary venation inconspicuous on both surfaces; petioles 2–5 mm long, glabrous. Inflorescences 2–3-flowered, in terminal and axillary clusters; peduncle 1–2 mm long, glabrous; bracteoles broadly triangular, glabrous, ca. 1 mm long. Flowers pedicellate, pedicels 5–10 mm long, glabrous; calyx 2 mm long, 2–2.5 mm diam., glabrous without, glabrous within with pale, rather irregularly shaped toothlike glands alternating with the lobes, the lobes 1.5–2 mm long, glabrous, fleshy; corolla salverform, white, the tube 13–14 mm long, the upper cupular part 2.5–3 mm diam., glabrous without, glabrous within except for a short region of pilose hairs directly below the anthers and in the cupular part near the orifice, the orifice constricted by 5 weltlike rudimentary coronal scales, the lobes 8–9 mm long, 4–5 mm wide, ovate, obtuse at the apex, the outer surface glabrous, the inner surface papillose-puberulent and becoming more densely puberulent at the base; anthers inserted somewhat above midway in the corolla tube, completely included, 3 mm long, oblong, apiculate at the apex, the dorsal side glabrous, the side wings straight, the bases short and blunt; style-head cylindrical; ovary ovoid, apocarpous, bilocular, ca. 0.8 mm high, glabrous, surrounded at the base by a low, glabrous, 5-lobed disc nectary, the lobes truncate at the apex, basally connate for more than ½ their length; ovules ca. 12 per carpel, arranged in 3–4 rows. Fruit unknown.

Paratype. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Santa Cruz, margen del Río Atabapo, cerca del boca del Río Atacavi, *Foldats 3654* (NY, VEN).

Distribution. Known only from the type locality in Amazonian Venezuela near the confluence of the Río Atacavi with the Río Atabapo, on flooded river banks.

The name comes from *molongó* a frequent local name for various Apocynaceae of inundated habitats.

This species most closely resembles *Malouetia gracilis* (Benth.) A. DC. from Guyana but differs by having five cleft weltlike scales constricting the mouth of the corolla tube. In *M. gracilis* (Benth.) A. DC. coronal scales are lacking.

3. Malouetia naias M. E. Endress, sp. nov. TYPE: Colombia. Vaupés: Mitú and vicinity, along Río Vaupés between Río Yí and Río Kubiyú, inundated margin of river, 9 July

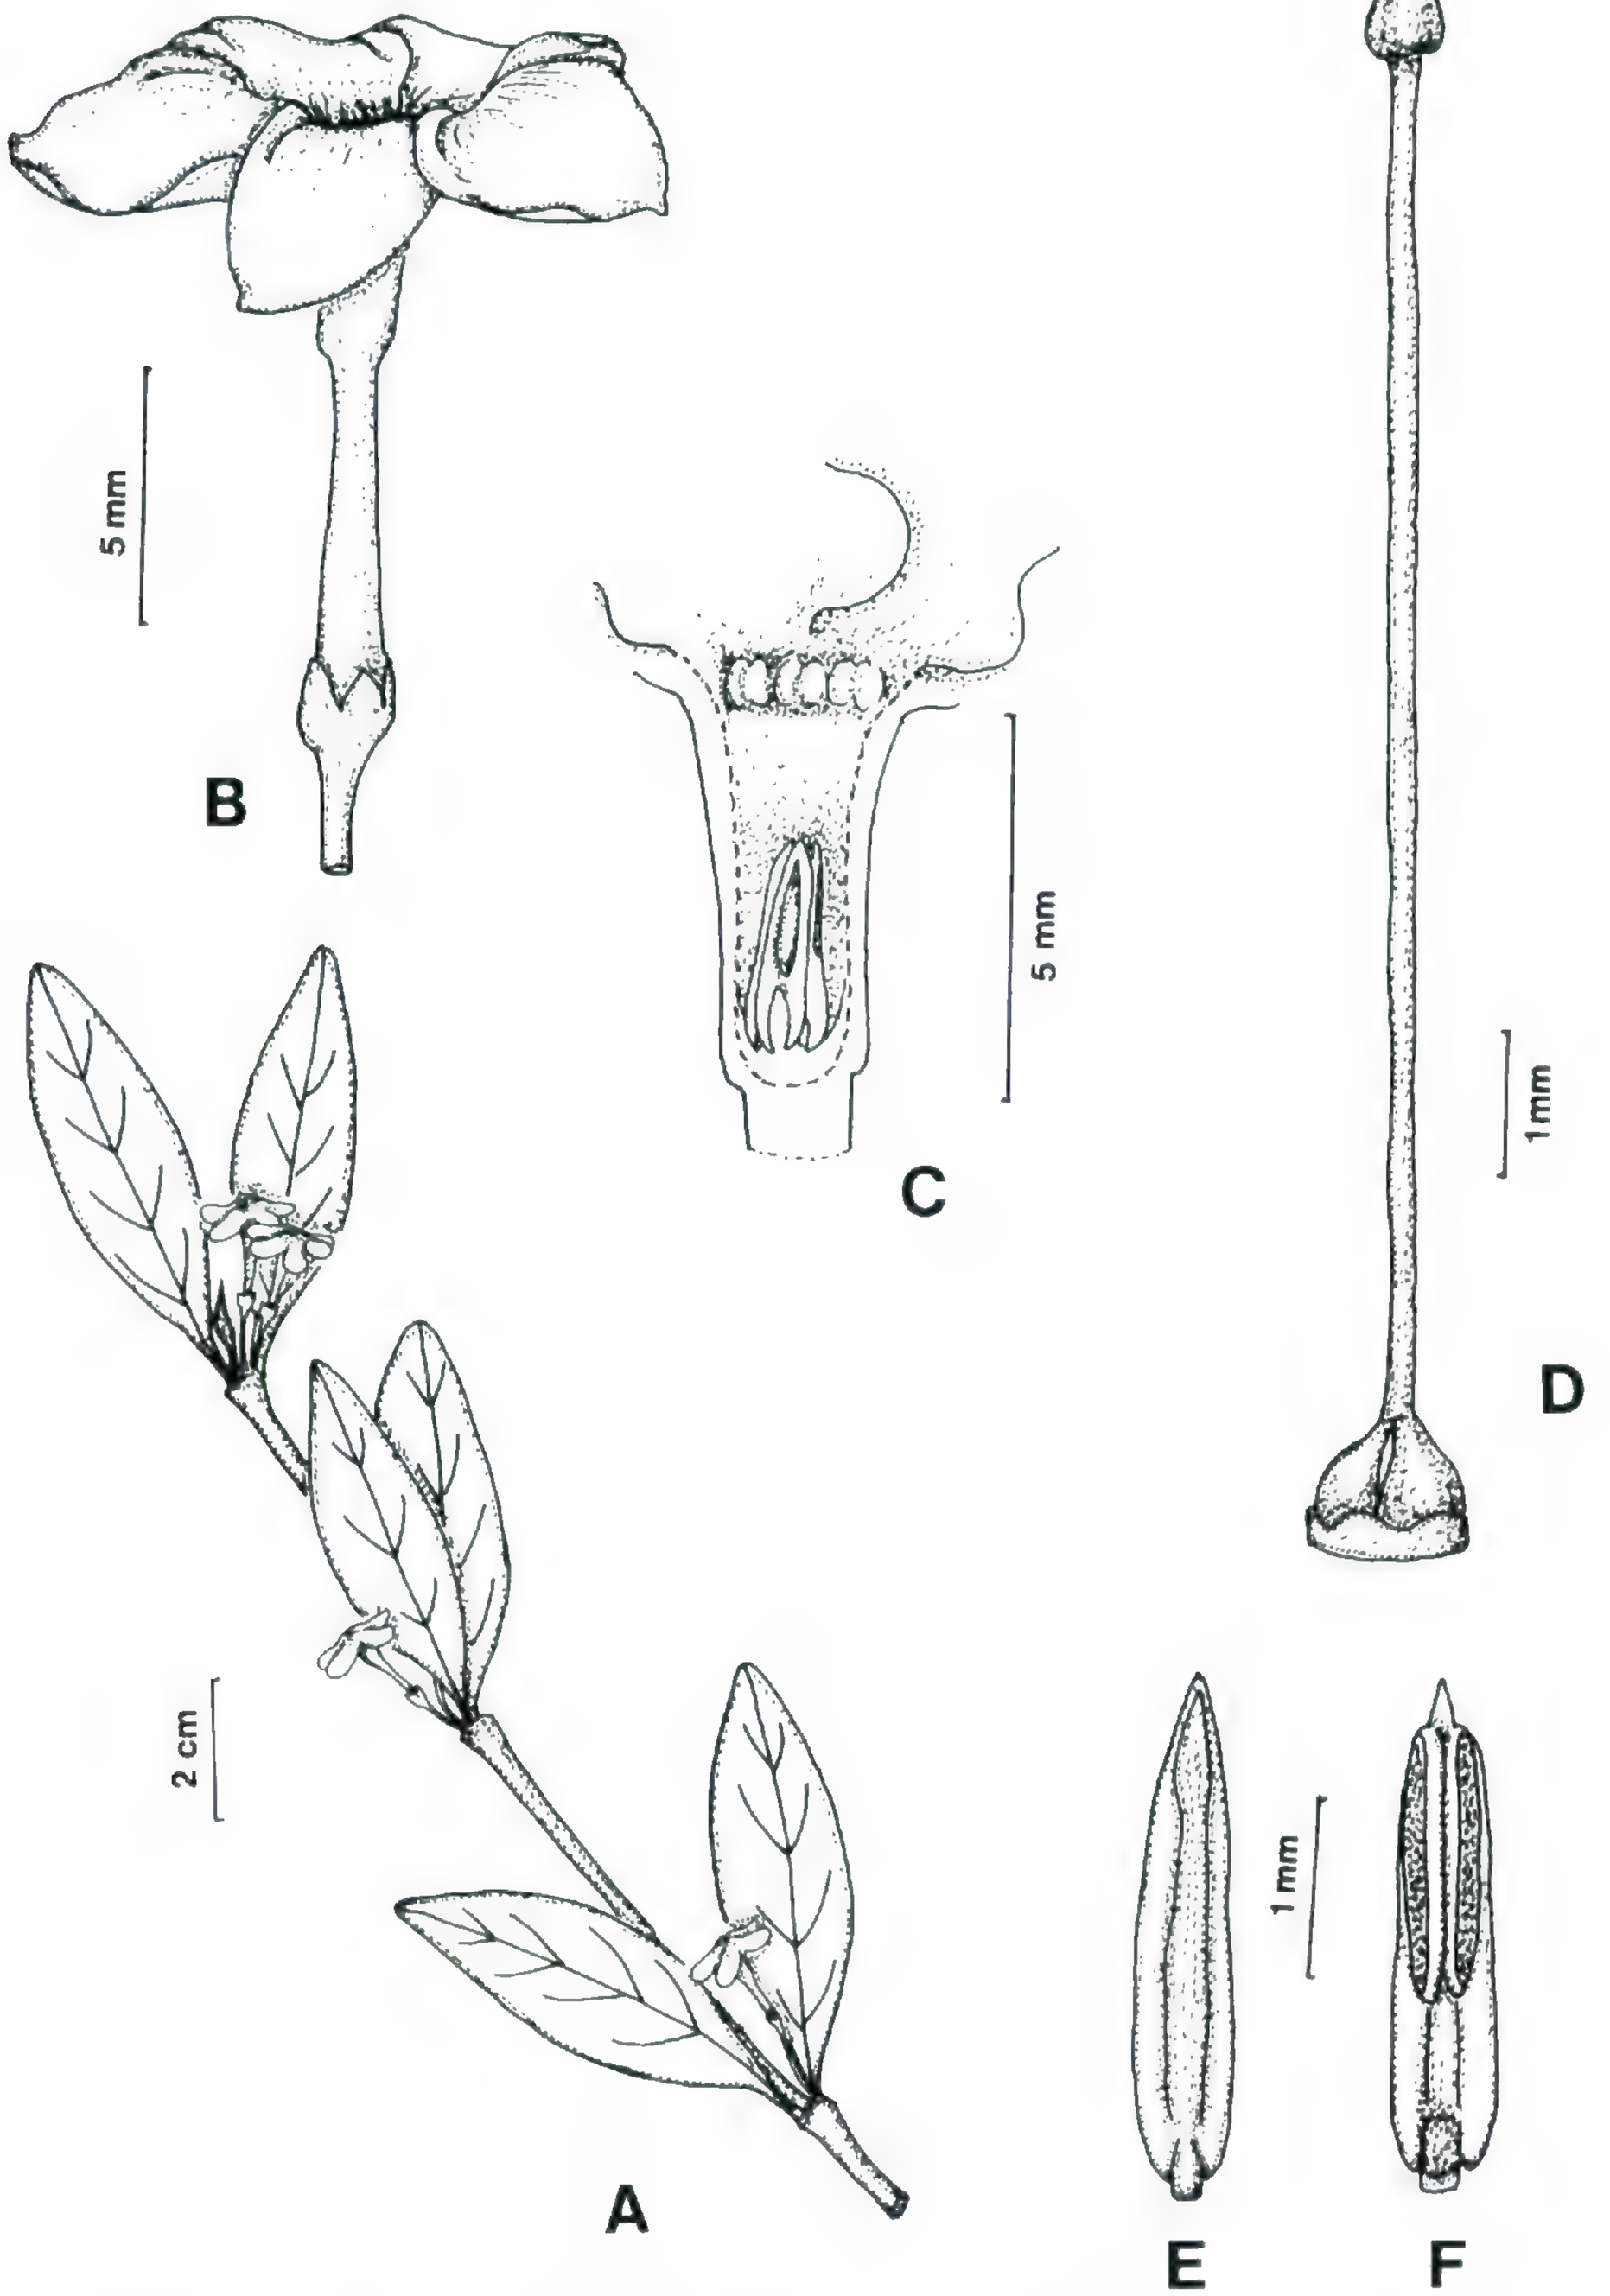

FIGURE 2. *Malouetia molongo*.—A. Habit. B. Flower.—C. Longitudinal section through upper portion of corolla showing coronal scales and positions of anthers. D. Gynoecium.—E. Anther, dorsal view.—F. Anther, ventral view. Based on the holotype.

1976, *Zarucchi et al. 1825* (holotype, US; isotypes, COL (n.v.), GH (n.v.), HBG, MO, USF). Figure 3.

Frutex vel arbuscula lactescens. Folia lamina lanceolata , apice caudata acumine 1–2 cm longa basi rotundata vel cuneata, utrinque glaberrima, in axillis nervi mediani interdum domatiis instructa, 5–10 cm longa, 1–3 cm lata; petioli 1–3 mm longi. Inflorescentiae axillares et (sub?)terminales e fasciculis (1–)2–4-floris compositae; calyx profunde lobatus intus extusque glaber, lobis anguste lanceolatis acuminatis; corolla viridi-alba vel flavida hypocraterimorpha, tubo 4–7 mm longo, 0.7–1.1 mm dia-

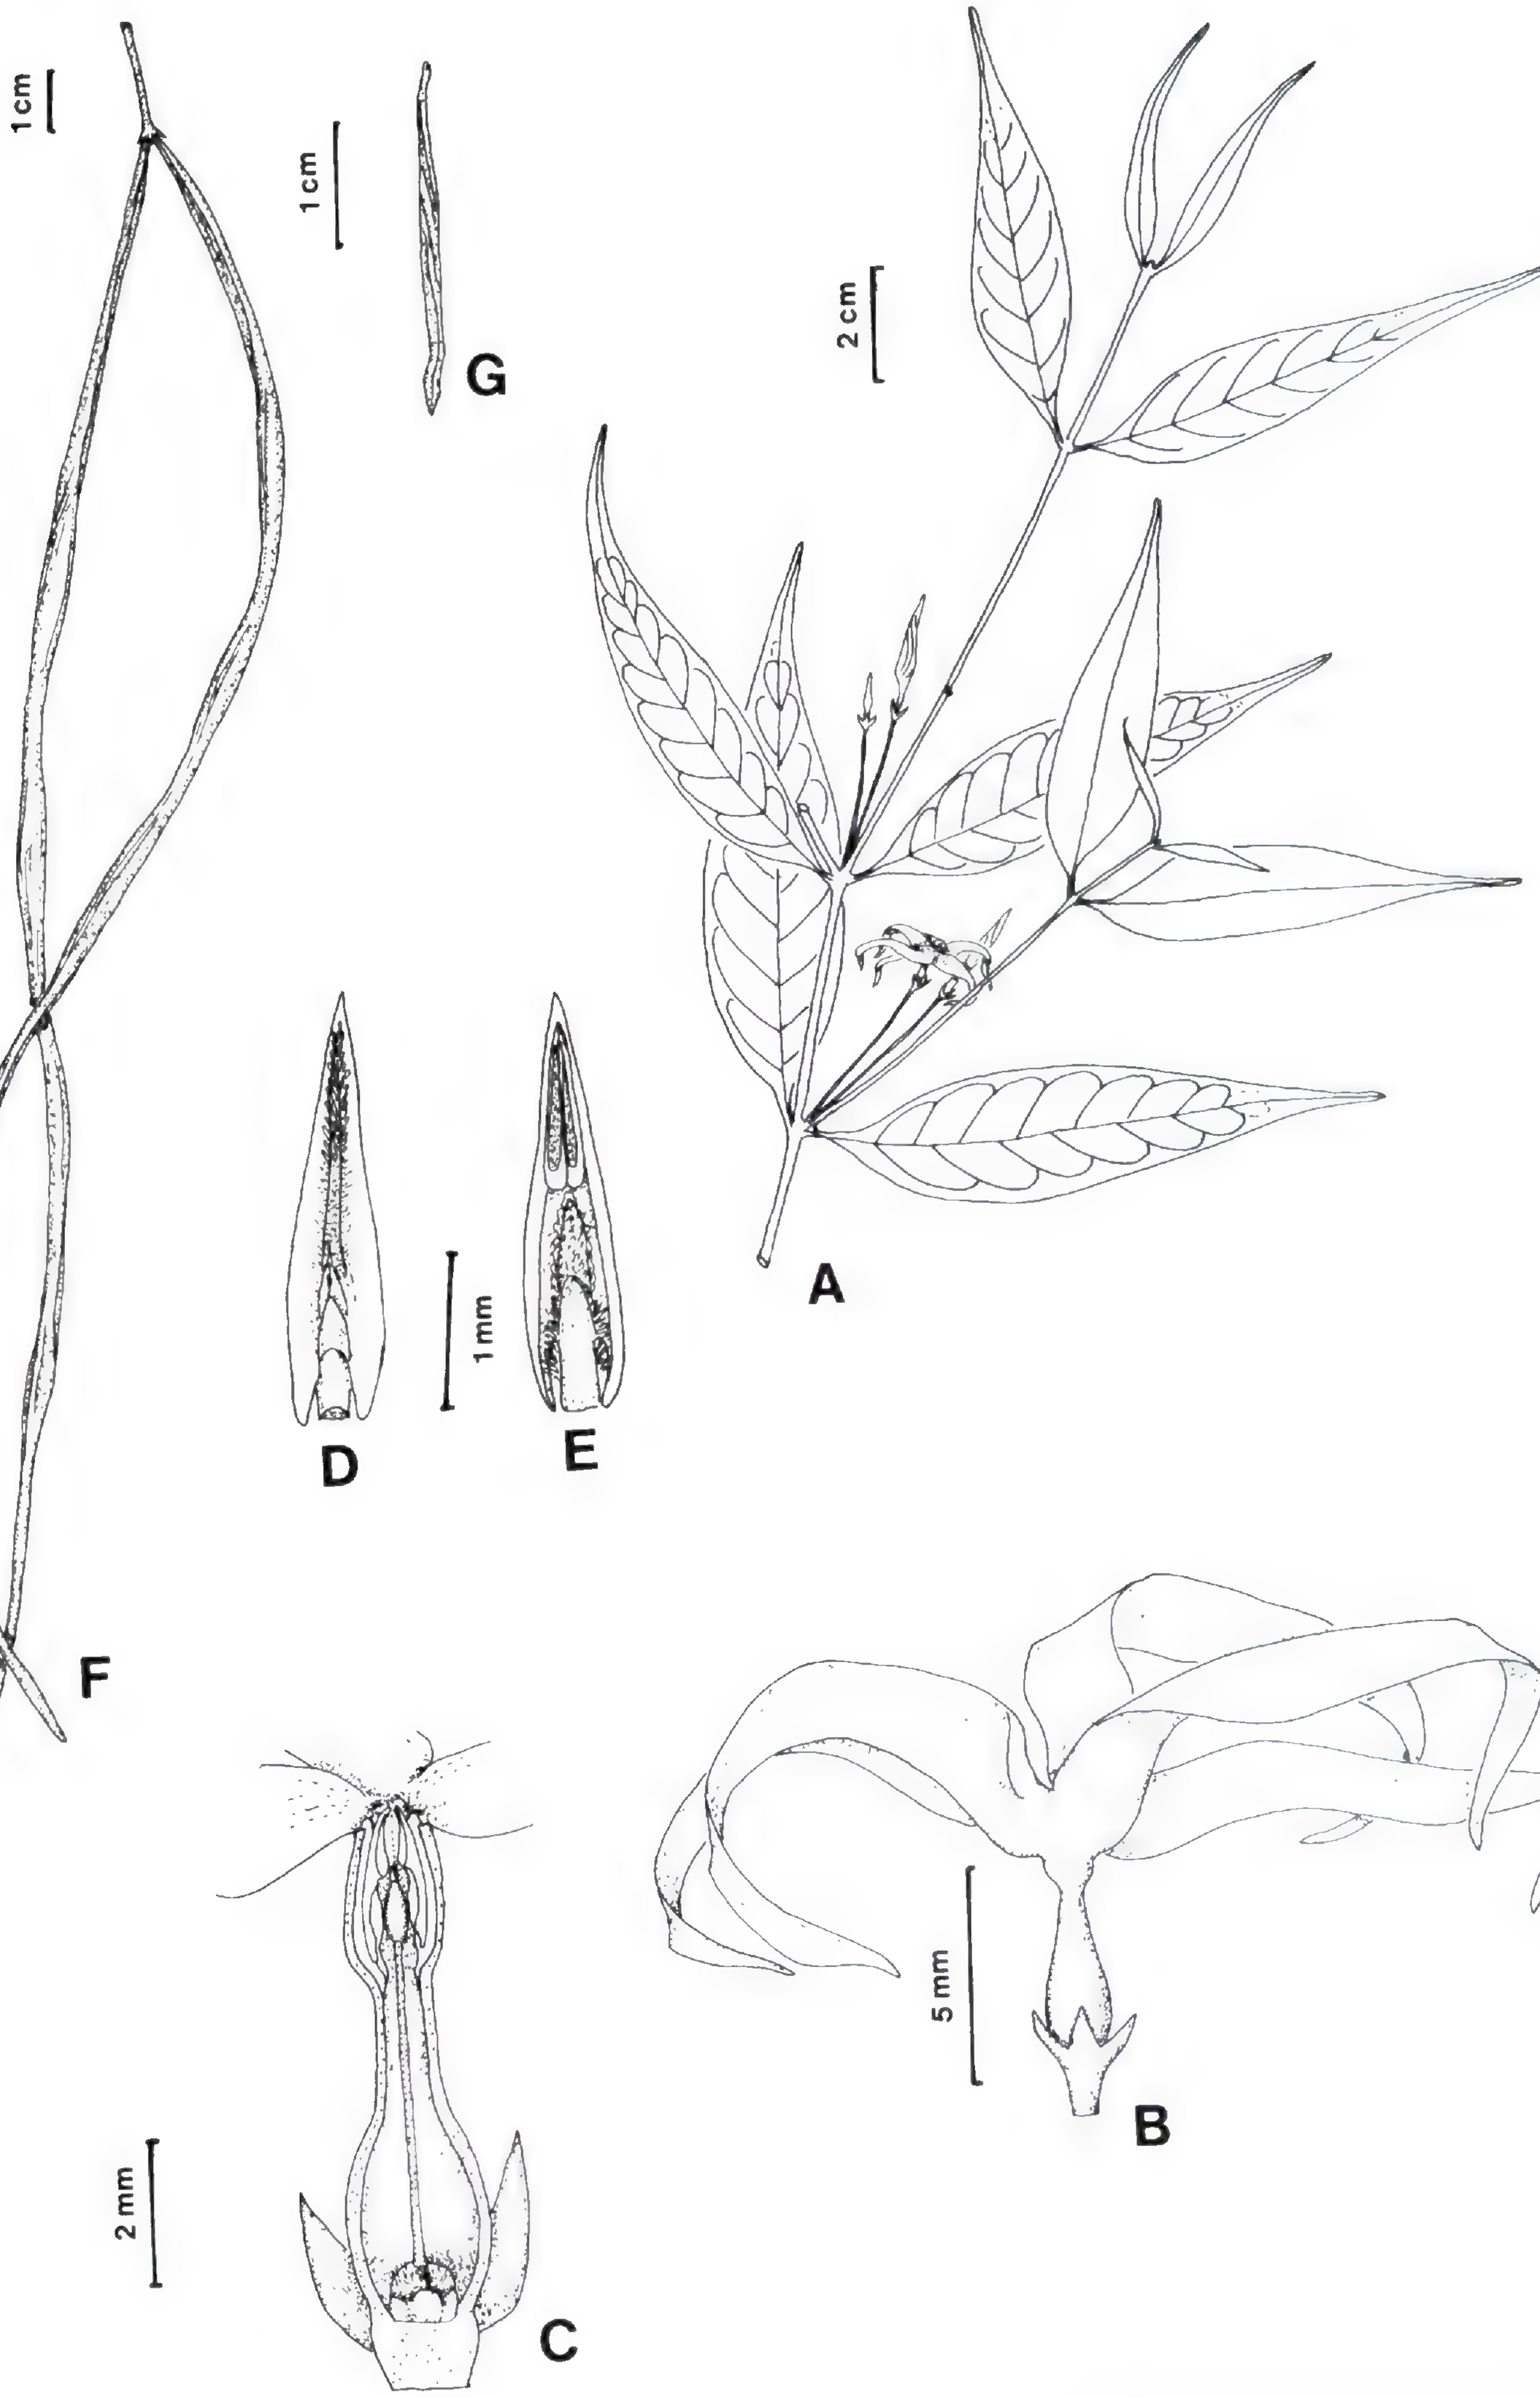

FIGURE 3. *Malouetia naias*.—A. Habit.—B. Flower.—C. Longitudinal section through flower showing positions of anthers.—D. Anther, dorsal view.—E. Anther, ventral view.—F. Fruit.—G. Seed. Based on the holotype.

metro basi inflato 1.2–2 mm diametro, lobis lanceolatis extus glabris intus prope basin granulato-puberulis vel villosulis 8 23 mm longis 1.8-3.5 mm latis; antherae basi faucis tubularis insertae, inclusae, tantum apice exsertae, dorso sparse pilosae; ovarium dense puberulum; ovula in utroque carpello 8 10 biseriatim affixa. Folliculi 2 graciles teretes glabri 25-28 cm longi, 3 mm diametro; semina lineari-cylindrica indumento microscopico denso et pilis dispersis 1–1.5 mm longis obtecta.

Shrubs or small trees 2–4(–8) m tall with sticky white latex; branchlets slender, glabrous, glossy reddish brown and flattened toward the nodes in younger portions, becoming gray and lenticellate with age. Leaves opposite, the blades thinly to firmly chartaceous, (5–)8–10 cm long, (1–)1.5–3 cm wide, lanceolate, the apex with acumen (1–) 1.5–2 cm long, rounded to cuneate at the base, completely glabrous on both surfaces, the upper surface often drying matte dark olive-brown to gray-green, the lower surface paler, with or without domatia in some of the axils of secondary veins with the midvein; secondary veins 8–9(–10) on each side, arcuate-ascending, anastomosing before the margin, impressed on the upper surface, prominulous on the lower surface; petioles 1–3 mm long, glabrous, reddish brown, with reddish brown pectinate glands at the base on each side. Inflorescences axillary or subterminal clusters of (1–)2–4 flowers; peduncle 1–2 mm long, glabrous, reddish brown; bracteoles ca. 1 mm long, narrowly ovate-triangular, glabrous, ciliolate at the margin. Flowers pedicellate, pedicels (1.3–)2–2.5 cm long, gracile to filiform, glabrous; calyx split almost to the base, glabrous on both surfaces, sometimes minutely puberulent near the apex on the inside, with 5 small flattened glands on the inside, the lobes narrowly lanceolate, acuminate, somewhat spreading, (1.5–)2–2.5 mm long, 0.3–0.8 mm wide, the margins densely and minutely ciliolate; corolla salverform, greenish white to cream or pale yellowish, the tube inflated at the base, the mouth occluded by 5 rudimentary coronal scales, the upper cupular part 1–1.5 mm long, 1–1.5 mm diam., the tube proper (3–)4.5–5.5 mm long, 0.7–1 mm diam. at the orifice, 1.2–2 mm diam. at the base, glabrous without, sparsely pilose within just below the level of stamen insertion, otherwise glabrous; lobes lanceolate (8–)10–15(–23) mm long, (1.8–)2–3.5 (–5) mm wide, glabrous on the lower surface, glabrous on the upper surface except near the base, this granular-pubescent to villosulous; stamens inserted near the orifice of the corolla tube, only the very tips exserted, narrowly lanceolate, 2.5–2.8 mm long, dorsally sparsely pilose, the side wings glabrous, acuminate and curving inward at the base; style-head cylindrical, 1–1.2 mm long, style filiform; ovary ovoid, apocarpous, bilocular, 1 mm high, densely puberulent, disc nectary glabrous, ca. half as long as the ovary, 5-lobed, the lobes connate for ca. ⅔ their length; ovules 8–10 per carpel, arranged biserially. Fruit apocarpous, glabrous, longitudinally finely striate, medium brown, composed of 2 slender, terete follicles 25–28 cm long, ca. 3 mm diam.; seeds linear-cylindric, 3 cm long, 1 mm diam., the ventral face longitudinally sulcate, the entire surface covered by a dense indument of microscopic hairs interspersed with a sparse scattering of thin, whitish to pale gold pilose hairs 1–1.5 mm long.

Additional specimens examined. COLOMBIA. VAUPES: Mitú and vicinity, *Zarucchi et al. 1810* (COL, GH, US, USF), *1847* (COL, GH, HBG, MO, US, USF). VENEZUELA. AMAZONAS: Caño de Cholo, 15 km NE of San Carlos de Río Negro, 4 km SW of Solano, *Liesner 4059* (MO, Z), *8560* (MO, VEN, WAG), *8879* (MO, WAG), *Gentry et al. 46425* (HBG). PERU. LORETO: Maynas, Mishana, Río Nanay, Estación Biológia Callicebus, *Vásquez & Jaramillo 3280* (MO, Z), *6108* (MO, Z).

Distribution. Colombia, Amazonian Venezuela, and Peru, in primary, secondary, and seasonally inundated lowland rainforest.

The specific epithet refers to the resemblance to the delicate water nymph.

This new species is most closely related to *Malouetia flavescens* (Willd. in R. & S.) Müll.-Arg. and *M. nitida* Spruce ex Müll.-Arg. However, *M. naias* is more delicate in all aspects than either of the above species. The following key is provided as an aid to identification.

KEY TO THE *MALOUETIA FLAVESCENS* SPECIES GROUP

1a. Leaves 9–18 cm long, 3–7 cm wide; corolla tube 6–10 cm long; seeds 3 mm diam. 2
2a. Anthers exserted ..... *M. flavescens*
2b. Anthers included ..... *M. nitida*
1b. Leaves 8–10 cm long, 1.5–3 cm wide; corolla tube 5.5–7.5 cm long; seeds 1 mm diam. ..... *M. naias*

4. **Malouetia pubescens** Markgraf var. **glabra** M. E. Endress, var. nov. TYPE: Venezuela. Apure: Rómulo Gallegos, Río Capanaparo, near Hato Carabali, *Davidse & Gonzales 16028* (holotype, MO; isotypes, NY, VEN).

A var. *pubescens* lamina foliorum subtus glabra et petiolis glabris differt.

Small trees up to 12 m tall with white latex; branches glabrous with a glossy blackish varnish. Leaves decussate, 8–15 cm long, 1.8–6.5 cm wide, the blades membranous, oblong-elliptic, the apex

acuminate, cuneate to obtuse at the base, glabrous and drying intense green on both surfaces; domatia usually present in some of the axils of the secondary veins with midvein; secondary veins 6–9 on each side, slightly impressed on the upper surface, prominulous on the lower surface; tertiary venation rather obscure on the upper surface, distinctly reticulate on the lower surface; petioles 2–4 mm long, glabrous. Inflorescences (10–)20–30-flowered, in terminal and axillary clusters; peduncle 1–2 mm long, glabrous. Flowers pedicellate, pedicels 2.5–5.5 mm long, glabrous; calyx 1–2 mm long, 1–2 mm diam., minutely puberulent on the outer surface, the inner surface with 5 small glands near the base of the lobes, the lobes 0.5–1 mm long, ovate, acute, the margins minutely ciliolate; corolla salverform, white to yellowish white, the tube 3–3.5 mm long, 0.5–0.8 mm diam., enlarged at the base, constricted at the orifice by 5 bilobed rudimentary coronal scales, glabrous on both surfaces, the lobes 4–5.5 mm long, 1.2–2 mm wide, oblong-ovate, acute, spreading or slightly reflexed, minutely puberulent on both surfaces; anthers inserted near the orifice of the corolla tube, almost completely exserted, 1.5 mm long, sagittate, the dorsal side barbellate, the side wings glabrous, basal appendages fused to the connective, slightly incurved, the ends blunt; style-head conical; ovary apocarpous, bilocular, 1 mm high, ovoid, sparsely puberulent at the apex, surrounded at the base by a 5-lobed disc nectary; ovules 10–12 in each carpel, arranged biserially. Fruit apocarpous, glabrous, dark brown, longitudinally striate, composed of 2 slender, thinly woody follicles, 11–19 cm long, 4–4.5 mm diam.; seeds linear-fusiform, compressed, plicate, the ends acuminate, tapering diagonally, 2 cm long, 2.5 mm diam., with a dense indument of pale tan to ochre lanate hairs ca. 1.5 cm long; embryo straight, 1 cm long, the cotyledons about 4 times as long as the radicle.

Additional specimens examined. COLOMBIA. VICHADA: Parque Nacional Natural "El Tuparro," ca. 7 km NE of El Tapón, *Zarucchi & Barbosa 3764* (FMB, MO, Z), *3766* (FMB, MO, Z). VENEZUELA. BOLIVAR: Río Parguaza, near Pilon, *Wurdack & Monachino 41116* (F, NY, S, US).

Distribution. Apure and Bolívar, Venezuela, and Vichada, Colombia, in gallery forest.

The new variety differs from var. *pubescens* in having leaves completely glabrous on both surfaces. The two varieties, which occur sympatrically in Vichada, Colombia, show no habitat differences.

TICODENDRON: A NEW TREE FROM CENTRAL AMERICA

Jorge Gómez-Laurito[1] *and Luis D. Gómez P.*[2]

ABSTRACT

Ticodendron incognitum is named as a new genus and species, and the taxonomic position of this tree is discussed.

Despite many years of floristic research in various Central American countries, new findings still surprise botanists. Such is the case of a tree, here described as a new genus and species, which has puzzled many scientists in the field and in herbaria and which has produced much correspondence and discussion. Based on studies of embryology, palynology, wood anatomy, and other features, a new family of dicots will be published soon for this genus.

Ticodendron incognitum Gómez-Laurito & Gómez P., gen. et sp. nov. TYPE: Costa Rica. Alajuela: Reserva Forestal de San Ramón, ca. Colonia Palmareña, 900–1,200 m, 10°10′N, 84°35′W, 30 Mar. 1987, male and female tree, *G. Herrera, I. Chacón & A. Solís 515* (holotype, CR; isotypes, F, K, MO). Figures 1–5, 6.

Arbor dioicus vel polygamo-dioicus, 7–20 m altus, 40–80 cm diametro ad pectoris. Germinationis hypogaeus. Cortex exfolians; interna facies nonnulla aliquanda caeruleopurpurascens. Lignum spadiceum, durissimum. Ramulis teretis, 3–5 mm crassis, nodosis, sulcatis, griseis, versus apicem complanatis, juvenis pilosis, pilibus unicellulatis simplicibus vel raro apicem furcatis, pallide ambarinis, cicatricibus stipulorum delapsorum notatis. Stipulae subulatae, usque 15 mm longae, circumdatae, caducae. Petiolis 10–15 mm longis, supra sulcatis, juvenis hirsutis (vide supra), demum lenticellatis. Foliae alternae, lamina elliptico-ovata, 8–13 cm longa, 4–8 cm lata, subcoriacea, margine in parte superiore serrata, base cuneata, apicem acuminata supra glaberrima, infra glabrescente, juvenis utrinque lanatis, pilibus longioris, rigidis, acutis, nervis secundaris 8–13 paribus, regulariter arquatis, subopositis, paralellis, infra elevatis, supra canaliculatis, ceteri nervis sub lente reticulatis, flavislucem transmissa. Inflorescentiae secundatae. "Amenta" 1.5–4 cm longa, simple vel ramificata, aliquando flos feminea coronatis. Axis leviter fractiflexis, pilosis. Stamina numerosae, 2–4 verticillatae dispositae; (verticillum 8–12 mm diametrum) bracteae 3, latae ovatae vel deltoideae, 5 mm longae, 5 mm latae basae, mox deciduae; filamenta 2–3 mm longa, teretes, pilosa; antherae oblongae, 2 mm longae, basifixae; thecae geminatae, longitudinaliter dehiscentibus, connectivo subulato producto. Granula pollinis ca. 2 μm crassa, subglobosa, leviter. Flos feminea solitariae extremitatis surculorum dispositae. Pedicelis 3 mm longis, adpresopilosis. "Bracteae involucratae" 3, ovatae, 2.5–3 mm longae, adpreso-pilosae, mox deciduae. Perianthium tubus adpresso-pilosus, carnosus, viridis. Ovarium inferum, biloculare in perianthium tubus inclusum, placentatio axilis. Ovula 4 (ut videtur abortu 1), hemitropa. Stigmata 2, pilosa, 5–12 mm longa. Fructus asymetricus, unilateraliter inflatus, ovatis, basim rotundatis, apicem acutis, drupaceis, vix 7 cm longis, 4 cm crassis, viridis, mucilaginosis; in siccitatem putamen avellaneum, lignossimum, longistrorsum sulcatus.

Dioecious or polygamodioecious trees, 7–20 m tall, 40–80 cm dbh. Germination hypogeal. Inner bark reddish or purplish. Wood yellowish, very hard. Twigs 3–5 mm thick, flattened toward the tips, pilose when young. Stipules subulate, to 15 mm long, caducous. Petioles 10–15 mm long. Leaves alternate, blades elliptic-ovate, 8–13 cm long, 4–8 cm wide, subcoriaceous, the margins serrate in the upper part. The base cuneate, the apex acuminate. Glabrous above, glabrescent beneath, woolly in early stages, with 8–13 secondary veins. Male flowers arranged in amentlike inflorescences 1.5–4 cm long, these simple or branched, sometimes crowned by a solitary female flower. Stamens many, verticillate, surrounded by 3 bracts, these broadly ovate to deltoid, 5 mm long, 5 mm wide at base, early deciduous. Filaments 2–3 mm long, pilose; anthers oblong, 2 mm long, geminate. Female flowers surrounded by bracts, solitary on pedicels 3 mm long, these appressed-pilose. Bracts ovate, 2.5–3 mm long, appressed-pilose. Ovary inferior, bicarpellate, 4-locular, included in the

Etymology. *Tico*, a Costa Rican diminutive, and *dendron*, Greek for tree. Its unusual characters were first noticed by Costa Rican botanists.

The first known collection was made in this country at the beginning of the century by C. Wercklé (*s.n.*, US No. 1010451) near San Cristóbal. The specific epithet refers to its Hamamelidean relationships.

The new genus and species of Hamamelidean affinities (Gómez-Laurito & Gómez, 1989) has prompted much discussion: a possible relationship to Urticales (e.g., Ulmaceae or Cecropiaceae) has been suggested. Dilleniales (Wolfe, 1989) and Rosales have also been proposed as possible orders for *Ticodendron*. For some time, placement in the Ulmaceae was favored and our genus does resemble genera of this family (e.g., *Aphananthe* Planchon), but its morphology excludes *Ticodendron* from subfamilies Ulmoideae or Celtidoideae. As in the Ulmaceous genus *Zelkova* Spach, *Ticodendron* has drupaceous fruits and somewhat distichous, pinnately veined leaves, but has four hemitropous ovules, three of which abort very early in development. Leaf characteristics suggested to W. Burger (pers. comm.) a relationship to the Cecropiaceae, but our observations revealed a bicarpellate ovary and two well-differentiated and free stigmas, among other differences. The dry, hardened fruits bear a faint resemblance to those of *Corylus* L., and, when we first saw a vegetative specimen, we thought of *Carpinus* L., which reaches northern Nicaragua.

Several genera of Hamamelidales (e.g., *Tetracentron* Oliver, *Sinowilsonia* Hemsley, *Altingia* Noronha, and others) show many of the morphological characteristics of the new plant and suggest that its true affinities lie within this order, although its precise placement requires further study.

The venation and marginal teeth of *Ticodendron* leaves have been compared and found somewhat similar to those of fossil Juglandaceae (Hickey, fide Raven, pers. comm.). Some botanists initially proposed Flacourtiaceae as the proper family.

A possible relationship between *Ticodendron* and the Antillean *Picrodendron* Planchon, based on the similar appearance of the pistillate flowers, has been suggested (M. Grayum, pers. comm., 1987) but *Ticodendron* has simple leaves and strongly asymmetrical fruits. Further, its pollen grains are unusually small and not of the *Olfieldia*-type, which occurs in the Euphorbiaceae, where most modern authors place *Picrodendron* (Hakki, 1985; Hayden et al., 1984; Webster, 1975). Wood anatomy (Carlquist, in press) and reproductive morphology (Tobe, in press) point to Fagales.

Ticodendron incognitum forms sparse stands or is found isolated in the montane evergreen forest of Central America. In Costa Rica, it usually grows from 900 to 2,300 m elevation associated with *Aiouea costaricensis* (Mez) Kostermans, *Phoebe hammeliana* W. Burger, *Cedrela salvadorensis* Standley, *Eugenia lepidota* Berg, and other species. The common names given to this tree are *jaúl macho* and *jaúl nazareno* (male alder, purplish alder). Both names recall the alderlike habit of *Ticodendron* and the purplish tinge of fresh cuts in most of the trees. Also, it is called *duraznillo* and *candelillo morado*. The wood is used as firewood. It is fine-grained, dries a pale rosy-brown, takes a high polish, and is harder than that of *Alnus*.

A SECOND SPECIES OF THE AMPHI-ATLANTIC GENUS *ALONSOA* (SCROPHULARIACEAE) IN SOUTH AFRICA[1]

Kim E. Steiner[2,3]

ABSTRACT

A second species of the predominantly South American genus *Alonsoa* has been found to occur in South Africa, having been incorrectly classified previously as *Diascia unilabiata* (Linn. f.) Benth. Its correct combination in *Alonsoa* already exists and is here resurrected, along with a full description and synonymy. *Alonsoa unilabiata* differs from South American species in having oil-secreting trichomes in shallow corolla sacs and from the other South African species in its annual habit, dilated filaments, and acuminate, bilobed stigma. Flowers of *Alonsoa unilabiata* are self-compatible, but are usually out-crossed by *Rediviva* (Melittidae) oil-collecting bees. Differences between *Alonsoa* and *Diascia* are discussed.

Alonsoa Ruiz & Pavón is a small genus of approximately 16 species that until recently was believed to be restricted to the New World (Edwin, 1971; Hilliard & Burtt, 1984; Roux, 1986). It is concentrated primarily in the Peruvian Andes of South America but ranges north through Central America to Mexico and south to Chile and Bolivia; it also occurs in the Cape floristic region of South Africa.

Alonsoa is one of seven genera that Bentham (1876) placed in the Hemimeridae, the others being *Diascia*, *Nemesia*, *Diclis*, *Hemimeris*, *Colpias*, and *Angelonia*. Since the American genus *Angelonia* is now placed in its own tribe Angelonieae (Pennell, 1920; Barringer, 1983, 1985), the Hemimeridae, with the exception of most species of *Alonsoa*, are basically restricted to southern Africa.

The first *Alonsoa* (*A. peduncularis* (Kunze) Wettstein) species discovered in Africa was collected by Zeyher (*3485*) in the late 1830s from woody gorges around Uitenhage in the eastern Cape. The original description (Kunze, 1842) was prepared from cultivated plants at the Leipzig botanical garden. The source of that seed was Lehmann of Hamburg who obtained it from someone in South Africa. The original source is uncertain, but, due to the rarity of this plant, it may well have come from Zeyher's collection. No subsequent collections of this taxon were made until its discovery at a second locality in 1985 (Roux, 1986). Since this second site is far removed from areas of past or present cultivation, and since no known South American species have corolla sacs, Bentham's (1876) suggestion that the original specimen collected by Zeyher was naturalized from South America is highly unlikely. Evidently Bentham's reluctance to accept *Alonsoa* as indigenous to South Africa was due to the unusual amphi-Atlantic distribution that this would represent.

Out of a combined total of about 4,500 genera occurring in Africa (including Madagascar) and South America, approximately 115 (2.6%), including *Alonsoa*, are restricted to these subcontinents (Thorne, 1973; Hilliard & Burtt, 1984). Of these, only seven (0.2% of the full total) occur in the Cape flora of South Africa. Among genera shared between South Africa and America, *Alonsoa* is the only genus presently centered in the Andes. Except for a few widespread genera (e.g.,

[1] I thank J. P. Rourke for nomenclatural assistance, and D. Snijman and several anonymous reviewers for commenting on earlier versions of the manuscript. Peter Goldblatt kindly checked and provided photocopies of some early publications by Ruiz & Pavón; F. Astholm identified *Alonsoa meridionalis* var. *lactea*; and J. Manning drew Figure 5. The assistance of V. B. Whitehead in the study of *Alonsoa* pollination has been invaluable.

Limosella, *Lindernia*, and *Ilysanthes*) and the parasitic genera *Melasma* and *Alectra* with tiny easily dispersed seeds, *Alonsoa* is the only connection between South American and African Scrophulariaceae. This and other evidence led Raven & Axelrod (1974) to suggest that the Scrophulariaceae probably did not exist when the two subcontinents were close together. Thus, *Alonsoa* must have reached Africa subsequently by long distance dispersal.

In America, *Alonsoa* is characterized by racemose inflorescences, resupinate flowers with the corolla tube split to the base between the lower (morphologically upper) lobes, and oblong to elliptic, usually longitudinally furrowed seeds (Edwin, 1971; Hilliard & Burtt, 1984). South African members of the genus are additionally characterized by two shallow yellow sacs in the gamopetalous portion of the corolla at the base of the lateral corolla lobes (Figs. 1–4, 5A, B). These sacs are densely packed with oil-secreting trichomes (Hilliard & Burtt, 1984; Roux, 1986; Steiner, pers. obs.).

My current research on the annual *Diascia*

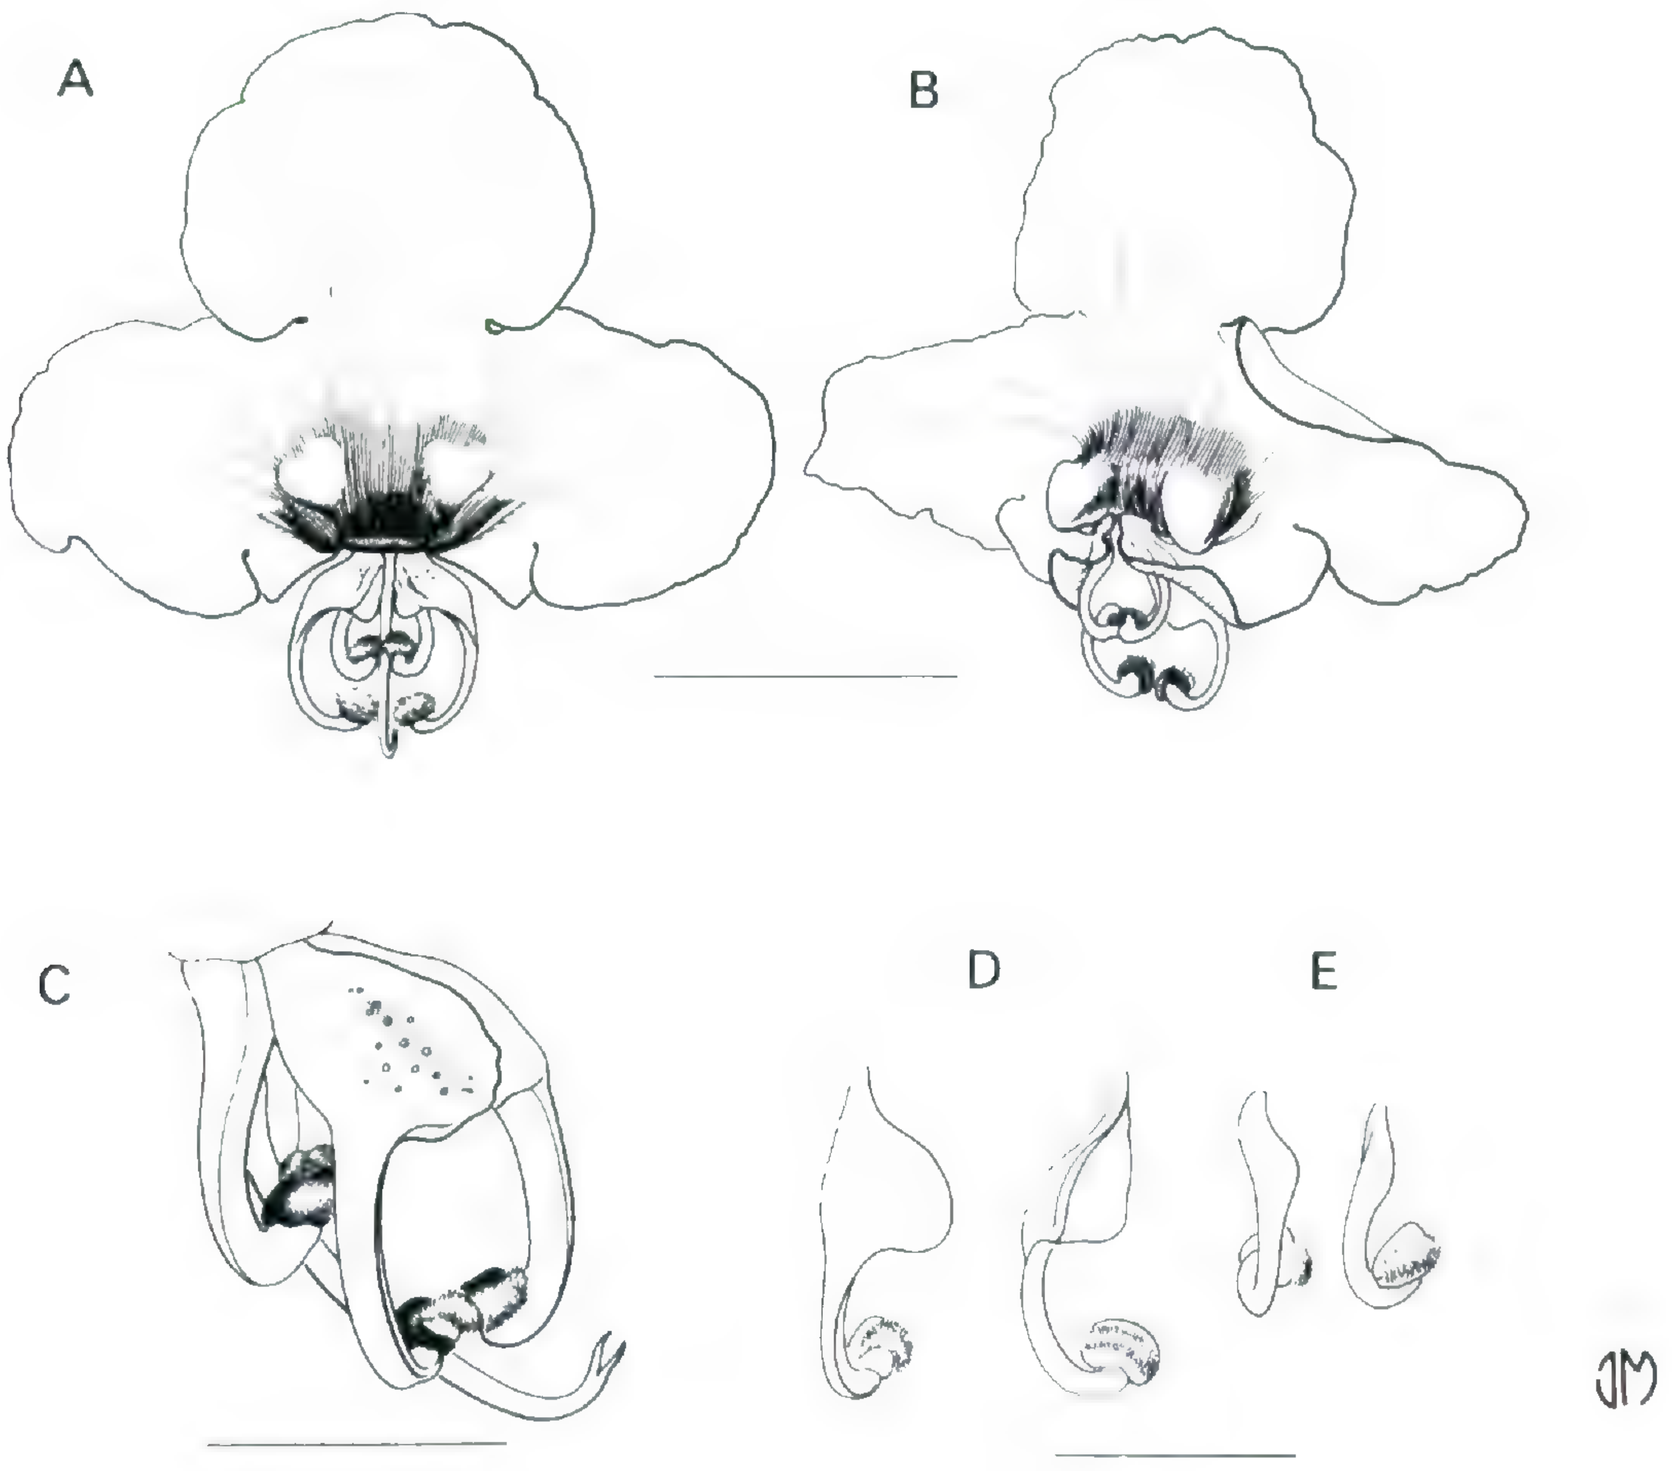

FIGURE 5. *Alonsoa unilabiata*—A. Front view of flower.—B. Rear view of flower.—C. Stamens, style, and stigmas. D. Anterior stamens.—E. Posterior stamens. Scale line for A and B = 1 cm. Scale lines for C–E = 0.5 cm.

species from the western Cape has revealed that a second species of *Alonsoa* has been incorrectly classified as *Diascia unilabiata* (Linn. f.) Benth. The presence of a second *Alonsoa* species in South Africa strengthens the unusual amphi-Atlantic connection within the genus and warrants an examination of the distinction between *Alonsoa* and *Diascia* in general, and the taxonomic history, variation, and reproductive biology of *Alonsoa unilabiata* (Linn. f.) Steudel in particular.

HABIT AND HABITAT

Alonsoa unilabiata is a winter-flowering (July–October) annual herb with simple to dissected leaves and pink to orangish pink resupinate flowers with dark purple-maroon centers. Contrasting with the dark center is a yellow translucent window or sac at the base of each lateral corolla lobe.

Alonsoa unilabiata occurs from near the west coast of South Africa (Elands Bay and Lamberts Bay), where it is found in loose sands of old stabilized dunes at about 100–200 m, northeast to the escarpment of the Bokkeveld Mountains (Nieuwoudtville area), and along the Roggeveld escarpment from Calvinia south to the northwestern edge of the Little Karoo (Konstabel and Tweeside) (Fig. 6). On the escarpments of the Bokkeveld and Roggeveld, these plants grow primarily in sandy to clay loam soils derived from shales, except around Nieuwoudtville where they occur on heavy doleritic clays. Drège collected *A. unilabiata* from the southwestern Cape near Cape Town in 1836, but no recent collections have been made from this area. *Alonsoa peduncularis*, in contrast, is known from only two localities in the southern and eastern Cape floristic region (Fig. 6).

There appear to be three fairly recognizable ecotypes of *A. unilabiata* associated primarily with different soil types. The differences between the ecotypes, involving mainly extent of leaf dissection and corolla sac shape, are not, however, great enough to warrant taxonomic recognition.

DISTINCTIONS BETWEEN *DIASCIA* AND *ALONSOA*

Corolla morphology of South American and South African species of *Alonsoa* is remarkably similar (Figs. 1–5A, 7). Most obvious is the resupination which places the enlarged morphologically lower lip in an upright position. Resupination was overlooked for *A. unilabiata* by Linnaeus f. (1781) and all subsequent botanists except Diels (1897), presumably because this character is obscured in

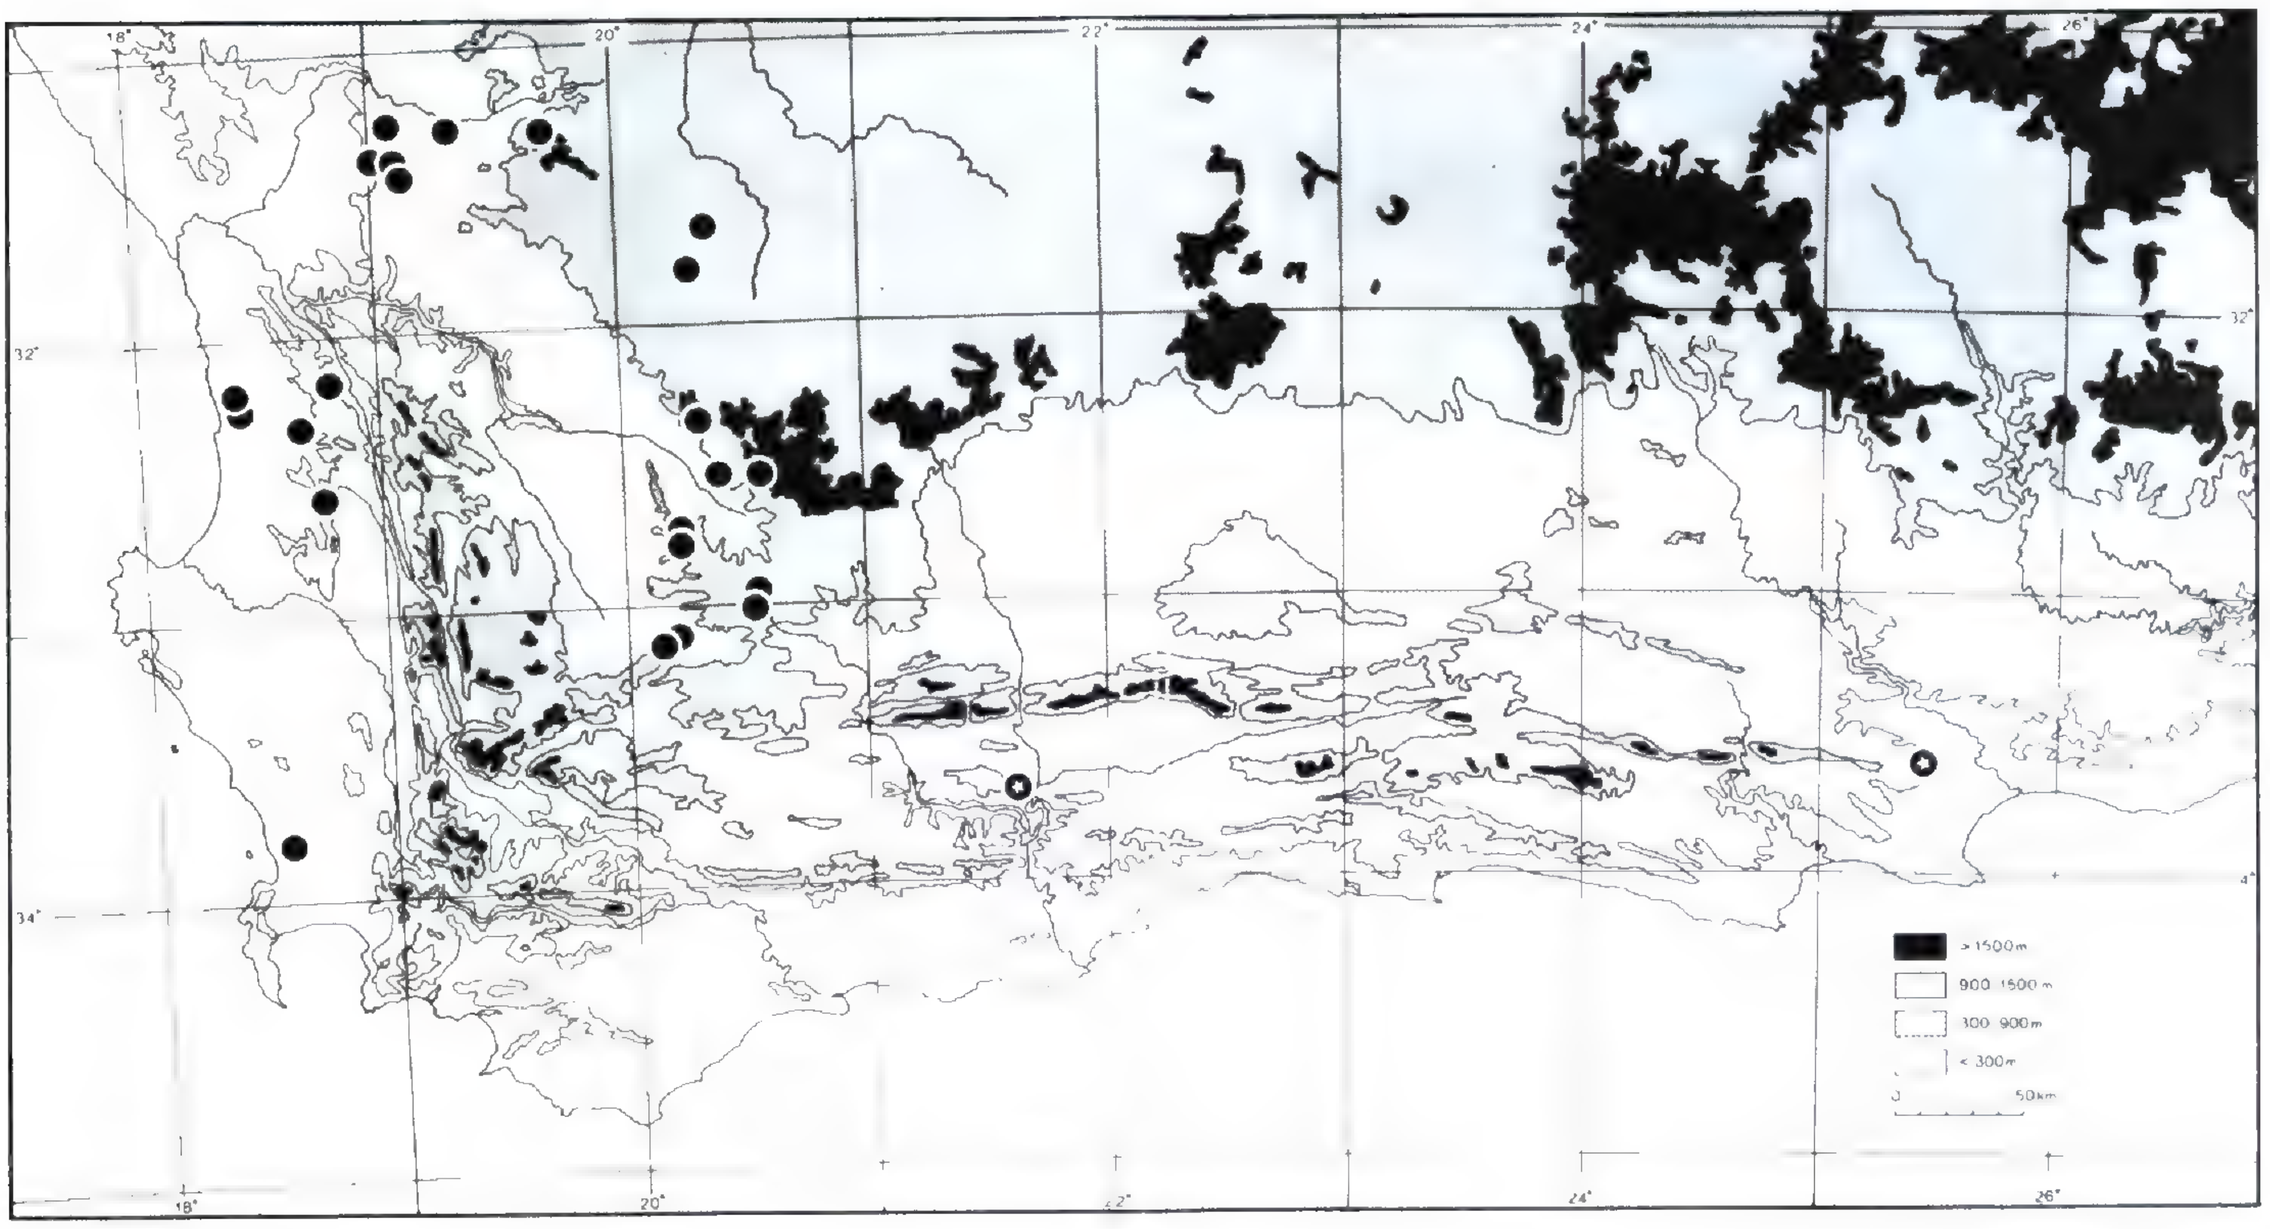

FIGURE 6. Distribution of *Alonsoa unilabiata* (solid circles) and *Alonsoa peduncularis* (star circles) in South Africa.

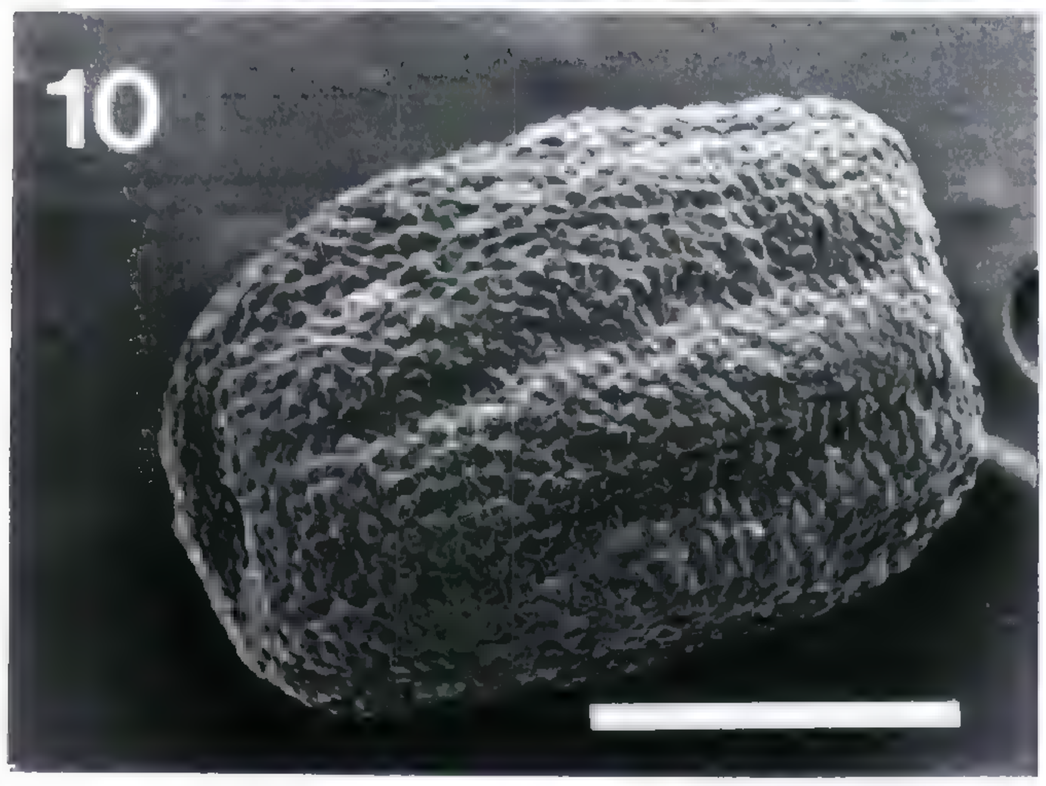
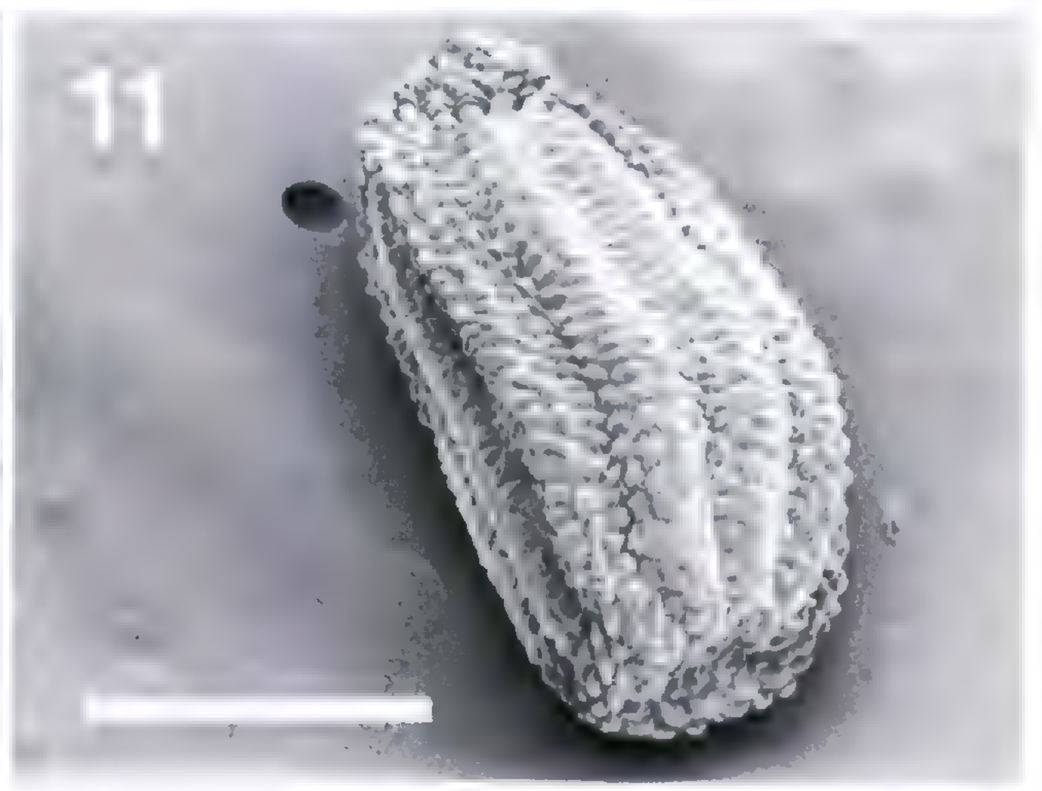
pressed material. *Diascia* species do not have resupinate flowers. Coupled with the rather strange appearance of the corolla caused by resupination in *Alonsoa* is the complete split in the corolla between the lower (morphologically upper) lobes (Fig. 5B), a character that Kunze (1842; in Hilliard & Burtt, 1984) erroneously attributed solely to *Alonsoa peduncularis* (as *Schistanthe peduncularis*). This condition is also found in *A. unilabiata*, as well as New World species *A. meridionalis* (L.f.) Kunze and others (pers. obs.; Edwin, 1971). The *Diascia* corolla always has a short but distinct tube (i.e., gamopetalous portion) without a split.

Another distinction between *Alonsoa* and *Diascia* is the form of the androecium. In *Diascia* (and in the related *Nemesia* and *Diclis*) the anterior (lower) filaments twist around the base of the posterior (upper) filaments, causing the upper part of the anterior stamens to be placed in a posterior position and the posterior stamens to appear in the anterior position (Hilliard & Burtt, 1984). No such twisting of the filaments occurs in *Alonsoa*, although a similar result without twisting is achieved in *A. peduncularis*, where the anthers of the lower (morphologically upper) stamens are situated above the anthers of the upper (morphologically lower) stamens. In *A. meridionalis*, the stamens are upright; in *A. unilabiata* (Fig. 5C) and *A. peduncularis* they project downward. This downward orientation in *A. unilabiata* is caused by the turning under of the lower (morphologically upper) rim of the corolla just above the point of filament attachment. *Alonsoa unilabiata* is set apart from all other *Alonsoa* species by its strongly dilated filaments (Fig. 5C–E).

FIGURE 7. Flower close-up of *Alonsoa meridionalis* subsp. *lactea* from El Angel, Ecuador.

Seed morphology further distinguishes *Alonsoa* from *Diascia*. As shown in Figures 8–11, *A. unilabiata*, *A. peduncularis*, and other *Alonsoa* species have wingless, oblong to elliptic seeds, usually with longitudinal straight (or undulate in *A. unilabiata*) furrows (Edwin, 1971). *Diascia* species have dorsiventrally flattened embryos and usually have elaborate wings or cuplike extensions on the seed coats. The pollen of *A. unilabiata* and *A. peduncularis* is tricolpate in contrast with the hexa-





FIGURES 8–11. Scanning electron micrographs of *Alonsoa* seeds.—8. *A. unilabiata* from Elands Bay.—9. *A. unilabiata* from Calvinia District.—10. *A. peduncularis*.—11. *A. meridionalis* from Peru. Scale lines = 0.5 mm.

to octacolpate grains of all examined *Diascia* species. *Diascia* and *Alonsoa* are distinguished in Table 1.

POLLINATION AND BREEDING SYSTEM

The major difference between South African and South American *Alonsoa* species is the presence in the former of a pair of shallow corolla sacs (Figs. 1–4, 5A, B) containing a dense patch of oil-secreting trichomes (trichome elaiophores). These trichomes consist of a two-celled stalk, bearing two or three secretory cells (Fig. 12).

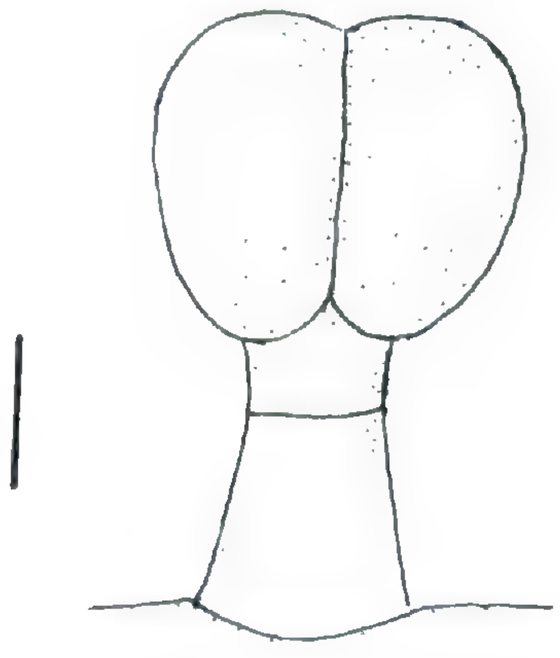


FIGURE 12. Trichome elaiophore from the corolla sac of *Alonsoa unilabiata*. Scale line = 15 μm.

The presence of elaiophores has a direct bearing on the manner in which these species are pollinated. *Alonsoa unilabiata* is pollinated by female oil-collecting bees in the genus *Rediviva*. Plants grow-

TABLE 1. Characters distinguishing *Alonsoa* from *Diascia*.

Alonsoa	*Diascia*
Flowers resupinate	Flowers never resupinate
Corolla split to the base between the morphologically upper lobes	Corolla with a short distinct tube, never split
Bases of filaments straight	Bases of filaments twisted placing anterior stamens in a posterior position
Pollen tricolpate	Pollen hexa- to octacolpate
Seeds oblong with longitudinal furrows and no wings	Seeds usually dorsiventrally flattened and with wings or with extensions of the testa fused into a cup

ing in the sandveld near Elands Bay are pollinated by two small (ca. 10 mm long) undescribed black species (*Rediviva* "*ruficornis*" and *R.* "*nigra*"), while plants on the Roggeveld escarpment from Grasberg to Sutherland (with the exception of Nieuwoudtville) are pollinated by a different undescribed species *R.* "*alonsoae*" and rarely by *R.* "*racemosae.*" At Nieuwoudtville, plants are visited by *R.* "*macgregori*" and *R.* "*racemosae.*" In all cases, bees place their heads at the base of the upper (morphologically lower) corolla lobe while inserting their forelegs into the oil-containing sacs. The dark central portion of the corolla as well as the yellow sacs are ultraviolet absorptive and contrast with the UV reflective corolla lobes (Steiner, pers. obs.). The presence of an ultraviolet absorptive region is common in oil-secreting species of *Diascia* and *Hemimeris* and appears to help orient the bee on the flower (Steiner, in press, pers. obs.).

Specialized scraping and absorptive setae on the forelegs of the *Rediviva* pollinators facilitate extraction of the oil, which is transferred to the hind legs and carried back to the nest (Whitehead & Steiner, 1985; Steiner & Whitehead, 1988; Buchmann, 1988). While probing for oil with its forelegs, the bee's abdomen curls into the cradle formed by the filaments, causing the anthers to rub against and deposit pollen on the upper tergites. Pollen is deposited from the abdomen onto the stigma of the next flower as the bee repeats this process.

The two *Rediviva* species at Elands Bay do not depend solely on *A. unilabiata* for oil, but also visit at least three other oil-producing species including *Hemimeris sabulosa* L.f. and two undescribed *Diascia* species. On the Roggeveld escarpment, with the exception of the Nieuwoudtville area, *A. unilabiata* is pollinated almost exclusively by *Rediviva* "*alonsoae.*" Even more unusual, however, is the apparent restriction of this bee to the flowers of *A. unilabiata* for oil, despite the cooccurrence of other oil-producing species at each site. This bee is the only one of 16 western Cape *Rediviva* species that is restricted to a single oil host plant (Steiner & Whitehead, pers. obs.).

Pollinator observations on other *Alonsoa* species are lacking. *Alonsoa peduncularis* occurs sympatrically with *Diascia patens* (Thunb.) Fourcade and may share the same *Rediviva* "*lepidos*" pollinator that collects oil from and pollinates that species, while New World species of *Alonsoa*, all of which lack oil-secreting trichomes, are probably pollinated by pollen-collecting bees. Many of the American species have large sturdy apically dehiscing anthers that form a cone around the style similar to that found in *Solanum*. These species are probably "buzz" pollinated (Buchmann, 1983) by large *Bombus* (Apidae) or *Centris* (Anthophoridae) bees.

The presence of shallow yellow corolla sacs in some annual *Diascia* species (*D. capensis* (L.) Britten, *D. diffusa* (Thunb.) Benth., *D. cardiosepala* Hiern, *D. elongata* Benth. et al.) probably accounts for the past confusion between *Alonsoa unilabiata* and *Diascia*. It is unlikely, however, that the presence of these sacs is indicative of a close relationship between *Diascia* and *Alonsoa* (Steiner, unpublished). Instead, it probably indicates a convergence based on adaptation to pollination by oil-collecting bees (Whitehead & Steiner, 1985; Steiner & Whitehead, 1988). Such unrelated parallel evolution of oil secretion has occurred numerous times in families as disparate as Orchidaceae, Iridaceae, Malphighiaceae, Krameriaceae, Scrophulariaceae, and Primulaceae; in unrelated orchid genera such as *Oncidium* and *Disperis*; and among unrelated Scrophulariaceae, such as *Calceolaria*, *Bowkeria*, and *Diascia* (Vogel, 1974, 1986; Simpson & Neff, 1981, 1983; Steiner, 1987).

Alonsoa unilabiata is self-compatible, as are other species in the genus, including *A. peduncularis* (Roux, 1986) and *A. meridionalis* (pers. obs.). Both of these last-mentioned species readily self-pollinate, and *A. peduncularis* can produce cleistogamous flowers under certain circumstances (pers. obs.). Flowers of *Alonsoa unilabiata*, however, self-pollinate only occasionally because of the spatial separation between anthers and stigma.

Alonsoa unilabiata is most closely allied to *Alonsoa peduncularis*, with which it shares the presence of corolla sacs containing trichome elaiophores, characters that must have evolved in Africa in conjunction with *Rediviva* oil-collecting bees. The annual habit, curved and dilated filaments, and acuminate two-lobed stigma, however, are all specialized features that set *A. unilabiata* apart from *A. peduncularis* and the South American species.

Synonymy and Description

Linnaeus f. (1781), Thunberg (1784), and Bentham (1846, 1876) all failed to realize that *Alonsoa unilabiata* (Linn. f.) Steudel has resupinate flowers. As a result, Diels (1897) described a new species (*Diascia nutans* Diels) for a collection of *A. unilabiata* from the Hantam Mountains near Calvinia. Discussing the resupinate corolla in his species, Diels stated that "evidently this development led to the same result as resupination of the *Alonsoa*

corolla, in fact the convergence developed so far that without the pits in the throat of the corolla, our species [*D. nutans*] would have to be placed in *Alonsoa*." The type of *D. nutans* was destroyed in Berlin, but the description and recent collections from the same locality (*Steiner 759*) suggest that Diel's plant must have been *A. unilabiata* (Linn. f.) Steudel.

When Bentham (1836) described *D. heterandra* he had not seen the type of *Alonsoa unilabiata* nor did he see it prior to his treatment of *Diascia* in De Candolle's *Prodromus* (p. 17, 1846). This may explain why he described Drège's collection as a new species in the first instance and why he retained it in his later publication. One of the characters used by Bentham to distinguish *D. heterandra* was the presence of sterile filaments. Judging from the poor preservation of the type as well as the relative ease with which anthers become detached in fresh material, it is likely that the missing anthers fell off during preparation and subsequent handling, since the specimen matches *A. unilabiata* in all other respects.

The type location for *Diascia heterandra* Benth., between Blouberg and Tygerberg, is considerably south of the main west coast distribution of *A. unilabiata*. Habitats near the type locality, however, are similar to those found around Elands Bay, where *Alonsoa unilabiata* can be locally common. The area between Blouberg and Tygerberg has been dramatically altered by the spread of urbanization and alien acacias, hence *A. unilabiata* is probably no longer there.

Diascia dissecta Hiern is simply a variant of *A. unilabiata* related to growth conditions. Its tall and spindly habit and more narrowly dissected leaves are typical of plants along the Roggeveld escarpment that grow up through shrubs.

Alonsoa unilabiata (Linn. f.) Steudel, Nomencl. Bot. ed. 2. 61. 1840. *Antirrhinum unilabiatum* Linn. f., Suppl. Pl. 279. 1781. *Hemimeris unilabiata* (Linn. f.) Thunb., Nov. Gen. Diascia dissecta Hiern, in Fl. Capensis 4: 153. 1904. TYPE: South Africa: Gerrit Snyman's farm in the Roggeveld Karoo, *Burchell 1289* (holotype, K).

Annual herb, erect, simple or branching; main stem 30–400 mm high, up to 2 × 2 mm in cross section, quadrangular, green to reddish purple, glabrous to glandular-villous or hirsute, more densely so towards base. Leaves simple, opposite, subopposite or upper stem leaves alternate, in up to 5 pairs per branch, 4–55(–60) × 3–25 mm, lanceolate to ovate, dentate to pinnatifid, upper surface glabrous, lower surface glabrous to glandular-villous-hirsute with translucent hairs, apex acute, base obtuse or attenuate; lobes 1.5–9 × 1.0–5.0 mm, linear to ovate, occasionally secondarily lobed or divided, the apex acute; petioles 2–20 mm long, glabrous to glandular-villous-hirsute. Flowers 1–4 in a loose terminal raceme, alternate; bracts 4–31 × 1–6 mm, becoming smaller upwards, linear to ovate, entire to pinnatifid, glabrous to glandular-villous-hirsute; pedicels 5– 18 mm long, ascending, resupinate, slightly longer in fruit, glabrous to glandular-villous-hirsute. Calyx segments 2.5–3.0 × 1.0 mm, narrowly elliptic, entire, lowermost (morphologically uppermost) slightly narrower and shorter, ca. 2 mm long, obtuse, entire, hirsute with minutely glandular translucent hairs. Corolla bilabiate, 12–24 × 13–26 mm; upper lip (actually lower lip in upper position due to resupination) of 3 lobes, upper lobe (morphologically lower lobe) ca. 6–11 × 7–13 mm, very widely ovate, sparsely glandular-villous-hirsute outside, glabrous inside; 2 lateral lobes 5–10 × 6–11 mm, depressed ovate, bases oblique, pink to orangish pink; gamopetalous portion below the 3 lobes 3–5 × 5–9 mm, very dark purple, bisaccate; sacs 2.2–3.3 mm long, openings 1.5–2.0 × 1.3–2.1 mm, cordate to transversely elliptic in outline, sacs projecting back and downward, yellow, inner surface densely covered with oil-secreting trichomes; lower lip completely split to the base; lower lobes (morphological upper lobes) ca. 2–4 × 4–7 mm, transversely elliptic and partly folded under, bases oblique; pink to orangish pink. Stamens didynamous, projecting downward and involute to form 2 concentric cordate rings, with outer ring 4.0–4.5 mm diam. and inner ring ca. 2.5 mm diam.; posticous filament 6–8 mm long, broadly dilated in the lower half into a kneelike projection and in upper half involute; anticous filament 4–5 mm long, lacking a broad dilation, involute; both deep purple, glandular-puberulent; anthers ca. 1 mm long, bearded with light blue hairs; thecae yellowish blue, opening outward; pollen tricolpate. Ovary 1.2–1.5 × 1.2–1.5 mm, widely ovate in outline, obtuse, glandular-puberulent; ovules 20–30; style 5.5–8 mm, involute, su-

bulate, persistent; stigma minutely bifid, with acute lobes; capsule 6.0–8.5 × 4–6 mm, pyriform, apex emarginate; seeds 1.4–1.9 mm, oblong to elliptic in outline, with shallow undulating longitudinal furrows, dark reddish brown.

Additional specimens examined. NOTES

A NEW SPECIES OF *ISOËTES* FROM TERRITORIO FEDERAL AMAZONAS, VENEZUELA

While preparing a treatment of the genus *Isoëtes* for the *Flora of the Venezuelan Guayana*, several specimens from Territorio Federal Amazonas in Venezuela were found to represent an undescribed and distinctive species. This species is described and compared with other species of the northern Andes.

The various terms for organs and their character states follow Hickey (1985, 1986a); terminology for spore morphology follows Hickey (1986b). Two-dimensional shape characterizations for the ligule, labium and sporangium follow Radford et al. (1972).

Isoëtes vermiculata Hickey, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Depto. Atabapo, Cerro Marahuaca, submerged in small rivulet, 03°37′N, 65°23′W, 2,520–2,650 m, 26–27 Feb. 1985, *Steyermark & Holst 130758* (holotype, MO; isotypes, MU, Ven n.v.). Figures 1–3.

Ab aliis speciebus neotropicis differt subula triquetra, velo fere completo, ligula habenti pulvino depresso-ovato, auriculato, et macrosporis rugulatis vel subretatis.

Corm globose, 20–35 mm diam., bilobed; roots arising synchronously from the circumbasal fossa. Leaves numerous, stiff, erect to strongly recurved, to 85 mm long, 8–19 mm wide at the base, 1.3–2.0 mm wide at mid-length; alae chartaceous to submembranaceous, hyaline proximally, castaneous to blackish brown or dark green distally, 1.5–2.5 mm wide at the sporangium, 10–20 mm long (24–29% of the total leaf length), the apices on outer leaves acute to free, those on inner leaves attenuate; subula triquetrous, dark green, the apex acute to attenuate, corneous; fibrous bundles absent; scales and phyllopodia not seen. Sporangia obovate to widely depressed-obovate in surface view, hyaline, unspotted, 4.0–4.5 mm long, 2.5–4.0 mm wide, basal. Velum complete to incomplete, covering 66–100% of the sporangium. Ligule margins delicate, ephemeral; the cushion dark, persistent, depressed-ovate, 0.23–0.40 mm high, 1.1–1.4 mm wide, auriculate. Labium absent or only poorly developed. Megaspores white, slightly shiny, rugulate to subretate, often with a weakly developed, smooth girdle, 880–990 ($\bar{x}$ = 943) μm diam.; proximal ridges straight, broadly rounded, the equatorial ridges straight or scalloped, broadly rounded. Microspores pale reddish brown, scabrate, 35.5–45.8 ($\bar{x}$ = 40.1) μm long, 25.2–34.4 ($\bar{x}$ = 29.5) μm wide.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Depto. Atabapo, summit, Cerro Marahuaca, 03°50′N, 65°28′W, 2,580–2,600 m, 30 Mar.–1 Apr. 1983, *Steyermark & Delascio 129259* (VEN); submerged in stream, attached to margin in shallow water, 03°40′30″N, 65°26′20″W, 2,560 m, 10–12 Oct. 1983, *Steyermark 129586* (MO, UC).

Isoëtes vermiculata is known only from streambanks on the summit of Cerro Marahuaca of the Territorio Federal Amazonas in southern Venezuela. The species is named for the distinctive wormlike markings on the proximal and distal faces of the megaspores.

Isoëtes vermiculata is a distinctive element of the *Isoëtes* flora of northern South America. When fertile, it is most easily identified by its large, rugulate to subretate megaspores and depressed-obovate sporangia with nearly complete vela. It can be identified vegetatively by a combination of the triquetrous (three-sided, with rounded angles) subula, depressed-ovate, auriculate ligular cushion, and absence of a well-developed labium. The only other species of *Isoëtes* known from this region of Venezuela is *I. triangula*, a lowland, seasonal species having a trigonal (three-sided with sharp angles) subula, large labium, and pustulate megaspores, and not having a velum.

Not enough is known about *I. vermiculata* to judge affinities with other species in the genus. The triquetrous subulae and rugulate to subretate megaspores of *I. vermiculata* are, however, similar to

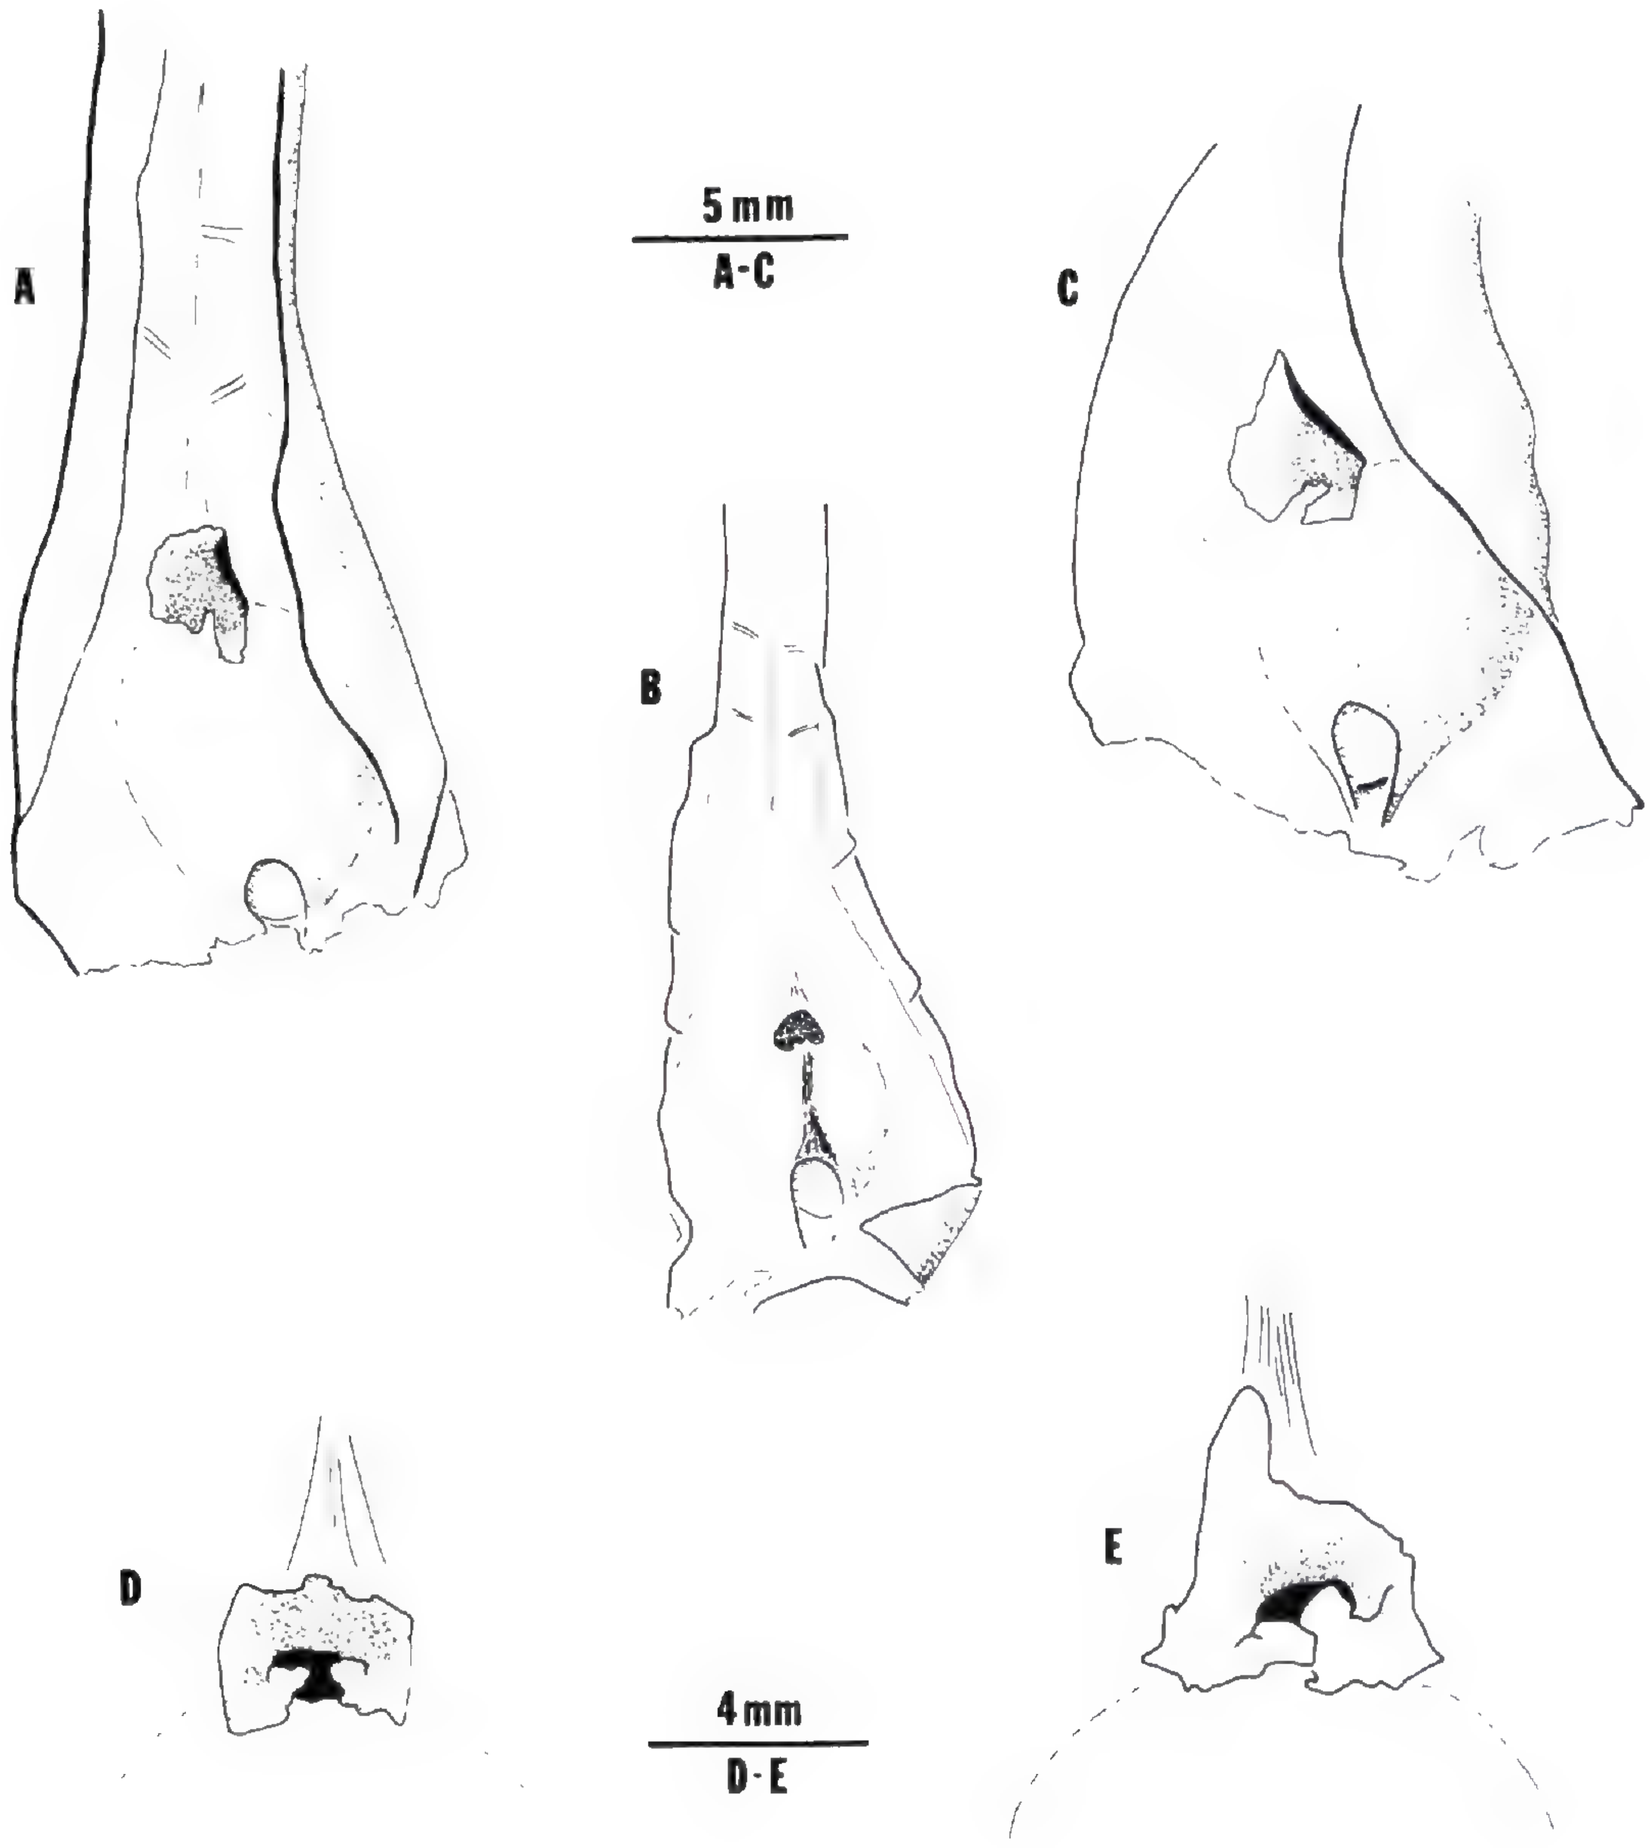

FIGURE 1. Leaf base morphology of *Isoëtes vermiculata*.—A. Microsporophyll showing nearly complete velum and partially eroded ligule, *Steyermark & Holst 130758* (MU).—B. Megasporophyll with a nearly complete velum and an entire ligule, *Steyermark 129586* (UC).—C. Microsporophyll on which only the ligular cushion remains, *Steyermark & Holst 130758* (MU). D, E. Variation in ligule form, *Steyermark & Delascio 129259* (VEN).—D. Ligule cushion with all of the ligular margin eroded.—E. Same as D but with portions of the upper ligular margin and marginal auriculate base remaining (black = foveola; stippled = cushion).

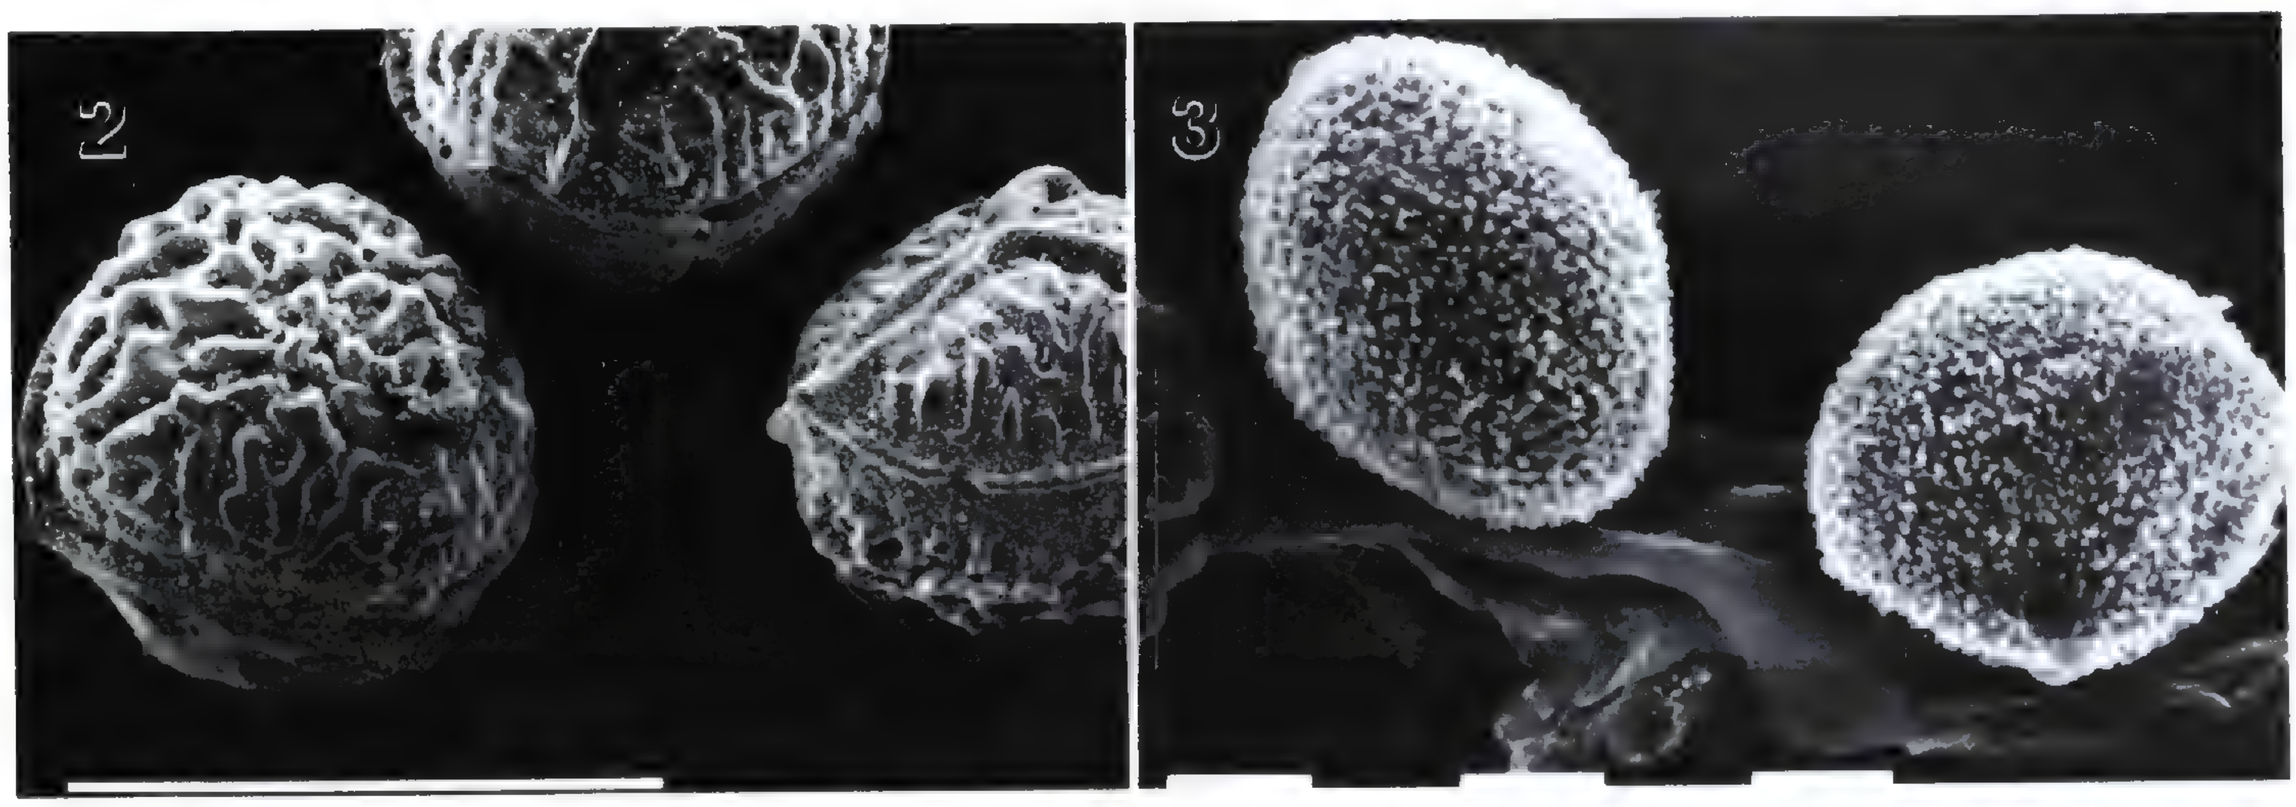

FIGURES 2, 3. Spores of *Isoëtes vermiculata*. —2. Distal and equatorial views of rugulate megaspores showing a nearly smooth girdle distal to the equatorial ridge, *Steyermark & Holst 130758* (MU). Bar = 1 mm.—3. Distal and equatorial views of scabrate microspores, *Steyermark & Holst 130758* (MO). Bars = 10 μm.

those of *I. novogranadensis*, *I. andina*, and *I. killipii*. Both *I. novogranadensis* and *I. killipii* are distinctive in having levigate microspores, whereas those of *I. andina* have the plesiomorphic echinate condition. The large spores of *I. vermiculata* suggest a hybrid of high ploidy level, perhaps $10x$ or $12x$. Whether this hybridization event took place when other taxa inhabited the area (perhaps during the Pleistocene) or whether it represents a morphologically and geographically distinct segregate population of a more widespread hybrid is open to question.

This research was supported by NSF Grant BSR 860672.

A NEW VENEZUELAN *VIROLA* (MYRISTICACEAE)

This note describes and illustrates a new species of *Virola* from Cerro Sarisariñama in the Venezuelan Guayana.

Virola is a genus endemic to the American continent with its center of diversity and greatest species richness in the western Amazon region. With this

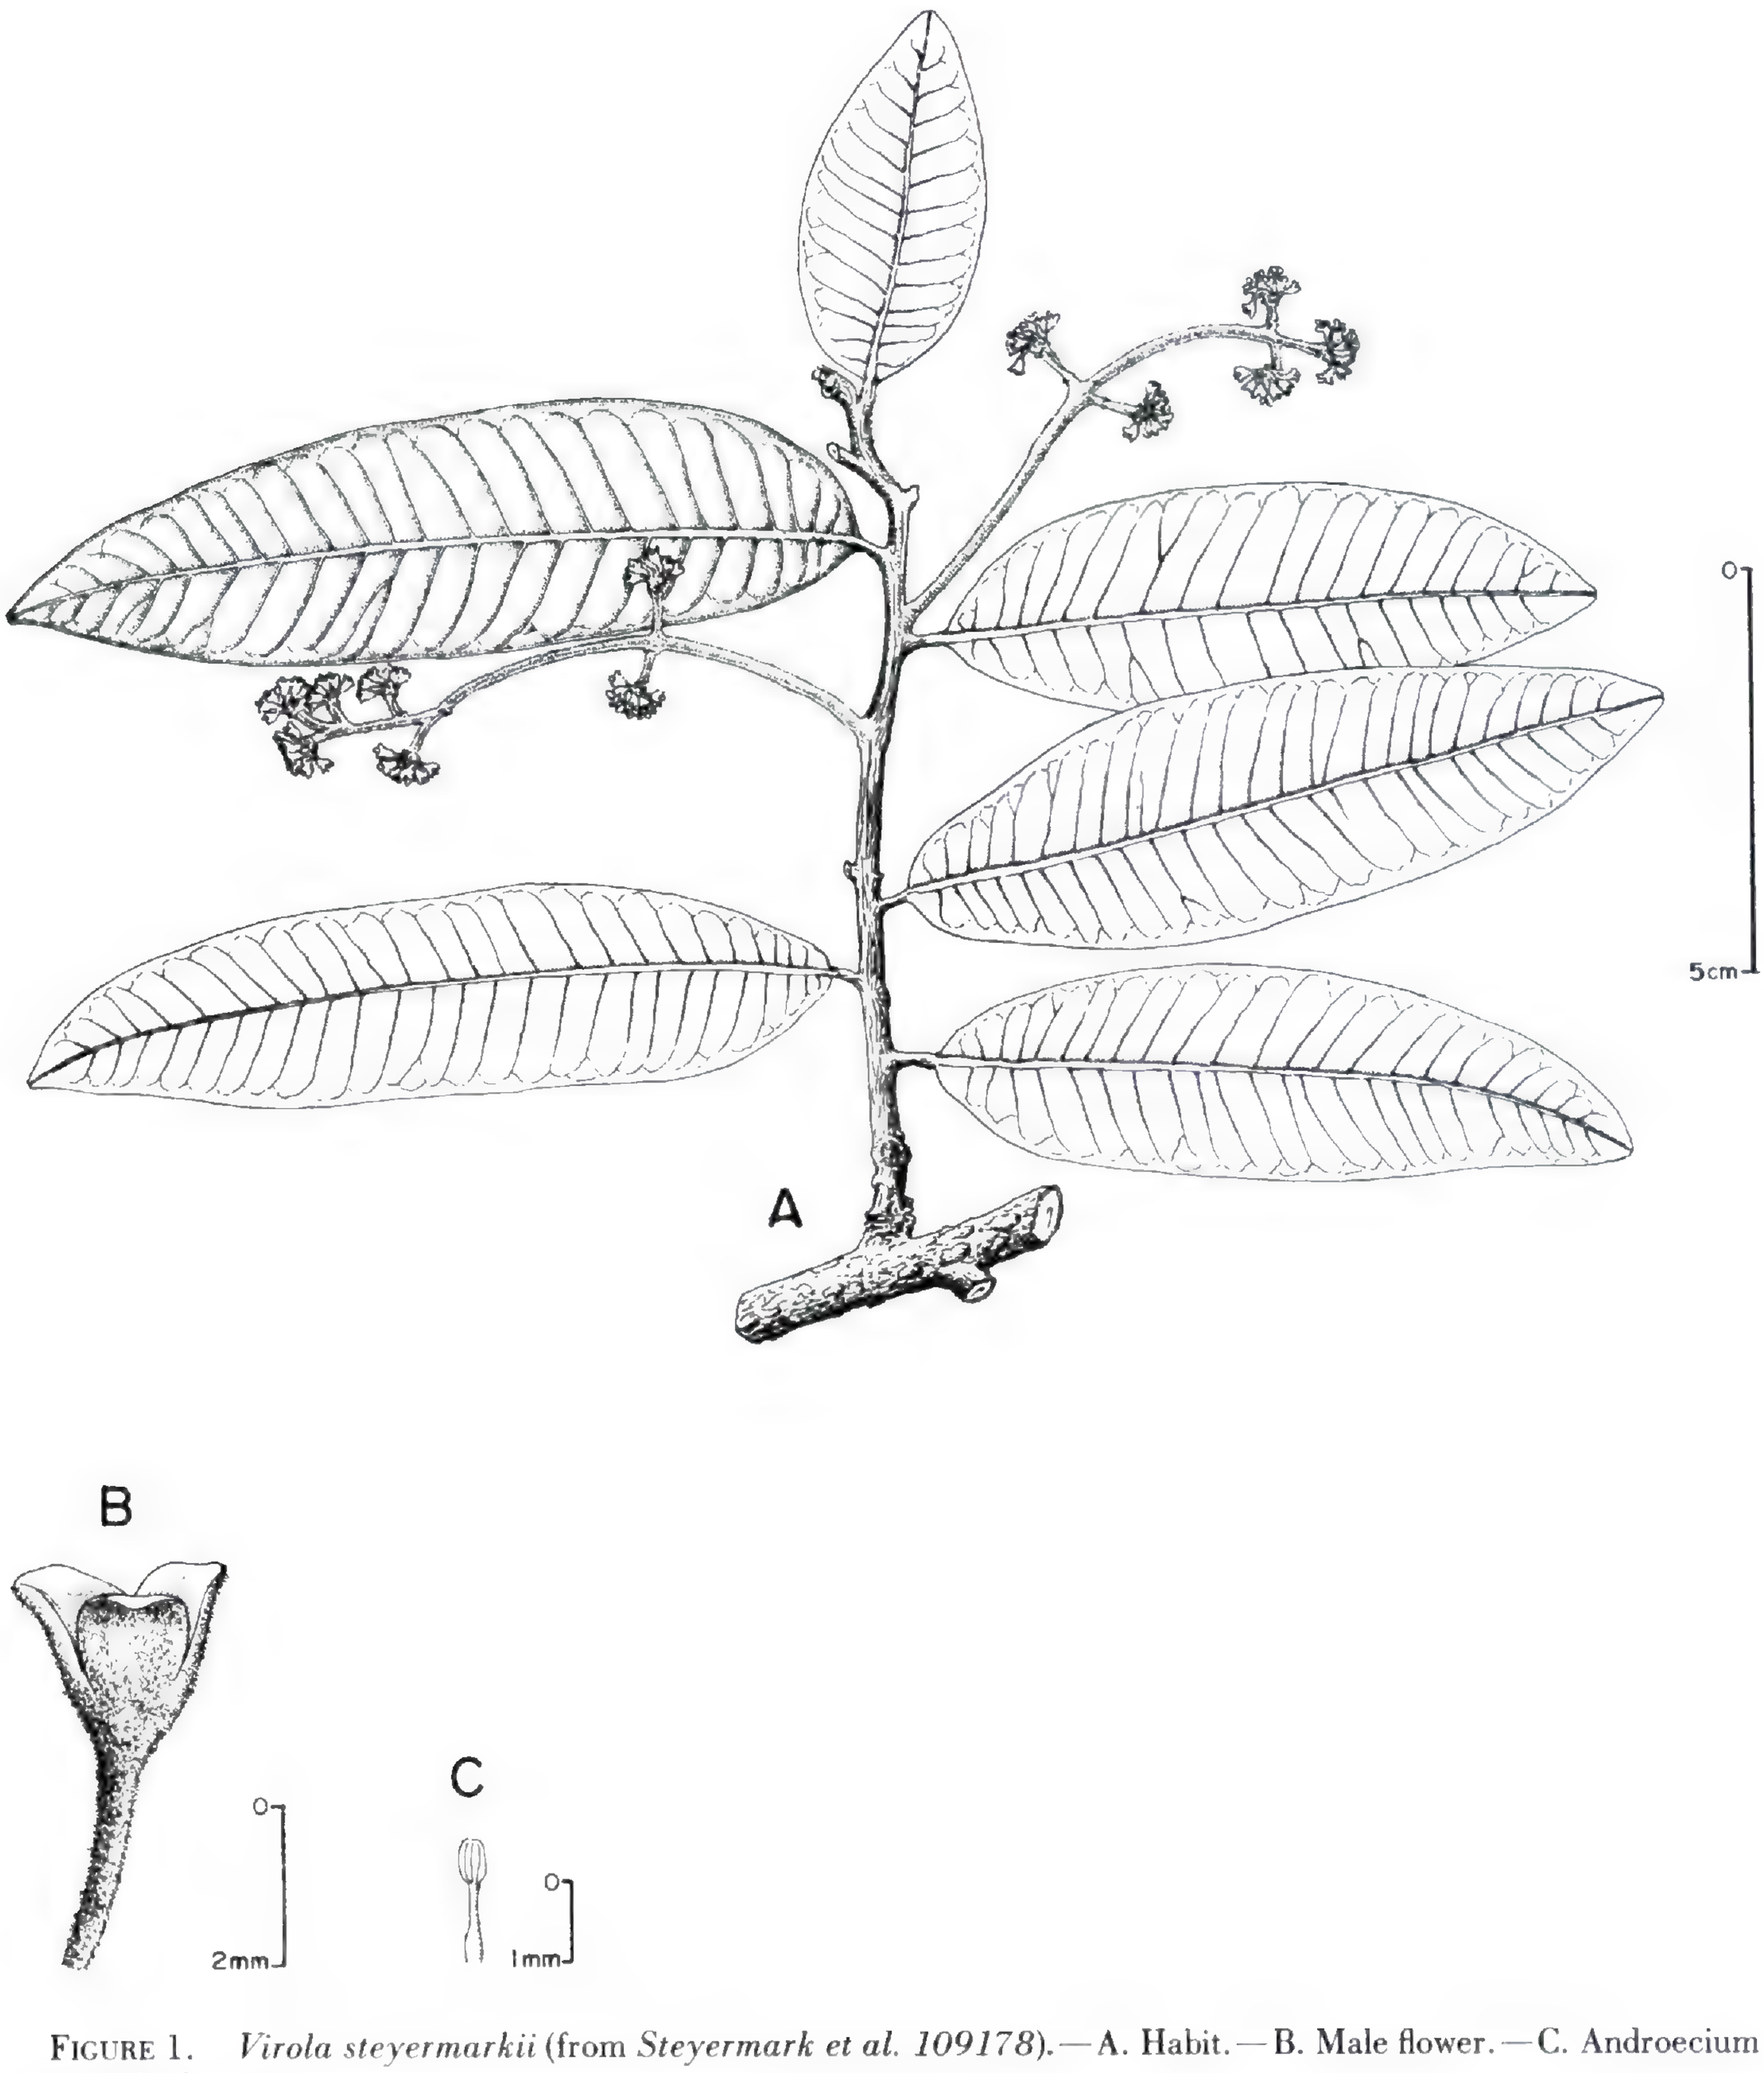

FIGURE 1. *Virola steyermarkii* (from *Steyermark et al. 109178*).—A. Habit.—B. Male flower.—C. Androecium from male flower.

ANN. MISSOURI BOT. GARD. 76: 1163–1164. 1989.

new species of *Virola*, there are now 13 Venezuelan species in this genus of 48 species.

Virola steyermarkii W. Rodrigues, sp. nov. TYPE: Venezuela. Bolívar: Meseta del Jaua, Cerro Sarisariñama, cumbre, porción nor-este, 04°41′40″N, 64°13′20″W, quebrada baja en selva más alta de promedio de 15–20 cm de alto, 1,400 m, 16–18 Feb. 1974 (fl), *J. A. A *V. officinali* Warb. maxime similis nervatio et inflorescentiae habitu, sed praecipue androecio breviore et androphoro apicem versus angustato statim dignoscenda.

Tree 20–25 m tall, branchlets robust, subterete, darkly ferruginous tomentose when young (hairs usually sessile or short-stalked, stellate, few-branched, up to 0.5 mm long), soon glabrescent; petioles canaliculate, stout, 3–6 mm long, 1.5–2 mm diam., darkly ferruginous tomentose; leaf blades chartaceous, oblong-lanceolate, 5–12 cm long, 1.8–4.0 cm broad, obtuse at base, acute at apex, glabrescent or sparsely and minutely puberulent beneath (hairs sessile or subsessile, stellate, 4–5-branched); costa shallowly grooved and glabrous above, prominent and tomentellous beneath, secondary nerves 22–26 per side, straight, impressed above, raised-tomentellous beneath, tertiary nerves subparallel, impressed above, obscure beneath. Male inflorescences narrow, once-branched, 6.5–7.5 cm long, peduncle conspicuously flattened, 2.5–3.5 cm long, rachis 5–7 branched, each branch 5–8 mm long; branchlets few, short, with flower clusters sessile toward the apex; vestiture of branchlets and flowers darkly ferruginous tomentose; bracts not seen; flowers arranged in clusters of about 25, pedicels slender, up to 3 mm long. Perianth of male flowers thin, 1.5–3 mm long, 3-lobed nearly to base, the lobes obtuse; androecium 1.2–1.3 mm long, androphore 0.7–0.8 mm long, carnose, slightly narrowed towards the apex, the anthers 3, 0.4–0.5 mm long, obtuse at apex, rounded and abruptly cuneate at base. Female inflorescences and fruits not seen.

Virola steyermarkii has a close affinity with the allopatric *V. officinalis*, particularly in the numerous, close secondary nerves and in the narrow, once-branched male inflorescence, but differs mainly by having a shorter androecium and androphore narrowed from the bottom toward the apex. Further, *V. steyermarkii* is known only from the type locality in Venezuela, very far from the restricted distribution of *V. officinalis* in the Brazilian states of Bahia and Minas Gerais.

The new species is named in honor of the late Julian A. Steyermark for his valuable contributions to the study of the neotropical flora.

I am grateful to the John Simon Guggenheim Memorial Foundation for the fellowship awarded to me in 1982 for continuation of my taxonomic studies of Myristicaceae, to William Leite for drawing the plate, and to Bruce Walker Nelson for reviewing the English translation.

—*William A. Rodrigues, Instituto Nacional de Pesquisas da Amazônia, Caixa Postal 478, 69083 Manaus, Amazonas, Brasil.*

A NEW SPECIES OF *CLITORIA* (LEGUMINOSAE) FROM VENEZUELAN GUAYANA

Two recent collections of a distinctive species of *Clitoria* L. (Leguminosae) were discovered while preparing a treatment of the genus for the *Flora of the Venezuelan Guayana*. This species is assigned to subg. *Bractearia* (Mart. ex Benth.) Fantz sect. *Brachycalyx* Fantz.

Clitoria comprises 60 species distributed primarily within the pantropical–subtropical belt; 49 species are native to the Neotropics. The genus is characterized by showy, resupinate, papilionaceous flowers; infundibular calyx with persistent bracteoles at the base; persistent stipules and stipels; and stalked ovaries with a geniculate, bearded style. Members commonly bear a pubescence of microscopic uncinate (hooked) trichomes best viewed at 20–30×.

Fantz (1979) circumscribed sect. *Brachycalyx* and in 1980 added three new species. Members are characterized by short tubular calyces with minute lobes, inflorescences cauliflorous emerging from denuded nodes preceding the leaves, erect habits (trees or shrubs), and fruits that become weakly convex around the seeds and that are conspicuously depressed transversely between the seeds. Species of this section are distributed from Guyana to central Panama to Ecuador with isolated collections of *Clitoria glaberrima* Pitt. collected as far north as southern Mexico.

Clitoria steyermarkii Fantz, sp. nov. TYPE. Venezuela. Bolívar: cumbre de Cerro Guaiquinima, Salto Río Szczerbanari (Río Carapo), 1–2 km rio arriba del Salto Szczerbanari, 5°44′4″N, 63°41′8″W, 750 m, 20–25 Jan. 1977, *Steyermark et al. 113464* (holotype, F 1878216; isotypes, F 1878213, MO 2769908, US 2821976, VEN).

Frutex ad 2 m altus. Folia trifoliata, foliola coriacea, oblonga-elliptica vel lancea-elliptica, subter pallida, cerifera; stipulae et stipelae lineares, persistentes. Inflorescentia cauliflora, brevissima. Bracteae et bracteolae lineares. Flores parvi, resupinati, albi, margine purpurea. Calyx breviter infundibularis, lobi breves. Stylus ovario duplo longior. Legumen incognitum.

Slender shrub to 2 m tall. Branches 2–5 mm diam., microscopically uncinate and sparsely strigose, becoming glabrous with age; pith hollow. *Leaves* 3-foliate, coriaceous, adaxial surface dull green to bluish green and glabrous, abaxial surface pale green to gray green, ceriferous, glabrous to sparsely strigose on veins; leaflets oblong-elliptic to lance-elliptic, apex with short acumen 0.5–1 cm long, mucronate, base broadly cuneate to nearly rotund, primary lateral veins 7–9 pairs, lamina 5–11 cm long, 2.5–6 cm wide. Petioles 5–8 cm long, subquadrangular, striate to slightly canaliculate at apex, microuncinate and sparsely strigose; rachis 1.5–3 cm long; petiolules subquadrangular, rugose, dark colored, sparsely pubescent, 4–6 mm long. Stipules persistent, linear, acute, striate, strigose apically, 3–4 mm long, 1 mm wide; stipels persistent, shorter than petiolules, linear-subulate, striate, 3–4 mm long, ca. 0.3–0.5 mm wide. *Inflorescences* cauliferous (1–3-fascicled) to 5 mm long, pseudoracemose, nodose, with 4–8 flowers, these paired at nodes, axes microuncinate; pedicels 3–4 mm long. Bracts in 3 series, striate, microuncinate, strigose-pilose apically; inner and middle ones inconspicuous, ovate, acute, ca. 0.4–0.6 mm long, 0.2–0.4 mm wide, outer ones linear, 2–3 mm long, ca. 0.3–0.5 mm wide. Bracteoles linear, acute, striate, microuncinate, 3–5 mm long, ca. 0.3–0.5 mm wide, inserted 1–2 mm below calyx base. *Flowers* resupinate, small, 2.5–3.5 cm long, white with purplish margin and purple venation. Calyx infundibular, 10-nerved, uncinate (trichomes conspicuous at 10–12×), tube 9–11 mm long, 2–3 mm wide at base expanding to 4–6 mm wide at throat, lobes acuminate-deltoid, 2–3 mm long, 1.5–2 mm wide basally, ventral lobe 3–4 mm long. Vexillum microuncinate toward apex and margins, blade complicate, obovate, emarginate, 1.5–3 cm wide, claw 4–6 mm long. Alae extended beyond carina 3–4 mm, blade 9–10 mm long, 4–5 mm wide, claw 12–14 mm long. Carina falcate, blade 6–8 mm long, 3 mm wide, claw 15–18 mm long. Staminal tube falcate apically, 18–21 mm long, free filaments 1–2 mm long; anthers linear, ca.

1.5 mm long, 0.4–0.5 mm wide. Gynophore ca. 2–3 mm long; ovary linear, 7–9 mm long, sericeous with tawny trichomes ca. 0.6–0.8 mm long masking dense uncinate microtrichomes beneath; style dark colored, ca. twice the ovary length, 14–17 mm long, bearded, geniculate 7–8 mm from distal end. *Legume* unknown.

Paratypes. VENEZUELA. BOLÍVAR: cumbre de Cerro Guaiquinima, Salto Río Szczerbanari (Río Carapo), 1–2 km río arriba del Salto Szczerbanari, 5°44′4″N, 63°41′8″W, 750 m, 20–25 Jan. 1977, *Steyermark et al. 113282* (MO 2769907, US 2821975, VEN).

This species is named in honor of Julian A. Steyermark who collected the species and who established the *Flora of the Venezuelan Guayana* project.

KEY TO SPECIES OF SECTION *BRACHYCALYX*

1a. Flowers 4–6 cm long; legume 10–15 mm wide; bracteoles 2–3 mm long.
  2a. Inflorescence 5–22 cm long; staminal tube 27 33 mm long, glabrous; leaflets glabrous above; shrub or treelet, 2–8 m tall (Ecuador) ..... *C. brachystegia* Benth.
  2b. Inflorescence to 2 cm long; staminal tube 23–26 mm long, microuncinate; leaflets hispidulous above; shrub to 2 m tall (Colombia) ..... *C. hermannii* Fantz
1b. Flowers 2.5–4 cm long; legume 16–30 mm wide; bracteoles 3–5 mm long.
  3a. Inflorescence to 0.5 cm long; leaves glabrous or glabrate below; anthers 1–1.5 mm long.
    4a. Leaves membranous, concolorous, nonceriferous; style 11–13 mm long, subequal ovary length; stipules & stipels caducous, 4–7 mm long; tree (Central America to northern Venezuela) ..... *C. glaberrima* Pitt.
    4b. Leaves coriaceous, pale green to gray green and ceriferous below; style 14–17 mm long, ca. twice the ovary length; stipules & stipels persistent, both 3–4 mm long; small shrub (southeastern Venezuela) ..... *C. steyermarkii* Fantz
  3b. Inflorescence 1–7 cm long; leaves conspicuously pubescent below; anthers 1.5–3 mm long.
    5a. Liana; petiolules 5–7 mm long; bracteoles 3–4 mm long; anthers 2.5–3 mm long; leaflets pilose below (western Brazil) ..... *C. froesii* Fantz
    5b. Tree or shrub; petiolules 7–10 mm long; bracteoles 1.5 3 mm long; anthers 1.5 2 mm long; leaflets strigose or velutinous below.
      6a. Calyx cup-shaped, 8–12 mm wide at throat; flowers white; gynophore 6–7 mm long; style geniculate 6–8 mm from distal end (western Guyana and adjacent Brazil) ..... *C. brachycalyx* Harms
      6b. Calyx narrowly infundibular, 5–7 mm wide at throat; flowers dull purple; gynophore 1–3 mm long; style geniculate 3–6 mm from distal end.
        7a. Calyx tube 7–11 mm long, lobes 2–3 mm long; staminal tube 16–22 mm long; keel blade 7–9 mm long, 2–3.5 mm wide; leaflets velutinous below; tree (Venezuela, Colombia) ..... *C. dendrina* Pitt.
        7b. Calyx tube 13–15 mm long, lobes 3–4 mm long; staminal tube 24–28 mm long; keel blade 14–16 mm long, 4–5 mm wide; leaflets strigose below; shrub (Venezuela) ..... *C. canescens* Pitt. ex Fantz

I am grateful to the curators of the herbaria (F, MO, US, VEN) for the loan of specimens and to Julian A. Steyermark and Bruce Holst for assistance on the *Flora of the Venezuelan Guayana* project. Paper No. 11981 of the *Journal Series of the North Carolina Agricultural Research Service*, Raleigh, North Carolina 27695-7643, U.S.A.

A NEW SPECIES OF *CABOMBA* (CABOMBACEAE) FROM TROPICAL AMERICA

The genus *Cabomba* is restricted to the Western Hemisphere, ranging from the eastern United States through Central America and the Caribbean to Argentina. Species of this genus are quite similar in habit, and few morphological characters are useful for distinguishing among them. The only complete taxonomic treatment of *Cabomba*, by Norman Fassett (1953), separated species primarily using characteristics of the perianth and leaf segments. From my fieldwork in tropical America and an examination of much of the material that has been collected from this region, some taxonomically significant characters not employed by Fassett have been discovered. Such characters are the number of leaves per node, stamen number, and seed size and shape. Other differences among taxa for the characters used by Fassett have also been noted.

In applying this enhanced scrutiny to the material included by Fassett in *C. piauhyensis* Gardner (= *C. furcata*[1]), I have become convinced of the existence of two distinct taxa within this entity. Typical *C. piauhyensis* always has whorled leaves at most or all nodes, commonly six (occasionally four or five) stamens, and subglobose seeds. This has been verified using an isotype of Gardner's original collection (*Gardner 2478* US) and is also readily apparent from the original illustration (Gardner, 1844). The distribution of *C. piauhyensis* (*C. furcata*) includes Brazil, northern Bolivia, Venezuela, eastern Colombia, the Guianas, Trinidad, and outlying populations are known from Cuba and Costa Rica as well. A second taxon, which Fassett failed to recognize, has opposite leaves, often three stamens (sometimes four or five or rarely six), and slightly larger subglobose to oval seeds. This taxon occurs from Honduras to western Ecuador and northern Venezuela and in the Greater Antilles. The principal area of sympatry for the two species is northern Venezuela. The second taxon is here described, and a key to all members of *Cabomba* that occur within its range is provided.

Cabomba haynesii Wiersema, sp. nov. TYPE: Panama. Canal Zone: Gamboa, Chagres River, ca. ¼ mi. up river from hyacinth control building near dock, 8 Feb. 1973, *H. Kennedy, C. von Chong & J. Steiner 2323* (holotype, MO; isotypes, UNA, Z).

Folia natantia laminis simplicibus linearibus usque 1.5 cm longis et 1 mm latis; folia submersa opposita dissecta (divisionibus secundariis dichotomis et trichotomis) segmentis terminalibus 0.1–0.4 mm latis; flores plerumque 6–8 mm longi ubi clausi; stamina saepe 3, interdum 4 vel 5, raro 6; carpella 1–3, plerumque 2; semina 1–3, 1.8–2.5 mm longa, 1.2–1.9 mm lata, 1.1–2× longiora quam lata.

Aquatic herbs with creeping rhizomes rooted in substrate and with elongate, distally floating, leafy stems. Floating leaves alternate, opposite or borne opposite submerged leaves, with petioles to 3.5 cm long, the laminae simple, linear, to 1.5 cm long, to 1 mm wide, peltate, entire. Submersed leaves opposite (rarely whorled at some nodes), with petioles to 2.5 cm long, palmately dissected into usually 5–7 primary segments, these with 1–3 additional and mostly dichotomous divisions, except the central 2–3 segments with secondary and often tertiary divisions trichotomous, terminal segments 0.1–0.4 mm wide. Flowers solitary, axillary from the upper nodes, bisexual, radially symmetrical, mostly 6–8 mm long when closed, borne at or above the water surface on peduncles to 5 cm long; sepals 3, white to pink-purple; petals 3, coloration as in sepals, with protruding auricles near base; stamens often 3, sometimes 4 or 5 or rarely 6; carpels 1–3, mostly 2, each tapering to a short style and a spherical terminal stigma, the ovaries superior, the ovules (1?)2–3. Fruits indehiscent, coriaceous, achenelike, or folliclelike; seeds 1–3, 1.8–2.5 mm long, 1.2–1.9 mm broad, 1.1–2 times as long as broad, with longitudinal rows of papillae at maturity.

[1] Communication with Niels Jacobsen and Marian Ørgaard of the Royal Veterinary and Agricultural University, Frederiksberg, Denmark, who have examined the type of *Cabomba furcata* Schultes & Schultes f. (Roemer & Schultes, Syst. Veg. 7(2): 1379. 1830.), indicates that *C. furcata* is the correct name for the species previously known as *C. piauhyensis*.

Habitat and distribution. Submersed in stagnant or gently flowing water to 1 m deep in ditches, ponds, swamps, marshes, rivers, or streams to 1,000 m of altitude. Honduras to western Ecuador and northern Venezuela, and the Greater Antilles.

Additional specimens examined. EL SALVADOR. LA UNIÓN: Laguna Maquigua, 18 km W of La Unión, *Fassett 28633* (WIS), *Standley 20955* (US). HONDURAS. A NEW SPECIES OF *HYPTIS* (LAMIACEAE) FROM THE VENEZUELAN GUAYANA

While examining collections of Lamiaceae for the *Flora of the Venezuelan Guayana*, I encountered a single gathering of a *Hyptis* species that was unfamiliar to me. It was surprising to find a new *Hyptis* species at an altitude of 120–150 m in northern South America.

Although clearly belonging to sect. *Hyptis*, it differs from all other known species in its elongate, interrupted, pseudospicate inflorescences composed of small sessile capitula and situated in the axils of much-reduced bracts. The new species is also remarkable for its almost sessile leaves, the petiole apparently never more than 2 mm long. In this respect, it recalls *H. vilis* Kunth & Bouché, from Central America and northern Venezuela but differs in floral characters and in leaf shape, and by having sessile rather than long-pedunculate capitula. The lack of a ring of hairs in the calyx tube places *H. guanchezii* in subsect. *Marrubiastrae* Benth., along with *H. parkeri* Benth., which is also found in the Territorio Federal Amazonas.

Hyptis guanchezii is named for the collector and discoverer Francisco Guánchez.

Hyptis guanchezii *R. Harley*, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Depto. Atures, bosque-laja en Cerro Uchonhua (lengua Piaroa), a unos 5 km N del casério San Pedro de Cataniapo (en lugar quemado durante la sequia de 1979), a unos 60 km al SE de Puerto Ayacucho, 05°41′N, 67°11′W, 120–150 m, 9 Nov. 1980, *Guánchez 365* (holotype, VEN; isotypes, K, TFAV). Figure 1.

Ab aliis speciebus sectionis Hyptidis foliis subsessilibus vel petiolis usque 2 mm longis, lamina basim truncata vel leniter subcordata, inflorescentia spiciformi interrupta capitulis sessilibus in axillis bracteis deminutis subtentis, differt.

Erect herb to 80 cm high, with slender purple-tinged stems branching from a central rootstock. Stems quadrangular with coarse, spreading villous hairs below, these sparser and more slender above, the nodes densely tufted with whitish, antrorse hairs. Leaves 3.5–7.5 × 2.0–3.2 cm, markedly decreasing in size above and often shorter than the internodes, ovate-lanceolate to narrowly ovate with acute apex and narrowing to a truncate or weakly cordate base; upper surface of lamina appearing dark green, villous with scattered rather broad-based hairs, the veins weakly impressed; lower surface paler, villous with weak hairs restricted to the rather prominent veins and margin, glabrous between the veins and with sunken sessile glands; margin coarsely and bluntly serrate; petioles 1–2 mm, the upper leaves often appearing almost sessile. Inflorescence spiciform, 10–15 cm long, composed of opposite sessile capitula in the axils of inconspicuous bracts, the lower internodes usually 5–6 cm long. Bracts up to 4–6 mm long (the upper bracts shorter), lanceolate to ovate-acuminate, with broadened base and somewhat recurved margin, midrib prominent abaxially. Capitula 10–12 mm diam., with an involucre of narrowly lanceolate, curved bracteoles up to 5 × 1 mm, these glabrous with the midrib prominent beneath. Flowers subsessile, surrounded at base by dense tuft of long, silky, white (pale brown in herbarium material) hairs. Calyx tubular, at anthesis ca. 4 mm long, the tube 2–2.5 mm, glabrous throughout; calyx teeth 1.75–2 mm long, narrowly deltoid-lanceolate, ciliate with long-acuminate apex. Corolla 5–6 mm long, white, the tube ca. 4.5 mm long; stylopodium absent. Ripe nutlets not seen.

I acknowledge Julian Steyermark's vision in conceiving the idea of a *Flora of the Venezuelan Guayana*, which helped turn my attention to this floristically rich area with its particularly interesting phytogeographical patterns in the Lamiaceae.

NEW COMBINATIONS IN *SORGHASTRUM* (POACEAE: ANDROPOGONEAE)

Nash (1901:71) separated *Sorghastrum* from *Sorghum* Moench on the basis of the reduction of the pedicellate spikelets to simple pedicels in *Sorghastrum*. Morphological, anatomical, and cytological data (Davila, in prep.) support Nash's conclusion and reinforce the generic recognition of *Sorghastrum*. Davila (1988) recognized 15 American and two African species of *Sorghastrum*. Two new combinations in this genus are presented below.

Sorghastrum balansae (Hackel) Davila, comb. nov. *Sorghum balansae* Hackel, Fl. Bras. 2(3): 277. 1883. TYPE: Paraguay: *Balansa 209a* (holotype, P).

Sorghastrum incompletum (Presl) Nash var. **bipennatum** (Hackel) Davila, comb. nov. *Andropogon bipennatus* Hackel, Androp. Nov. Fl. 68(8): 142. 1885. TYPE: Central African Republic: Djur and Scriba ghattas, *Schweinfurth 2486* (holotype, US).

PASSIFLORA MALLETII, A NEW SPECIES IN SECTION *DECALOBA* (PASSIFLORACEAE) FROM MESOAMERICA

A number of undescribed species of passionflower have been found during a revision of the Passifloraceae for the *Flora Mesoamericana* project (in press); most of them are in the small-flowered subgenus *Plectostemma* Masters. Newly described here is one such species; it is restricted to Panama and known from three recent collections.

Passiflora malletii J. MacDougal, sp. nov. TYPE: Panama. Panamá: near Cerro Jefe, 3 mi. along road past Alto Pacora toward Cerro Brewster, 9°15′N, 79°25′W, 700–750 m, 19 June 1988, *G. McPherson 12612A* (holotype, MO; isotype, PMA). Figure 1.

Passiflora pubescens scandens; petioli eglandulosi; folia eglandulosa integra acuta vel acuminata, vel raro trilobata, marginibus integris; bracteae lineares vel fusiformes vel obtrullatae, integrae vel trifidae, (3.5)4 7 × (0.3–) 0.7 2(3) mm; flores parvi subvirides vel pallido-viridiflavi, perianthiis ad basim purpurascentibus; coronae filamenta biseriata, filamentis exterioribus filiformibus 3.8–5 mm longis; operculum plicatum purpureum setulosum; androgynophorum 2.5(–3) mm longum; ovarium dense pubescens pilosum; bacca atropurpurea; semina 5–6(–7)-sulcata.

Vine 3–5 m, densely short-pubescent to pilosulous throughout. Stems subangulate or subflattened, substriate. Stipules (3–)5–8 × (0.3–)0.6–1 mm, linear to linear-lanceolate, sometimes slightly falcate; petioles eglandular; laminas (1.5–)4–10 × (0.8–)1.5–6 cm, entire, not variegated, ovate (rarely ovate-oblong), unlobed or occasionally 2–3 lobed (if lobed then usually unlobed leaves also present on the branch), the leaves of determinate axillary branches usually unlobed, the lateral lobes if present acute to acuminate, the central lobe acuminate (to acute); laminar nectaries absent. Inflorescence often present, of determinate, short, axillary shoots with reduced or no leaves. Peduncles 1(–2) per node, 0.6–1.4 cm long, uniflorous; bracts (3.5–)4–7 × (0.3–)0.7–2(–3) mm, linear, fusiform, oblanceolate, or obtrullate, entire or deeply 3-toothed to 3-cleft. Flowers pale to light yellow-green, slightly flushed purplish; floral stipe up to 0.5 mm long; sepals 8–10 × 4.2–5 mm, with no apical projection; petals 1–2 mm long (or obsolete?); coronal filaments in 2 series, the outer series 3.8–5 mm long, filiform, pale greenish yellow or greenish white, basally purplish?, the inner series ca. 3.5 mm long, capitellate, whitish with purplish apices; operculum 1.5 mm long, membranous, plicate, sparsely setose below the apex, purplish; staminal filaments connate 2.5(–3) mm along androgynophore, the free portions ca. 4 mm long; ovary densely pilose, dark green. Fruit 1.3–1.8 cm diam., subglobose, (dark green to) purplish black, estipitate; arils unknown; seeds 2.8–3.1(–3.3) × 1.9–2.1 mm, transversely sulcate with 5–6(–7) sulci, the ridges slightly rugulose.

Habitat and distribution. The one field observation by Mallet and the three collections are from 300–750 m at edges of tropical wet forest and premontane wet forest, within 25 km of each other in central Panama. The label on the type describes the locality as "Pacific slope near divide, rich wet forest."

Name. The specific epithet honors the ecologist Dr. James Mallet, whose specialty is the Heliconiine butterflies that feed on Passifloraceae. He observed this species along the Llano–Cartí road in March 1982, made field notes about the plant, sent living collections to the University of Texas at Austin for study (which died), and pointed out (in litt.) that it was apparently undescribed. He has made numerous and detailed observations on the Passifloraceae and realized that a number of species he encountered were new. By kindly allowing free access to his field books, his detailed notes have enhanced the accuracy of the revision for *Flora Mesoamericana* and contributed much to our understanding of *Passiflora*.

Additional specimens examined. PANAMA. PANAMÁ: El Llano to Cartí road, 9.3 km N of Panamerican Hwy., 8 June 1977, *Folsom 3601* (MO); El Llano–Cartí road, 9 mi. from Panamerican Hwy., 9°16′N, 78°57′W, ca. 300 m, 28 July 1983, *J. S. Miller et al. 851* (BM, MEXU, MO, PMA).

FIGURE 1. *Passiflora malletii*, composite drawing from *J. S. Miller et al. 851* and *Folsom 3601*.—A. Habit.—B. Bracts.—C. Stipule.—D. Seed.

Passiflora malletii is a member of subg. *Plectostemma* Masters sect. *Decaloba* DC. as revealed by the small flowers with biseriate filamentous corona and plicate operculum, small free bracts, narrow stipules, and transversely sulcate seeds. Within sect. *Decaloba* it belongs with the species group that includes *P. sexflora* A. L. Juss., *P. rugosissima* Killip, *P. porphyretica* Masters, and two new

species from Mexico. From these it is remarkably distinguished by its mostly unlobed, sharply pointed leaves, an evidently derived condition. Mallet's field notes describe the stem as strongly flattened, suggestive of an unusual phyllotaxy for the family, but the dried specimens of the other collectors appear to be subangulate to partially flattened. The phyllotaxy is not clear because of deformation of the stems in drying; both $\frac{2}{5}$ and $\frac{1}{2}$ are known in the related species of this group.

The flowers of the new species are notable for their short androgynophore and very reduced petals. The sparsely setulose operculum is also distinctive since the floral parts are only rarely pubescent in this genus. The peduncles are uniflorous and the flowers are generally crowded on determinate axillary branches, much like its close relative *P. porphyretica*.

The seeds of nearly all of the species of sect. *Decaloba* are probably bird dispersed, but observations are few. The label on *J. S. Miller et al. 851* notes "fruit green and being eaten by toucanettes." I believe the mature fruits to be purplish black because in this collection the pericarps turned black during the process of preparing the specimen, a phenomenon commonly seen with nearly mature fruits in this section. In most species of *Passiflora* the seeds and arils mature before the pericarp changes color (pers. obs.). It thus appears that the birds were eating submature fruit, probably with sweet mature arils.

The Missouri Botanical Garden, with a grant from the Jessie Smith Noyes Foundation, generously funded my postdoctoral research. John Myers prepared the illustration.

—John M. MacDougal, Missouri Botanical Garden, P.O. Box 299, St. Louis, Missouri 63166-0299, U.S.A.

A NEW COMBINATION IN *OCOTEA* (LAURACEAE)

Nees (1836) described *Nectandra arnottiana* in his *Systema Laurinarum* and cited only a specimen from the Arnott Herbarium which is now incorporated in the Herbarium of the Royal Botanic Garden, Edinburgh (E). This specimen has not been seen by later botanists working on Lauraceae, who treated the name incorrectly. Meissner (1864) treated *N. arnottiana* as a variety of *Nectandra laurel* Nees and stated that he did so only guided by Nees's description. Mez (1889) accepted *N. arnottiana* as a valid species and treated *Pleurothyrium chrysothyrsus* Meissner as a synonym of it. He cited only *Mathews 3031* (K, BM), the type of *P. chrysothyrsus*, under *N. arnottiana* and obviously had not seen the specimen from the Arnott Herbarium. I have now seen the Edinburgh specimen annotated by Nees as *N. arnottiana*. This specimen is *Mathews 1429*. Meissner (1864) recognized a duplicate of *Mathews 1429* in Kew as an undescribed species and made it the type of his *Pleurothyrium ferrugineum*, a species up to now known as *Ocotea ferruginea* (Meissner) Mez. But because the Nees epithet has priority, I transfer it to *Ocotea* and present the synonymy for the resulting combination, with the Meissner name in synonymy.

Ocotea arnottiana (Nees) van der Werff, comb. nov. BASIONYM: *Nectandra arnottiana* Nees, Syst. Laurin. 289. 1836; *Nectandra laurel* Nees var. *arnottiana* (Nees) Meissner, DC. Prodr. 15(1): 147. 1864. TYPE: *Mathews 1429* (holotype, E).

Pleurothyrium ferrugineum Meissner, DC. Prodr. 15(1): 169. 1864, superfluous name for *N. arnottiana*; typified by different specimen from same collection number; *Ocotea ferruginea* (Meissner) Mez, Jahrb. Bot. Garten Berlin 5: 265, 1889. TYPE: *Mathews 1429* (holotype, K).

Duplicates of *Mathews 1429* have also been reported from BM, G, OXF, and P; these are all isotypes of *Ocotea arnottiana* (Nees) van der Werff. Excluded from the synonymy is *Nectandra arnottiana* sensu Mez, non Nees, Jahrb. Bot. Garten Berlin 5: 402, 1889. Mez based his description on *Mathews 3031*, the only collection cited, and his description of leaves and flowers does not apply to *Ocotea arnottiana*.

Ocotea arnottiana is known to me from Andean cloud forests at 2,000–3,000 m in northern Peru and southern Ecuador. Bernardi (1975) placed *Ocotea steyermarkiana* Allen in synonymy under *O. ferruginea* and identified several collections from Venezuelan Guayana as *O. ferruginea*. However, I consider these Venezuelan collections distinct from *O. arnottiana*; their correct name is *Rhodostemonodaphne steyermarkiana* (Allen) van der Werff. Similar coriaceous leaves with raised reticulation and a dense tomentum on the lower leaf surface, which misled Bernardi, occur in several unrelated, montane species of Lauraceae and are probably a habitat adaptation. Meissner (1864) already noted the strong similarity between "*Pleurothyrium ferrugineum*" (= *Ocotea arnottiana*) and *Persea ferruginea* HBK; and an as yet undescribed species of *Ocotea* (not related to *O. arnottiana*) from high elevation cloud forests in Ecuador and Colombia also has these characteristics.

I thank the curator of E for the loan of neotropical Lauraceae.

SISYMBRIUM AREQUIPANUM (BRASSICACEAE), A NEW SPECIES FROM PERU

The Brassicaceae (Cruciferae) of Peru were treated by Macbride (1938) more than half a century ago. Many new taxa and nomenclatural changes have since been proposed (see for example, Al-Shehbaz, 1989a, b; Khanna & Rollins, 1965). The family as represented in South America needs to be revised, and many undescribed taxa, particularly in the genera *Draba* L., *Lepidium* L., and *Sisymbrium* L., should be accounted for. The present writer is presently working on *Draba* in South America as a first step toward achieving that goal.

Sisymbrium arequipanum Al-Shehbaz, named after Depto. Arequipa (Peru), to which it is apparently endemic, is somewhat isolated morphologically from all of the Peruvian species of *Sisymbrium*. It is easily distinguished by having narrowly linear-lanceolate, remotely dentate basal leaves, auriculate linear-lanceolate cauline leaves, a few small flowers, and straight, terete fruits on short, ascending, straight pedicels. The species resembles superficially members of *Arabis* L., but this genus does not occur anywhere in Central and South America, and it always has flattened fruits.

Sisymbrium arequipanum Al-Shehbaz, sp. nov. TYPE: Peru. Depto. Arequipa: Pichu Pichu, sandy hillside, 5 Jan. 1937, 13,500 ft. [ca. 4,423 m], *Dora Stafford 674* (holotype, F; photo, GH). Figure 1.

Herba perenna, caulibus erectis glabris, 7–21 cm longis; folia basalia petiolata, angusti lineari-lanceolata, remoti dentata, ciliata, attenuata, 3.5–14 cm longa, 2–8 mm lata; folia caulina auriculata, lineari-lanceolata, integra; racemi ebracteati, pedicelli fructiferibus recti, crassi, adscendentibus, 2–6 mm longi; sepala erecta, oblonga, sparse hirsuta, 3–3.5 mm longa; petala alba, spathulata, 3.5–4.5 mm longa, 1.2–1.4 mm lata; siliquae teretae, linearae, 1.5–4 cm longae, ca. 1.5 mm latae; stylus 0.4–0.7 mm longis; semina immatura uniseriata.

Perrenial herbs with a slender to thick caudex covered with petiolar remains of previous years. Stems simple, erect, glabrous, 1 or few from the caudex, 7–21 cm high. Basal leaves petiolate, narrowly linear-lanceolate, 3.5–14 cm long, 2–8 mm wide, remotely dentate, ciliate, acute to acuminate at apex, attenuate at base, sparsely to densely hirsute on both surfaces, the trichomes simple, straight, 0.3–0.6 mm long; petioles slender, ciliate, flattened and broadened at base. Cauline leaves few, sessile, auriculate, linear-lanceolate, 1.5–3 cm long, 2–2.5 mm wide, entire, ciliate. Inflorescence an ebracteate, few-flowered, corymbose raceme, elongated considerably in fruit; fruiting pedicels thick, ascending, straight, sparsely pubescent, 2–6 mm long. Sepals erect, oblong, 3–3.5 mm long, 1–1.3 mm wide, nonsaccate at base, scarious at margin, sparsely hirsute. Petals white, spatulate, 3.5–4.5 mm long, 1.2–1.4 mm wide, rounded at apex, attenuate at base to a claw ca. 2 mm long. Filaments erect, white, ca. 3 mm long; anthers oblong, ca. 0.8 mm long. Nectar glands confluent, subtending the bases of filaments. Fruits ascending, linear, terete, obscurely torulose, 1.5–4 cm long, ca. 1.5 mm wide; valves glabrous, with a conspicuous midvein; septum complete; style 0.4–0.7 mm long; stigma slightly 2-lobed. Immature seeds uniseriate, ca. 2.4 × 1.2 mm.

Additional specimen examined. PERU. DEPTO. AREQUIPA: SW slope of Nevado Chachani, rocky quebrada with steep slopes, 3,950 m, 3 Nov. 1963, *Richard M. Straw 2326* (US).

The holotype of *Sisymbrium arequipanum* differs from the paratype in being sparsely instead of densely hirsute. The two collections are otherwise very similar.

I am most grateful to the directors and curators of the Field Museum and the Smithsonian Institution for the loan of specimens. I thank Neil A. Harriman for his critical review of the manuscript and Barbara Nimblett for typing the manuscript.

INGA NEBLINENSIS (LEGUMINOSAE–MIMOSOIDEAE), UNA NUEVA ESPECIE DEL SUR DE VENEZUELA

English Summary

Inga neblinensis (Leguminosae) is named and described from Venezuela.

Una serie de colecciones recientes de la base y las laderas de Cerro de la Neblina en Territorio Federal Amazonas, Venezuela, ha confirmado la presencia de una nueva especie de *Inga*, la cual se describe a continuación.

Inga neblinensis Cárdenas & De Martino, sp. nov. TIPO: Venezuela. Territorio Federal Amazonas: Departamento Río Negro; gravelly banks of large island in Río Mawarinuma just above Neblina Base Camp, ca. 160 m, 00°50′N, 66°10′W, small tree, flowers yellow, 3 Dec. 1984, *R. Kral 71954* (holotipo, MY). Figura 1.

Arbor ramis glabris, striatis vel costatis, fuscis. Foliorum rhachi alata; foliola plerumque 3-juga, elliptica, glabra vel subglabra, nitida, 2.6–20 cm longa, 1–6.5 cm lata, apice acuta, basi cuneato-rotundata. Flores magni, calyce tubuloso, 5-dentato, 5–11 mm longo; corolla tubulosa, 5-lobata, 1.3–2.2 cm longa; staminibus numerosis, 4–5.4 cm longis; pistillo 3.5–5.2 cm longo. Legumen compressum, nitidum, fuscum, nervis transversis praeditum, basi rotundatum, apice cuspidatum.

Arbusto o árbol pequeño 3–8 m alto. Ramas flexuosas, glabras, estriadas o costilladas, castaño-ennegrecidas; lenticelas dispuestas longitudinalmente, generalmente de color más claro que el resto de la superficie de la rama. Hojas con 2–4 pares de folíolos, más comúnmente 3 pares, el distal siempre más grande; estípulas subuladas o lanceoladas, estriadas, 3–6 mm largo, 1–1.5 mm ancho, glabras o las márgenes pubescentes; pecíolo desnudo o alado, pubescente, 4–17 mm largo (incluye el pulvínulo); raquis alado, 2–7.8 cm largo, ala 2–10 mm ancho (incluye el raquis), ancha y cordada en el ápice, angostada hacia la base; peciolulo antrorso-pubérulo, ennegrecido como el pulvínulo, 2–2.5 mm largo, 1–2 mm ancho, articulado con el raquis; folíolos elípticos, 2.6–20 cm largo, 1–6.5 cm ancho, glabros o subglabros, nítidos por ambas caras, arriba castaño-ennegrecidos, abajo pardos, nervadura pinnada sobresaliente, el envés conspicuamente reticulado, margen entero, ondulado, glabro o antrorso-aplicado, base cuneado-redondeada, ápice agudo o algo obtuso, a veces acuminado, la punta mucronulada; glándula entre cada par de folíolos, subglobular u ovoide, cupuliforme, levantada sobre la superficie, castaño-ennegrecida, adentro casi negra, 1.3–2.8 mm diámetro. Flores en racimos acortados corimbiformes; pedúnculos antrorso-pubérulos, 1–2 en las axilas de las hojas, 2–4.2 cm largo, 1 mm diámetro; brácteas caedizas, 2–6 mm largo, 0.1–1.5 mm ancho, pedicelos pubérulos, 1–2 mm largo, 0.5–1.5 mm diámetro; cáliz tubular, pubérulo, nervado, 5-dentado, 5–11 mm largo, 1.5–3 mm diámetro, dientes irregulares; corola tubulosa, tomentosa a escaso pubérula, nervada, 5-lobulada, 1.3–2.2 cm largo, 1–3 mm diámetro, abajo unida al tubo estaminal en una distancia de 2–4 mm, lóbulos 2–5 mm, profundos, márgenes involutos; estambres numerosos (más de 50), 4–5.4 cm largo, tubo estaminal exerto o incluso, 2–2.6 cm largo; granos de polen en políades; pistilo 3.5–5.2 cm largo, ovario sésil, glabro o corto pubérulo, 2–2.5 mm largo, 0.2–0.9 mm diámetro. Legumbre aplanada, 10–13.3 cm largo, 2.1–2.5 cm ancho, 2–3 mm grueso, base redondeada, ápice cuspidado, superficie brillante, castaño-ennegrecida, con numerosos nervios transversales.

Paratipos. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Departamento Río Negro, Neblina Base Camp, Río Mawarinuma, periodically flooded forest along river, 140 m, 00°50′N, 66°10′W, 21 Feb. 1985 (fr), *Boom & Weitzman 5930* (MY); Neblina Base Camp on the Río Mawarinuma, 00°50′N, 66°10′W, ca. 140 m, 17 July 1984 (fr inmaduro), *Davidse & Miller 27438* (MY);

FIGURA 1. *Inga neblinensis* (*Kral 71954*) –a. Rama florífera.—b. Flor, corte longitudinal.

margins of Río Mawarinuma below Cerro Neblina Base Camp, 140 m, 00°50′N, 66°11′W, frequently inundated bamboo swamp forest, 4 May 1984 (fl), *Gentry & Stein 47172* (MY); near Cerro de la Neblina, Base Camp, Río Mawarinuma, 140 m, 00°50′N, 66°55′W, 5 Feb. 1984, (fr inmaduro), *Liesner 15664* (MY); Cerro de la Neblina Camp IV, 15 km NNE of Pico Phelps, N branch of river in canyon, 780 m, 00°51′N, 65°57′W, 15–18 Mar. 1984 (fr inmaduro, restos de fl), *Liesner 16710* (MY); along Cañon Grande E of Cumbre Camp, Cerro de la Neblina, Río Yatua, 1,100 m, 24 Nov. 1957 (fl), *Maguire, Wurdack & Maguire 42223* (VEN); tropical lowland evergreen forest along gravelly and silty banks of river, along Río Baria (= Río Mawarinuma) just upstream from Base Camp, SW side of Cerro de la Neblina, 140 m, 00°49′50″N, 66°09′40″W, 16 Feb. 1985 (fr inmaduro), *Nee 30876*

(MY); ca. 2 km S of Base Camp, alluvial and upland forests along Mawarinuma River, 140 m, 00°50′N, 66°10′W, 11 Feb. 1984 (fl), *Thomas & Plowman 3008* (MY); along Río Mawarinuma, 2–6 km E of base camp, between base camp and "Puerto Chimo," 160 m 00°50′N, 66°08′W, 26 Apr. 1984 (fl), *Thomas 3212* (MY); along Río Mawarinuma, at "Puerto Chimo" camp, ca. 6 km E of base camp, 170 m, 00°50′N, 66°07′W, 23 April 1984 (fl), *Thomas 3224* (MY).

Inga neblinensis pertenece a la sección *Pseudinga* Benth. Se caracteriza por sus hojas glabras, nítidas, raquis alado, flores grandes amarillentas y por el color castaño-ennegrecido de la planta (en muestras de herbario). Solamente se ha localizado en el sur del Territorio Federal Amazonas, en el Cerro de la Neblina.

—*Lourdes Cárdenas & Giovanna De Martino, Instituto de Botánica Agrícola, Facultad de Agronomia, Universidad Central de Venezuela, Apartado 4579, Maracay 2101, Venezuela.*

REDISCOVERY OF *TETRAMOLOPIUM ARENARIUM* SUBSP. *ARENARIUM* VAR. *ARENARIUM* (ASTERACEAE: ASTEREAE) ON THE POHAKULOA TRAINING AREA, HAWAII

The initial step in the U.S. Army's Land Condition Trend Analysis Program (LCTA) is to conduct a comprehensive floristic and vegetation inventory of each installation. One of the first group of installations to be inventoried was the Pohakuloa Training Area (PTA) on the Island of Hawaii, Hawaii (Fig. 1). Pohakuloa Training Area is a 44,100-ha area located in the saddle between Mauna Loa and Mauna Kea. Approximately half of the installation is ordnance impact area. Because of the rough terrain and inaccessibility of much of the area, only about 4,100 ha are used for infantry, artillery, and tracked-vehicle maneuvers.

Three endangered plant species have been identified previously from PTA (Herbst & Fay, 1979): *Haplostachys haplostachya* (A. Gray) St. John var. *angustifolia* (Sherff) St. John (Lamiaceae), *Stenogyne angustifolia* A. Gray var. *angustifolia* (Lamiaceae), and *Lipochaeta venosa* Sherff (Asteraceae). The species of Lamiaceae were thought to be extinct until their rediscovery on PTA (Ayensu & DeFilipps, 1978; Herbst & Fay, 1979). All three of these species occur in a designated endangered plants habitat (approximately 1,600 ha) on the northwest side of PTA within Kipuka Kalawamauna (Fig. 1). This kipuka is a vegetated older lava flow isolated by newer, sparsely vegetated, or barren lava flows. The elevation of the area is approximately 1,545 m. The kipuka receives about 380 mm of precipitation annually.

During the LCTA survey of the vegetation at PTA, *Tetramolopium arenarium* (A. Gray) Hillebr. subsp. *arenarium* var. *arenarium* (Asteraceae: Astereae) was collected by P. Douglas (*Douglas 3191*) (Fig. 2). Ayensu & DeFilipps (1978) and Lowery (1986) reported this taxon as presumably extinct because no collections had been made since the late 1800s. The only previously known localities for this taxon were Puu Hualalai and Nohonao Hae (near Waimea) on Hawaii and Kula, East Maui (Lowery, 1986). A botanical survey conducted in 1977 as supporting documentation for an environmental impact statement for PTA listed *T. arenarium* (Lawrence Hirai, pers. comm.). We have been unable to locate any voucher specimens for this reported collection.

Douglas 3191 was collected in the endangered plants habitat, near the three endangered plant species. The population of *Tetramolopium* covers an area about 200 m by 60 m and is bisected by an unpaved road. One part of the population grows about 20 m east of the road. When last observed, it consisted of 33 robust individuals. The other portion, with 81 adult plants and 14 juvenile or seedling plants, occurs approximately 80 m west of the road. Consequently, the two portions are about 10 m apart. Fifteen dead individuals were found in the larger portion of the population. The cause of death of these plants is unknown. The occurrence of juvenile or seedling plants indicates that viable seed is being produced and that environmental conditions necessary for seed germination and seedling establishment occur periodically. Mature plants were observed flowering in January, April, and August.

The collection was made in a shrubland dominated by *Dodonaea viscosa* Jacq., *Dubautia linearis* (Gaud.) D. Keck, and *Sophora chrysophylla* (Salisb.) Seem. A weedy, introduced grass (*Pennisetum setaceum* (Forssk.) Chiov.) is aggressively expanding into the area. The *Tetramolopium* population occurs on a mesic ridge that runs west-northwest. The soil type at this site is rockland (rRO) (USDA, 1973).

Tetramolopium arenarium is a member of sect. *Sandwicense* Lowery, which is composed of gynomonoecious, upright shrubs with corymbose-paniculate heads, narrowly funnelform disk corollas, and fewer than 15 disk florets per head (Lowery & Crawford, 1985; Lowery, 1986). This section

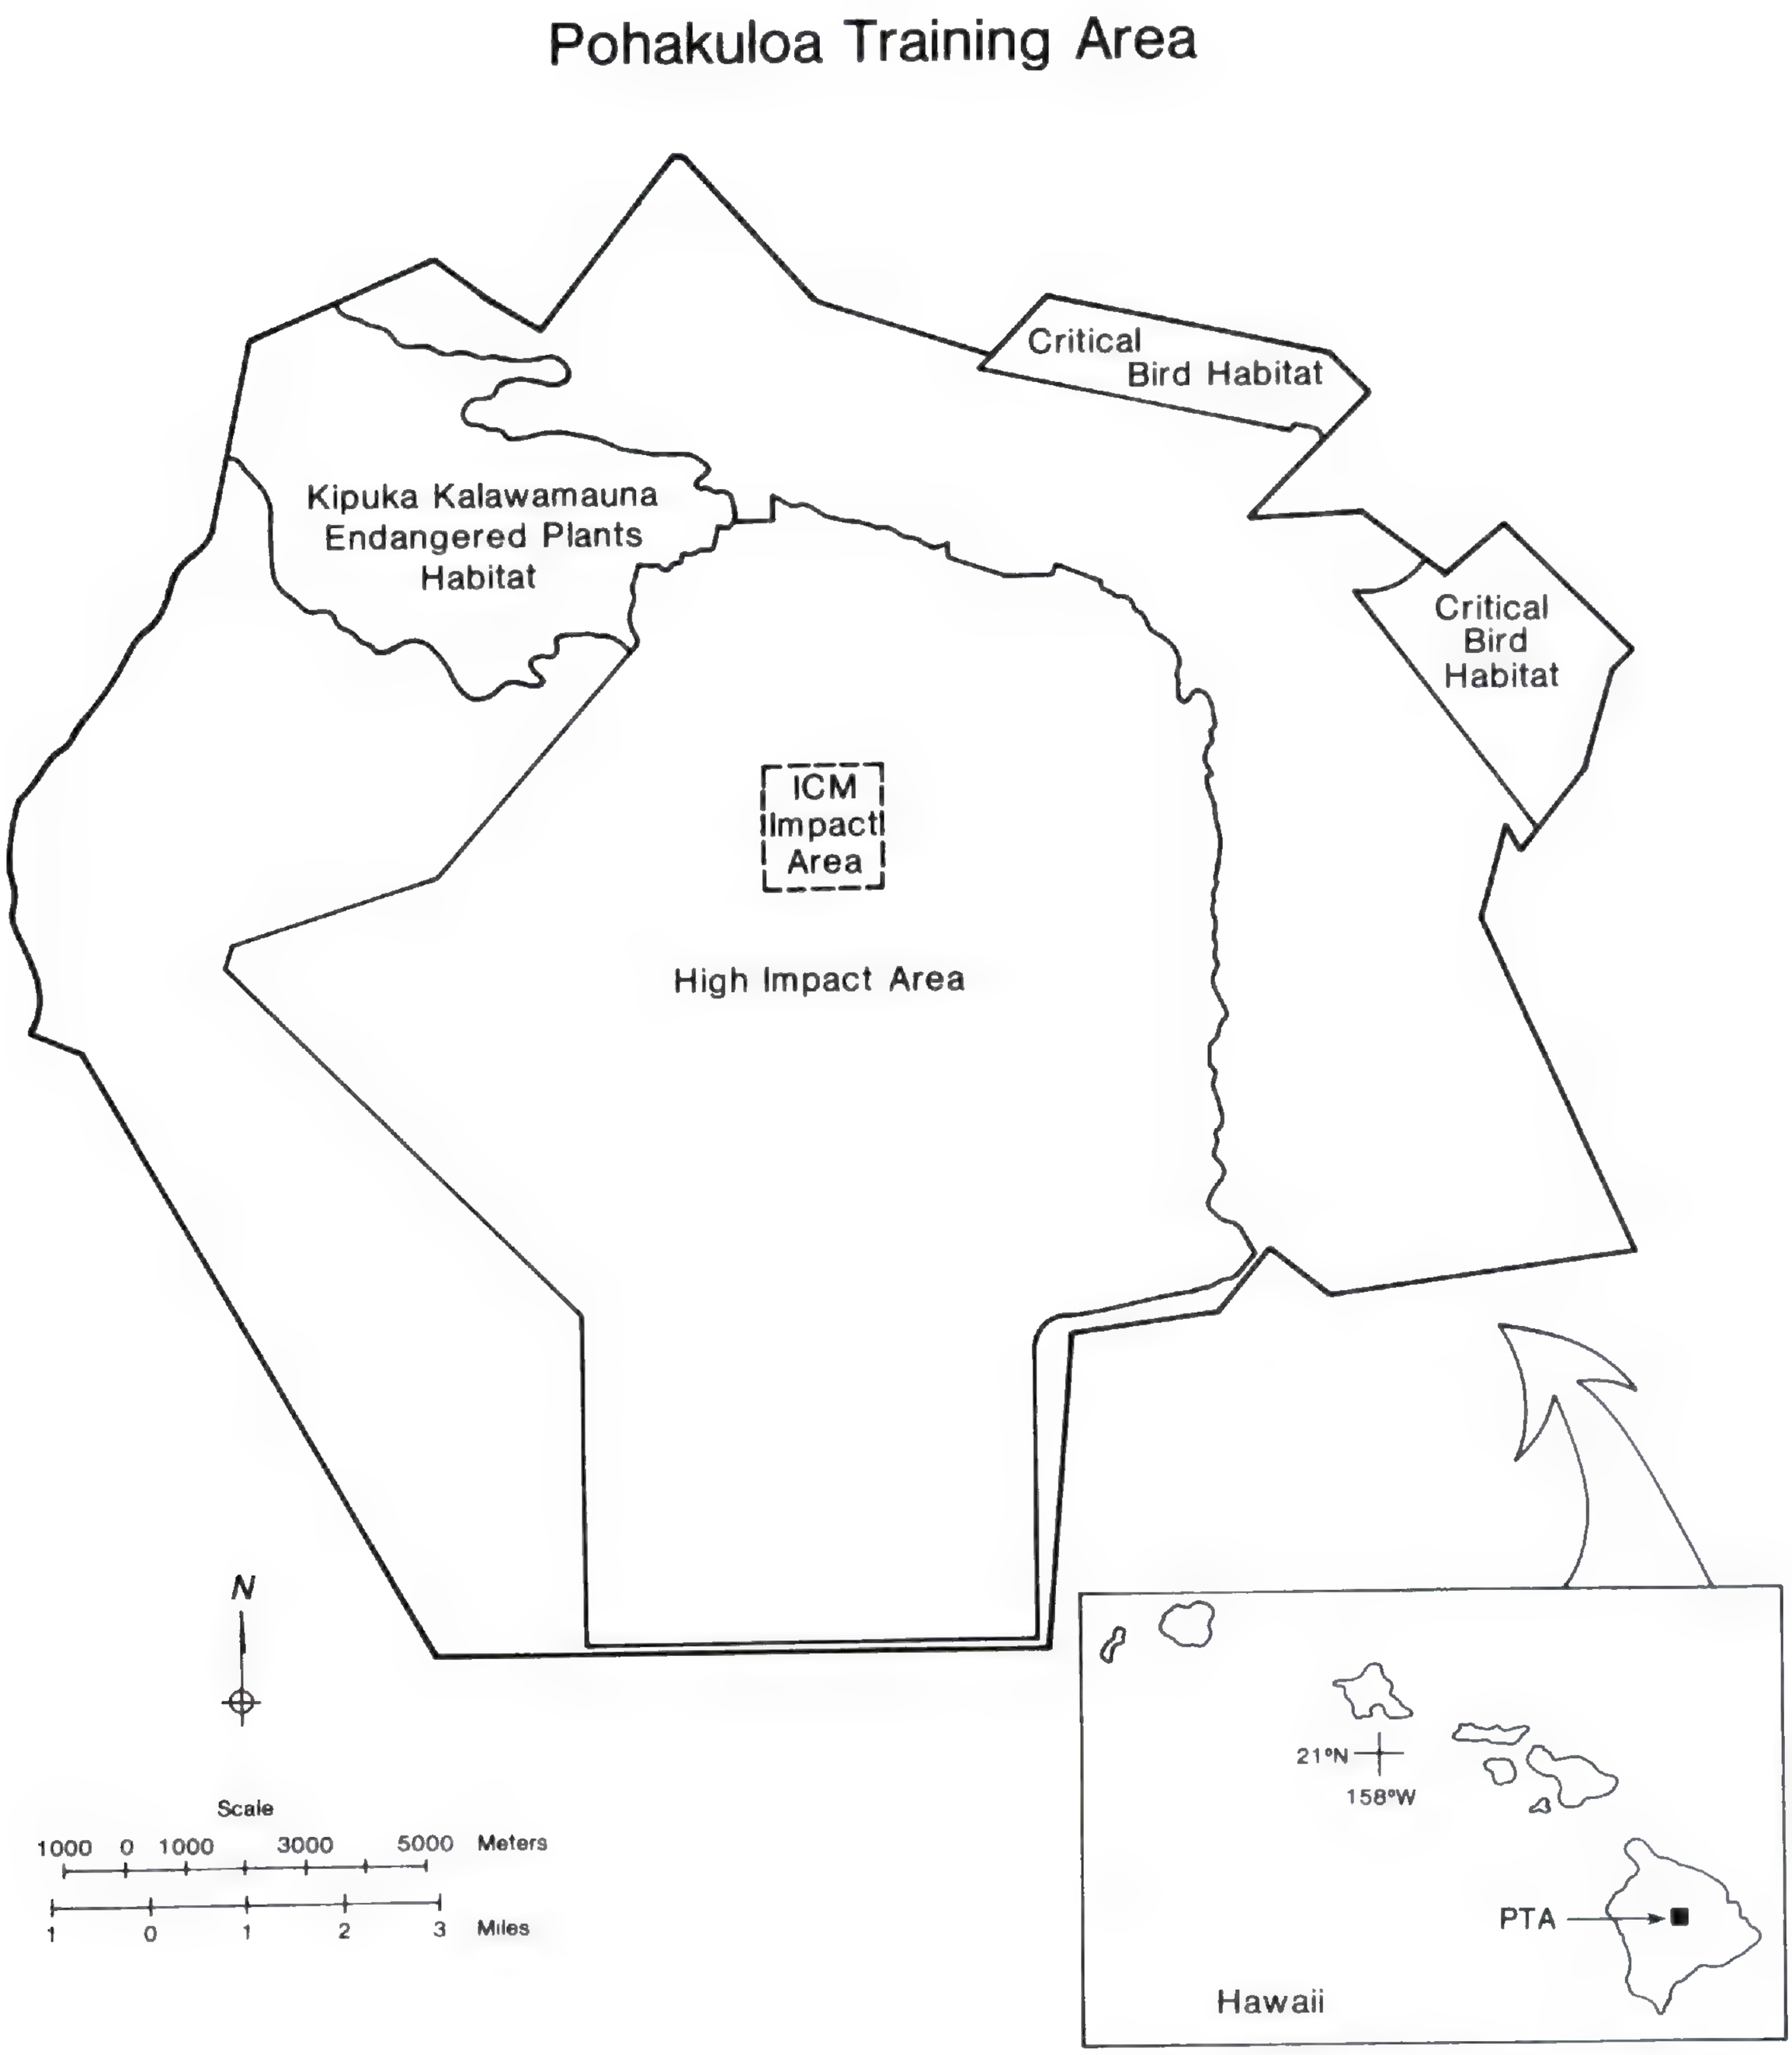

FIGURE 1. Map of Pohakuloa Training Area, Island of Hawaii, Hawaii, showing the extent of the ordnance impact area, and locations of the Kipuka Kalawamauna Endangered Plants Habitat and Critical Bird Habitat (Palila, *Loxioides bailleui* Oustalet).

also includes *T. consanguineum* (A. Gray) Hillebr., *T. conyzoides* (A. Gray) Hillebr., and *T. lepidotum* (Less.) Sherff. Of the four species in the sect. *Sandwicense*, two have been considered extinct: *T. arenarium* and *T. conyzoides* (Ayensu & DeFilipps, 1978; Lowery, 1986). The other two species have extinct infraspecific taxa (Lowery, 1986).

Tetramolopium consanguineum never has hirsute or pilose leaves (*Douglas 3191* has densely and evenly hirsute leaves). *Tetramolopium conyzoides* has 1–3 disk florets per head (*Douglas 3191* has 5–9 disk florets per head). *Tetramolopium lepidotum* has glandular punctate leaves (*Douglas 3191* has glandular but not punctate

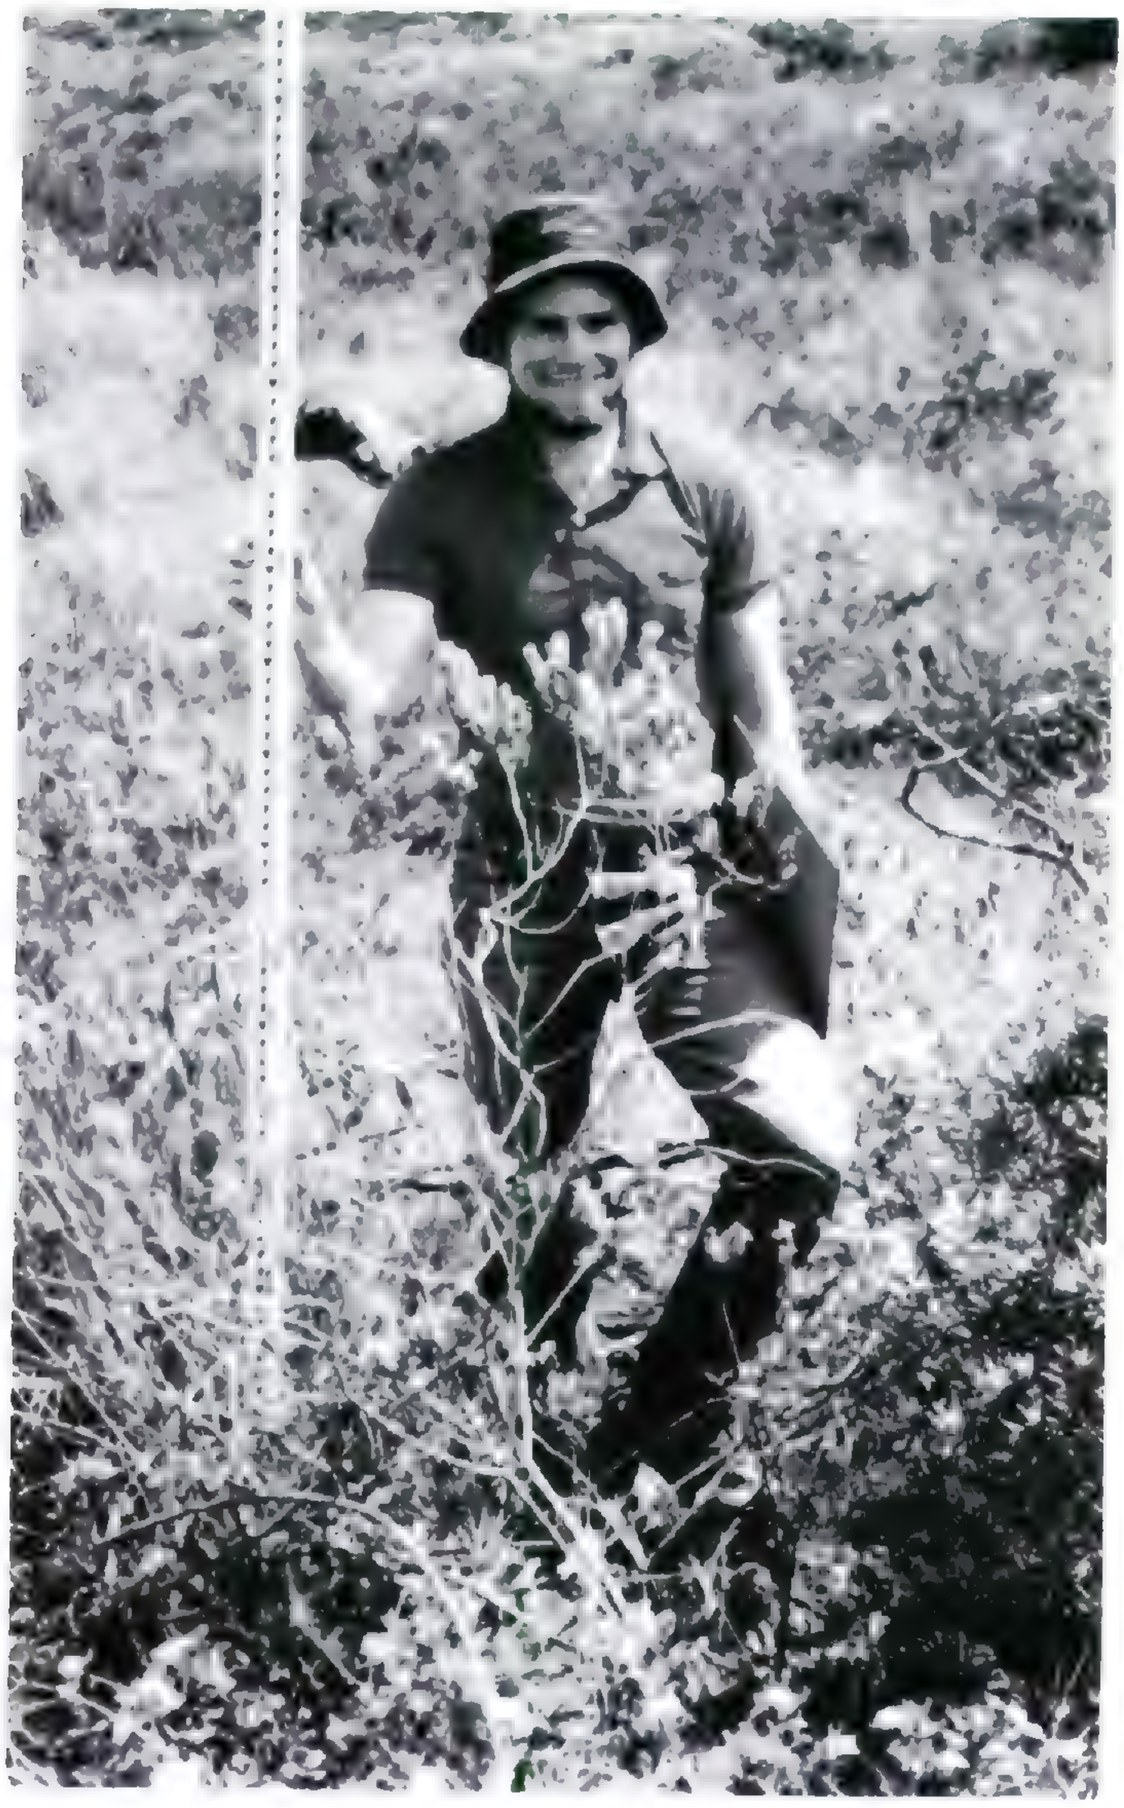

FIGURE 2. General habit of *Tetramolopium arenarium* subsp. *arenarium* var. *arenarium* within the Kipuka Kalawamauna Endangered Plants Habitat, Pohakuloa Training Area, Island of Hawaii, Hawaii. (Scale in decimeters.)

leaves). The only other member of sect. *Sandwicense* that occurs on PTA is *Tetramolopium consanguineum*.

Tetramolopium arenarium is composed of two subspecies, both presumably extinct: subsp. *arenarium* on Hawaii and Maui and subsp. *laxum* on Maui (Lowery, 1986). *Tetramolopium arenarium* subsp. *laxum* has open, lax inflorescences, flexuous pedicels, granuliferous-glandular achenes, and foliage that retains its yellow-green color when dried. In contrast, *T. arenarium* subsp. *arenarium* has compact inflorescences, densely strigose achenes, nonflexuous pedicels, and brown foliage upon drying. *Douglas 3191* has compact capitula, densely strigose achenes, nonflexuous pedicels, and brown dried foliage.

Tetramolopium arenarium subsp. *arenarium* is separated into two varieties: var. *arenarium* and var. *confertum*. *Tetramolopium arenarium* subsp. *arenarium* var. *confertum* has dentate leaf margins, and involucres 4–6 mm wide and 2–3 mm long. *Tetramolopium arenarium* subsp. *arenarium* var. *arenarium* has entire leaf margins, and involucres 6–9 mm wide and 3–5 mm long. *Douglas 3191* has entire leaves and involucres that are 6–7 mm wide and 4–5 mm long.

We verified our collection by comparing it with two specimens of *T. arenarium* subsp. *arenarium* var. *arenarium* at the U.S. National Herbarium (US): *Mann & Brigham 519*, collected at Puu Hualalai; and *Hillebrand 319*, which has no locality information. Both of these specimens were annotated by Lowery (1986) as *T. arenarium* subsp. *arenarium* var. *arenarium*. Lowery (1986) stated the lectotype for this taxon was "Hawaiian Islands: Hawaii: 1840, U.S. Exploring Expedition (US!, mixed collection with isotype of *T. arenarium* subsp. *laxum*)." The staff at US could not locate nor has any record of this specimen; thus, we were unable to compare our specimen with the lectotype.

Tetramolopium arenarium subsp. *arenarium* var. *arenarium* has no federal or state protection, because it has been listed as extinct by the U.S. Fish and Wildlife Service, Office of Endangered Species, Region 1 (Andy Robinson, pers. comm.). The U.S. Army, however, has begun a protection program for this taxon at PTA.

Herbst & Fay (1979) reported that grazing and browsing by feral animals, cutting for camouflage by military units, trampling by foot traffic or vehicles, and accidental fires set by hunters and/or military ordnances may adversely affect the three endangered plant species found at PTA. Our observations indicate that the most likely threats to the endangered plant species and the *Tetramolopium arenarium* population are from feral animals, fire, and competition from invading, introduced plants. We have observed numerous feral sheep, goats, and hogs in the endangered plants habitat. Also, the area has been burned (date unknown). We have not observed off-road vehicular traffic, foot traffic, or cutting of vegetation for camouflage. Fencing, removal of all feral animals, reduced use of the area for training, and continued efforts by the Army to control fires may help protect these plants.

We are researching the ecology and population biology of the endangered species and *Tetramolopium arenarium* with funding from the U.S. Army. Propagation of the species is being investigated as a means of ensuring its survival.

This research was funded by the U.S. Army Corps of Engineers, Engineering & Housing Support Center (CEHSC-FN), Donald M. Bandel, Chief of Cultural and Natural Resources. We appreciate

the assistance and encouragement given us by Col. E. T. Teixeira, Commanding Officer, PTA, and the men and women under his command. We also thank K. A. Schulz, E. D. O'Regan, and E. Weglinski for field assistance, the Colorado State University Herbarium (CS) for handling specimens, and D. H. Wilken, B. Berg, and E. L. Painter for assistance with this manuscript.

MISCELLANEOUS CHROMOSOME COUNTS IN ASTERACEAE, BIGNONIACEAE, PROTEACEAE, AND FABACEAE

Since the publication of my review of the chromosome cytology of the Fabaceae (Goldblatt, 1981a) and the documentation of the original chromosome counts cited therein (Goldblatt, 1981b), I have made several more counts in the family. These are reported here with associated collection data (Table 1). Most of the counts are particularly noteworthy as they are either the first records for genera or the first for species.

Counts are also reported for species of Asteraceae, Bignoniaceae, and Proteaceae. The significance of the counts in relation to the existing cytological record is briefly discussed for each species.

Material and Methods

All counts were made from root tips of germinating seeds, grown in the greenhouse. All seeds were collected in the wild for this study. Tips were harvested in midmorning and pretreated in either 0.001 M aqueous hydroxyquinoline for 6–8 hr. at refrigerator temperature or in saturated aqueous M-bromonaphthalene for 4 hr. at room temperature. After rinsing in tap water, the tips were fixed for 2–3 min. in 3 : 1 absolute ethanol : glacial acetic acid, rinsed again in tap water, and then hydrolyzed in 10% HCl for 6 minutes at 60°C. Root apices were squashed in FLP orcein (Jackson, 1975). The species studied and collection data are listed in Table 1, in which the diploid numbers are presented.

Discussion

ASTERACEAE

Of the estimated 48 species of the Old World and predominantly African *Dicoma* (tribe Mutisieae), only an Indian species, *D. tomentosa* Cass., has been counted, Bhandari & Singh (1977) having reported $2n = 22$. The report here for the southern African *D. schinzii* provides additional support for assuming a base number of $x = 11$ for the genus, although $x = 9$ is almost certainly basic for the tribe Mutisieae as well as for the entire family (Raven, 1975; Goldblatt, 1987).

PROTEACEAE

Already counted as *Aulax cneorum*, the record here of $2n = 22$ in *A. umbellata*, confirms de Vos's (1943) report of $n = 11$ in *Aulax*. Other African Proteoideae have $x = 12$, except *Leucadendron*, which has $x = 13$ (de Vos, 1943; Williams, 1972). *Aulax* and *Leucadendron* are the only dioecious African Proteoideae, and the karyological data support the contention, based on other criteria (Rourke, 1987), that dioecism evolved independently in the two genera and that they are not closely allied.

BIGNONIACEAE

The count here of $2n = 40$ for *Parmentiera valerii*, the first record for this species, is consistent with the number reported for three other members of this neotropical genus of tribe Crescentieae (Goldblatt & Gentry, 1979).

FABACEAE

The count for *Zenia insignis*, a taxonomically isolated and apparently primitive member of Caesalpinieae–Cassieae, accords with the putatively basic chromosome number for the tribe, $x = 14$ (Goldblatt, 1981a).

In Papilionoideae, $2n = 20$ in the monotypic *Graziodendron* is consistent with other numbers recorded for Dalbergieae, including the closely related genus *Andira* (Goldblatt, 1981a). *Pterocarpus*, also considered closely related (de Lima, 1983) probably has $x = 11$, but at least two species also have $n = 10$ (Goldblatt, 1981a). The diploid numbers for the previously uncounted *Chadsia* and for *Lonchocarpus pycnophyllus*, $2n = 22$, accord

TABLE 1. Chromosome counts reported here for Asteraceae, Bignoniaceae, Proteaceae, and Fabaceae, with collection data.

Species	Diploid chromosome numbers $2n$	Collection data

		DALBERGIEAE
Graziodendron rio-docensis Lima	20	Brazil, Espírito Santo, Linhares, *de Lima 1928* (RB)
		TEPHROSIEAE
Chadsia grevei Drake	22	Madagascar, Fort Dauphin-Tulear, *Dorr et al. 4075* (MO)
Lonchocarpus pycnophyllus Urban	22	Dominican Republic, Peninsula de Barahana, *Zanoni & Pimentel 26349* (MO)
		ROBINIEAE
Poissonia hypoleuca (Speng.) Lillo	ca. 32	Argentina, Jujuy, Río San Lorenzo, *Vervoorst s.n.* (no voucher)
		DESMODIEAE
Brya buxifolia (Murr.) Urban	22	Dominican Republic, Prov. San Juan, *Zanoni & Mejía 19785* (MO)
		PHASEOLEAE–ERYTHRININAE
Neorudolphia volubilis (Willd.) Britton	22	Puerto Rico, *Vivaldi s.n.* (no voucher)
		PHASEOLEAE–PHASEOLINAE
Neorautanenia brachypus (Harms) C. A. Smith	22	Zimbabwe, Wedza, *Corby 727* (SRGH)
		AESCHYNOMENEAE
Pachecoa prismatica (Sesse & Moc.) Standley & Schubert	20	Mexico, near Vera Cruz, *Norman 801* (F, GH)

with the presumed base number for Tephrosieae, $x = 11$ (Goldblatt, 1981a). In the previously uncounted genus *Poissonia* (tribe Robinieae), *P. hypoleuca* has $2n = 32$, and this species appears to be tetraploid. Base number in Robinieae is either $x = 11$ or 10, but dysploidy is evident in the tribe, with $x = 9$, 8, and 6 recorded in some genera (Goldblatt, 1981a). A base number of $x = 8$ seems likely for *Poissonia*, a hypothesis consistent with the patterns of karyological variation in the tribe.

Basic chromosome number for Desmodieae is probably $x = 11$, but at least *Pycnospora* and the one species of *Brya* previously counted have $n = 10$ (Goldblatt, 1981a). This first count for *B. buxifolia* is consistent with the earlier record for the genus.

Basic number for Phaseoleae is $x = 11$, the number also probably basic for all eight subtribes (Goldblatt, 1981a). The counts here for *Neorudolphia* (Erythrininae), a monotypic genus previously uncounted, and *Neorautanenia brachypus* (Phaseolinae) are consistent with this pattern. The count for *Neorudolphia* is of interest in view of its possible relationship with the large genus *Erythrina*, which has $x = 21$. The chromosome number in *Neorudolphia* confirms data from other sources that it is probably not closely allied to *Erythrina*.

My count of $2n = 20$ in *Pachecoa prismatica* (Aeschynomeneae–Stylosanthinae), cited by Norman & Gunn (1985), accords with the base number of $x = 10$ in *Arachis* and *Stylosanthes*, two of the remaining four genera of the subtribe. *Arthrocarpum* is uncounted while *Chapmannia* has $x = 11$ (Goldblatt, 1981a, b). The last-mentioned two genera are most closely allied to *Pachecoa* (Norman & Gunn, 1985).

I extend my thanks to all those who provided the living material used in this study.

LEPIDIUM BOELCKEI AND *L. JUJUYANUM* (BRASSICACEAE), NEW SPECIES FROM JUJUY, ARGENTINA

Several new taxa and nomenclatural changes have been published (Al-Shehbaz, 1986; Boelcke, 1964, 1984, 1986) following the treatments of Thellung (1906) and Hitchcock (1945) on the South American species of *Lepidium*. The genus, which is represented in South America by probably more than 50 species, is in need of a comprehensive study. Species boundaries within certain complexes are artificial, and the variation of many taxa is poorly understood.

The two novelties described below were initially sent to Professor Reed C. Rollins for identification. I am grateful to him for making them available for my study. Each of these is known only from the holotype.

Lepidium boelckei Al-Shehbaz, sp. nov. TYPE: Argentina. Jujuy: Depto. Humahuaca, Cerro La Soledad, 3,500 m; 23 Jan. 1929, *S. Venturi 8859* (holotype, US 1549309). Figure 1a–c.

Herba perennis caudicibus lignosis simplicibus, 1–2 cm in diametro, caulibus villosis subdecumbentibus, 6 15 cm longis; folia basalia spathulata integra vel dentata; racemi floriferi subcorymbosi, fructiferi valde elongati; sepala oblonga glabra persistentia albo-marginata; petala alba; stamina 2; siliculae anguste ellipticae vel elliptico-oblongae, glabrae, obtusae vel retusae, 6–7 mm longae, 3–3.6 mm latae; styli exserti, 0.6–0.8 mm longi; semina oblonga, nigella, compressa, exalata, ca. 3 × 1.5 mm.

Perennial herbs, with a woody, unbranched caudex 1–2 cm diam. Stems few to several from the caudex, ascending to subdecumbent, villous, 6–15 cm long. Basal leaves spatulate, petiolate, obtuse to rounded at apex, attenuate at base, earlier ones entire, later ones dentate to subincised, 1.6–4 cm long, 3–8 mm wide, the blades glabrous or hirsute along the midrib; petioles flattened, densely hirsute, 1–2.5 cm long. Cauline leaves few, spatulate to oblanceolate, entire, attenuate and subsessile at base, 5–11 mm long, 1–3 mm wide. Inflorescences densely flowered, ebracteate, corymbose racemes, considerably elongated in fruit; fruiting pedicels ascending, densely puberulous to subhirsute, 5–7 mm long. Sepals oblong, persistent, glabrous, somewhat leathery, 2–2.5 mm long, 1.2–1.5 mm wide, with a conspicuous white margin 0.2–0.5 mm wide, repand to suberose in the distal half. Petals spatulate, white, rounded at apex, attenuate at base, 3–3.2 mm long, 0.7–0.9 mm wide. Stamens 2; filaments white, 2–2.5 mm long; anthers oblong, 0.7–0.8 mm long. Fruits narrowly elliptic to elliptic-oblong, conspicuously flattened, glabrous, wingless, obtuse to obscurely notched at apex, 6–7 mm long, 3–3.6 mm wide; style exserted, 0.6–0.8 mm long; stigma entire, wider than the style. Seeds oblong, blackish, wingless, flattened, ca. 3 × 1.5 mm.

Lepidium boelckei, which is named after Dr. Osvaldo Boelcke, authority on the Argentinian Brassicaceae and author of several species of *Lepidium*, is easily distinguished from all of the perennial South American species in having narrowly elliptic fruits 6–7 mm long, persistent sepals with a broad white margin, conspicuous styles well-exserted beyond the apical fruit notch, and subdecumbent stems from a thick woody caudex. The Brazilian *L. grandifructum* C. L. Hitchc. is the only other South American species with fruits as large as those of *L. boelckei*. However, the former is a robust, erect plant with caducous sepals, six stamens, and included styles. Evidently, the two species are unrelated, and *L. boelckei* has no close relatives.

Lepidium jujuyanum Al-Shehbaz, sp. nov. TYPE: Argentina. Jujuy: Depto. Humahuaca, Tres Cruces; 3,750 m; 6 Apr. 1973, *Barbara Ruthsatz 506/7* (holotype, GH). Figures 1d–h, 2.

Herba perennis caudicibus tenuibus simplicibus; folia basalia longe petiolata, oblonga vel oblongo-oblanceolata, laminis 13–23 mm longis, 6–10 mm latis, serrato-crenatis, superne villosis, petiolis persistentibus, 3–4 cm longis, in dimidio proximale stramineis, valde alatis, glabris, in

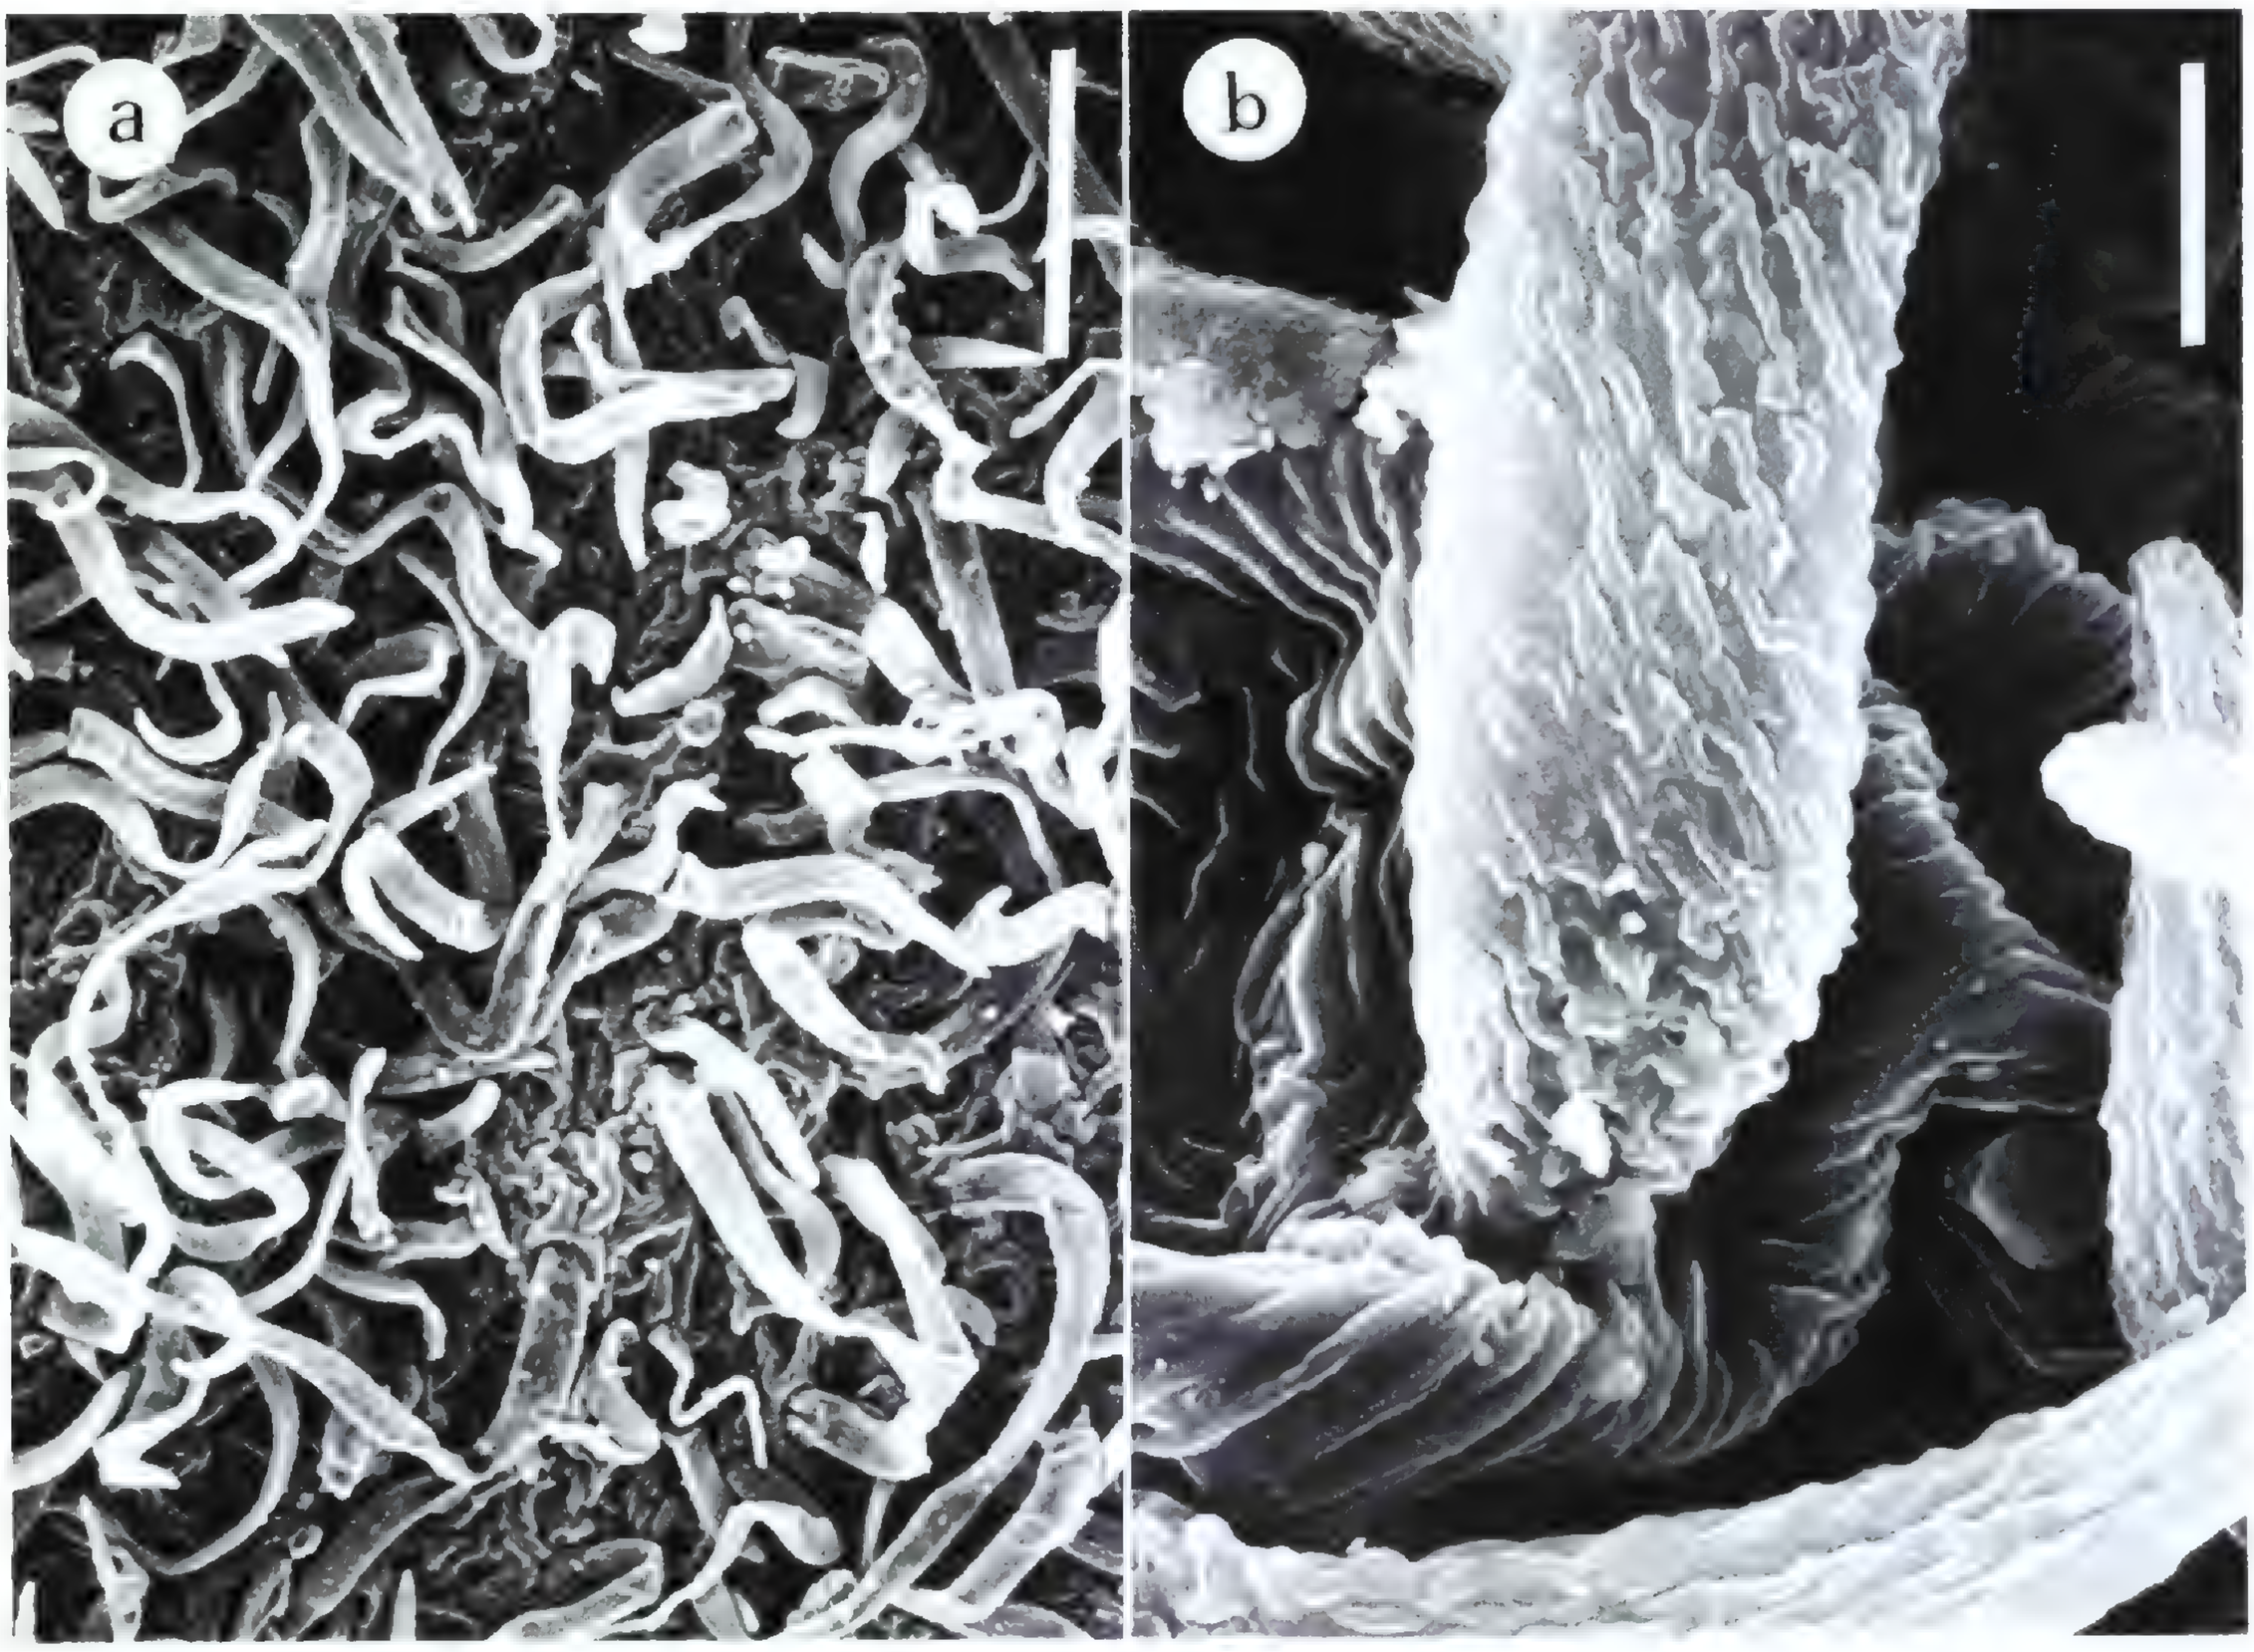

FIGURE 2. Leaf trichomes of *Lepidium jujuyanum*. Scales: a = 100 μm; b = 10 μm.

dimidio distale exalatis, villosis; sepala papyracea, persistentia, 2–3 mm longa; petala alba; stamina 2, filamentis basi valde dilatatis; siliculae rhomboideae, glabrae, emarginatae, 3.5–4.5 mm longae, 3–4 mm latae; septum in dimidio apicale peforatum; styli exserti, 0.6–0.8 mm longi; semina ovata exalata, 2–2.4 mm longa, 1.4–1.6 mm lata.

Cespitose perennial with an unbranched, slender caudex. Stems few, glabrous, 1.5–6 cm long, much shorter than the basal leaves. Basal leaves long-petiolate; blades oblong to oblong-oblanceolate, 13–23 mm long, 6–10 mm wide, serrate-crenate, obtuse at apex, cuneate at base, glabrescent below, villous above with crisped, subappressed, simple trichomes, the midrib prominent in the proximal half; petioles persistent, 3–4 cm long, the distal half green, villous, slender, wingless, the proximal straw-colored, glabrous, with 2 conspicuous lateral wings to 1.2 mm wide. Cauline leaves few to several, similar to the basal ones but gradually reduced in size upward. Inflorescences ebracteate, corymbose racemes, slightly elongated in fruit; fruiting pedicels divaricate, usually straight, densely villous, 4–7 mm long. Sepals oblong to slightly obovate, papery, persistent, spreading, membranaceous and entire to repand at margin, sparsely pubescent in the middle, 2–3 mm long, 1.5–1.8 mm wide. Petals spatulate, white, rounded at apex, 2–2.6 mm long, ca. 1 mm wide. Stamens 2; filaments white, 1.4–1.6 mm long, considerably dilated at base; anthers oblong, ca. 0.6 mm long. Fruits rhomboid, 3.5–4.5 mm long, 3–4 mm wide, with an apical notch

0.3–0.4 mm deep; valves glabrous, thin, obscurely veined; septum membranaceous, perforated at apex; replum 1–1.2 mm wide; style exserted from the apical notch, 0.6–0.8 mm long. Seeds ovate, flattened, dark brown, wingless, 2–2.4 mm long, 1.4–1.6 mm wide; cotyledons incumbent.

Lepidium jujuyanum, which is named after Province Jujuy, Argentina, belongs to the *L. meyenii* Walp. complex, of which the component species are perennials with exserted styles. The new species is easily distinguished from all the South American lepidiums in having long-petiolate leaves with villous, crenate-serrate blades and straw-colored, conspicuously winged, persistent petioles, strongly dilated filament bases, perforated septa, and rhomboid fruits with exserted styles.

ERRATUM

This is an *erratum* for the R. J. Rodin volume, *The Ethnobotany of the Kwanyama Ovambos*, published in 1985 by the Missouri Botanical Garden. APONOGETONACEAE; *Aponogeton* (pp. 50, 147): the description given on p. 50 is for *A. junceus* Lehm. subsp. *junceus*, not *A. rehmannii* Oliv. See H. van Bruggen (1973) Bull. Jard. Bot. Nat. Belg. 43: 191–233.

Instructions for Authors, *Annals of the Missouri Botanical Garden*

The *Annals* publishes original articles in systematic botany and related fields. Text may be in English or Spanish. When in Spanish, an English abstract in addition to a Spanish abstract is required. Short papers, especially nomenclatural matters and new taxa, are treated as "Notes," which have their own format as described below. Authors are urged to contact the editor prior to submitting manuscripts. Manuscripts sent already reviewed and revised are generally subject to the full normal review process initiated here. Manuscripts not properly prepared may be returned for revision prior to review. This includes manuscripts with improper abbreviations or with diacritical marks not indicated.

Page costs are $80 per page, although charges may be reduced under certain circumstances. Corrections in proof will be billed nonnegotiably to the author at $2.50 per line.

Manuscripts must be typed (output from dot matrix printers must be entirely clear) on one side of nonglossy 8½ × 11 inch paper. Leave at least one inch as margin all around, except on the first page. There three inches should be left blank at the top. **The text should be double-spaced or triple-spaced throughout,** including abstract, notes, legends, tables, specimen lists, Literature Cited, and footnotes. **Do not justify the right-hand margin, and do not break words there.** Italics, boldface, or other special typefaces should not be used—they will appear later as communicated to the printer by the editor. Words to be set in italics should be underlined. **Accents, umlauts, and other diacritical marks are the responsibility of the author.**

Footnotes should be typed double-spaced as paragraphs on the first page. The first footnote contains acknowledgments, including information on granting agencies, and herbaria that loaned specimens. The second footnote is the author's address. Addresses for additional authors are each separate additional footnotes. No other footnotes are permitted, except footnotes in tables, and these are best avoided. In papers formatted as "Notes," there are no footnotes: the acknowledgments make up the paragraph preceding the Literature Cited section, and the author's name and address make up the last paragraph of the article. In Notes, the names and addresses of multiple authors are all placed in the same paragraph.

Long, complex tables are discouraged. Tables not neat and easily understood will be returned for improvement. Leave out vertical lines, and avoid horizontal lines. Lines are added as needed by the editor and/or printer. Type table captions double-spaced as paragraphs at the tops of the tables.

A concise abstract should accompany each paper other than "Notes."

Periods are used after all abbreviations (which should be minimized) except metric measures, compass directions, and herbarium designations. States are not abbreviated, and cities are usually spelled out, although "St." is acceptable. **Abbreviate periodicals according to *BPH* (*Botanico-Periodicum-Huntianum*), authors according to *The Draft Index of Author Abbreviations Compiled at the Herbarium, Royal Botanic Gardens, Kew*, and books according to *Taxonomic Literature*.** Note, however, that book abbreviations are to be capitalized, and that books listed in the Literature Cited section should have their titles spelled out when feasible. Note further that names of taxonomic authorities may be spelled out in major taxonomic citations such as the formal citation at the head of a taxonomic treatment. Except by prior arrangement with authors not having access to crucial references, the editor does not provide the service of looking up abbreviations.

In the Literature Cited, periodicals should be listed as follows: author's last name, initial(s). Year. Full title of article. Journal abbreviated as in BPH. Volume: pages. Do not give parenthetical part numbers after volume numbers unless each part is paginated separately, which is unusual. For more than one author, follow this style: author's last name, initial(s), second author's initial(s), last name & third author's initial(s), last name. Citations of books should appear as follows: author's last name, initial(s). Year. Full Title (edited by Editor), 3rd edition, Volume 2. Publisher, Place. Citations of work "in prep." and similar references to inaccessible sources are strongly discouraged. Except by prior arrangement when necessary, the editor does not perform library research to fill in missing bibliographic information.

A brief Latin diagnosis for each new taxon is preferred to a complete Latin description.

Use one paragraph per basionym as follows: *Taxon* author, literature citation, type citation, e.g., *Bauhinia dipetala* Hemsl., Diag. Pl. Nov. 1880. *Casparia dipetala* (Hemsl.) Britt. & Rose, N. Amer. Fl. 23: 216. 1930. TYPE: Mexico. Veracruz: Valle de Cordóba, *Bourgeau 1713* (holotype, K; isotypes, F, GH, P, US). Exclamation points are not used for specimens examined. Indicate unseen types as "n.v."

Keys should be dichotomous, indented, and consistent with descriptions. Couplets should be numbered as 1a, 1b, 2a, and so forth.

Cite specimens as follows:

Additional specimens examined (or *Selected specimens examined* or *Paratypes*). MEXICO. OAXACA: Sierra San Pedro Nolesco, Talea, 3 Feb. 1987 (fl), *Jergensen 865* (BM, G, K, US). Dates and reproductive status are optional.

Send copies of illustrations; do not send originals until requested if the manuscript is accepted. Illustrations will be returned after publication. All illustrative materials should be mounted on stiff cardboard. The maximum size for printed illustrations is 5½ × 8¼ inches. Presize illustrations to fit either column width (2⅝ inches or ca. 68 mm) or full page width (5½ inches or ca. 140 mm). Figures are numbered in Arabic numerals in the order of their citation in the text. Parts of figures are labeled with capital letters. Photographs should be black-and-white prints. Transparencies and negatives are not accepted. Group figures into composite plates when possible, and abut edges of photographs. Do not use stripping between plate or figure segments. Make sure edges are squared. Maps should include reference to latitude and longitude. Scale bars should appear on illustrations, on photographs, and on maps. Magnifications/reductions indicated in captions are unwelcome to the point of usually not being accepted. Scanning electron micrographs should be free of conspicuous charging. Axes on graphs are all labeled. No explanatory text is to appear in figures. Rather, provide clear captions in sequential paragraphs apart from the other text, one paragraph for each group of figures, and following the style in current issues of the *Annals*.

For other aspects of style, consult a recent issue of the *Annals*; the latest edition of *The Chicago Manual of Style*; or write the editor. Communication with the editor at all points of the publication process is encouraged.

Manuscripts (**three copies**) and correspondence should be addressed to the Editor, *Annals of the Missouri Botanical Garden*, P.O. Box 299, St. Louis, Missouri 63166, U.S.A.

ANNALS OF THE MISSOURI BOTANICAL GARDEN

VOLUME 76
1989

Colophon

This volume of the ANNALS of the Missouri Botanical Garden has been set in APS Bodoni. The text is set in 9 point type while the figure legends and literature cited sections are set in 8 point type.

The volume has been printed on 60# Warrenflo (No. 1) and 70# Vintage Gloss (Nos. 2, 3, 4). These are acid-free papers designed to have a shelf-life of over 100 years. Vintage Gloss is manufactured by the Potlatch Paper Company. Warrenflo is manufactured by S.D. Warren Paper Co.

Photographs used in the ANNALS are reproduced using 300 line screen halftones. The binding used in the production of the ANNALS is a proprietary method known as Permanent Binding.

The ANNALS is printed and distributed by Allen Press, Inc. of Lawrence, Kansas 66044, U.S.A.
